No one has ever maintained that in mere descriptions we have a sufficient record of the changes produced by disease in the organs of man and of animals. From Morgagni to Cruveilhier the same remark is strictly applicable; they leave a something to be desired; they are not, they never can constitute, sufficient records of diseased structure. Valuable, no doubt, and never to be omitted, they can only be looked on as aids to more efficient methods. Many, however, maintain a different opinion in regard to the value of drawings or paintings in water or in oil colours, and some may even think them equal in value to any other form of record we now possess. I shall therefore take the liberty of making a few remarks on the supposed value of drawings, coloured or otherwise, as a substitute for actual structures or models, and casts in relief, made from the actual structures, and coloured after nature. Those who maintain that oil, and especially water-coloured drawings, are of great value as anatomical records, are not, I think, practical men. I say this with great deference, however, for I know amongst them men of the very highest reputation for what is usually called practical knowledge, that is, men who are of the very highest rank as practical physicians and surgeons. But what I mean is this, they have had no opportunity of testing their favourable opinion of water-coloured drawings. Had they taught pathological anatomy to large classes, as I have done, not merely of students but of medical men, a vast number of whom were their own contemporaries, they would soon have learnt the inadequacy of such representations in conveying to the mind of a general audience any *solid durable impressions*. I understand that it is very generally admitted by artists, and others who have studied this matter, that no vivid and correct idea of any object, *which should be seen in relief naturally*, can ever be conveyed to the mind by a representation on a flat surface; there seems to be a peculiarity in our visual perceptions in this matter. Pictures are deceptions, not realities: they do not even aim at deceiving so far; wax or plaster models in relief represent the actual object in all its rounded or angular forms: there is no deception here as regards mere sight, the perceptions are consequently just, deep, and lasting; the shadows natural, not mere surfaces painted of a dark colour to deceive the eye, as in drawings. In the model in relief as executed by Dr. Thibert, whose ingenious discovery it is the chief object of the lecture to explain, every surface is coloured as in nature: in paintings or sketches every one knows it is not so, and cannot be so. It is absolutely useless showing pathological drawings to classes and students: they are not regarded; in fact, they do not teach; they are ineffective deceptions, and have very generally ceased to be employed. Now, as regards the pathology of such diseases, as appear on the surface, I can speak with equal certainty and decision. In my younger days, I read all the illustrated works on skin diseases, on eye affections, and on Syphilis and Syphiloid disease; also on that class of uterine affections, which are not within the range of direct vision, and I cannot say that I ever derived the smallest practical information from such works. The impressions seem all too vague. I have spoken with hundreds of medical men on this point, and literally with thousands of medical students, and they have very generally agreed with me. What I mean is this no lasting impressions can be derived from such source. A singular instance (repeated again, has been seen very lately in a London Hospital, occurred to me, so highly illustrative of the difficulty, not to say impossibility, of deriving any positive information from drawings, however faithfully made, however beautifully coloured, that I cannot forbear alluding to it. I mean the occurence of at least two cases of glanders in man, which were not recognised in a London Hospital, notwithstanding the great efforts of Dr. Elliotson to make the disease universally known. But, as if it had been intended that the question of the utility of coloured drawings, (water coloured,) should be settled at once, and for ever, two experiments were made, as it were directly with this view, the first by Dr. John Thomson of Edinburgh; the second by M. Cruveilhier of Paris.

Dr. Thomson, apparently being convinced of the inutility of description whether written or delivered *vivâ voce*, in conveying to others ideas of disease, and of diseased structure, and equally convinced by what he saw going on in the museums of Pathological Anatomy, that they also had proved a failure, next attempted the method of coloured drawings on the most extended scale. To effect this, he employed a Mr. (afterwards Dr.) Carswell, who for many years drew and painted for Dr. Thomson every form of pathological disease. This vast collection of paintings is said to have cost between 2000*l.* and 3000*l.* sterling, yet all to no purpose. Exhibited annually to a few students, they seldom think it worth while examining them, and never hope to derive any practical benefit from their inspection. Look at the great effort of M. Cruveilhier! I allude to his pathological work with figures, engraved and coloured after nature, with admirable descriptions superadded, and yet practical men do not value it!

It is now time that I should explain why the existing museums have also failed, though composed chiefly of the actual morbid parts, removed by operation or after death, deposited in preserving liquids of which the best no doubt are alcoholic liquors, somewhat diluted, and set up to the best advantage in crystal jars, secured as well as may be from evaporation, &c., hermetically sealed, if possible; others dissected, and dried and varnished, &c. &c.; all being still the actual diseased structures themselves, which it is attempted to preserve. On this point I shall be brief, contrary to the expectations, no doubt, of many, who might suppose that I would here enter into a laboured proof of the inutility of museums so formed. But, on the contrary, I shall be extremely brief; for

1st. The profession nearly, in a body, have declared them to be an entire failure, by never visiting them, in fact, by taking no interest in them whatever. This is notorious, and I could state some singular facts in support of it, were it necessary

2. Small collections of such preparations must be entirely useless to schools of medicine, even if they gave any accurate information, which they do not.

3. All structures immersed in spirituous or other preservative liquors, in time lose their *natural colour*, and suffer other injuries, as hardening, softening, corrugation, &c. &c.; in short, in a few months, they generally are scarcely recognisable, even by the person who set them up.

4. To particularise any class of morbid structures which suffer by immersion in spirits, and by loss of colour, alteration in texture, &c., become quite useless, is perfectly superfluous, seeing that the mischief extends to nearly every class. Admitting that in certain pathological changes, mere form is often the important point to be shown, yet even here the preparation has lost most of its value by loss of colour.

5. The form of the phial distorts the structures, giving rise sometimes to ridiculous mistakes, and always to error when the person examining is not well acquainted with the anatomy of the organ.

6. The knowledge of a valuable fact in anatomy bearing on practice or on science is limited merely to the museum in which the record stands. I myself visited Paris twice, merely on purpose to examine a single preparation.

7. To secure the preparation and set it up neatly, the dissection is generally delayed until it can be made at leisure, and thus on innumerable occasions I have seen, and regret to say have myself been the cause of disappointing hundreds of practical men from seeing the structures examined in a fresh state, the only time when they ought to have been examined by the whole body present: when shown some weeks or months afterwards, suspended in their crystal jar, they were totally useless, or nearly so.

8. When put up and secured carefully in their jars, the preparations cannot be taken down and examined without great expense and trouble.

9. And lastly, the renewal of the spirits, the re-setting up, the trouble and time, the making fresh sections, cause an expense which even wealthy corporate bodies begin to complain of as oppressive, and leading to no practical results.

These insurmountable difficulties lead practical men constantly to devise other means of preserving records of disease; above all, the existing museums have never been, and never can be of the smallest use to the profession. Look at Baillie's Collection in the College of Physicians, and at Hunter's in London, as forming pathological museums, deficient at least in four great classes of disease; namely, uterine, cutaneous, syphilitic, and eye diseases; for these the museums have always been totally useless; but it is now evident that they do not furnish practical results, even as collections of morbid anatomy; hence arise 1st., more lengthened descriptions; 2nd., pictorial representations; and these having also failed, at least in the opinion of those teachers, who are also anatomists and practical men, a third method came to be thought of, namely, modelling or casting in wax; also in plaster casts, painted with *wax painting*.

I have not seen the much praised, and no doubt extremely beautiful wax models of Florence, coloured after life, but I have seen two considerable collections in this country, and from these it is easy to judge of all others. The remarks I shall make on wax models are as follows:—

A wax model has an immense advantage over all manner of drawings whatever; it is a model in relief, or perhaps a cast, it does not absolutely matter which, coloured after life, and therefore perfectly calculated to give to the eye a just and a permanent impression. But models or casts of *healthy structure*, or of what we call plain elementary descriptive anatomy, ought not to be tolerated within the walls of any school of anatomy, and it gave me real pain to see, as I happened to do last summer, a medical student studying the brain from a wax model of the brain, within the walls too of a school eminent for practical men in every department of our art. I was afflicted to see so great a defect suffered to exist in an otherwise great and admirable institution, and I could with much pleasure have assisted in reducing these models, which have been so much praised by ignorant and thoughtless persons, and which are one and all of them incorrect, into the shapeless mass of wax out of which they were originally formed, that thus converted into tapers, they might give light—in their present form they only spread darkness. I have already explained myself sufficiently on this point; with all sound anatomists and surgeons, I hold all attempts at representing the regular or normal structure by any contrivance whatever, as quite destructive of the best interests of the students.

But the same objection does not lie against the modelling in wax pathological appearances or changes, whether on the surface or in the interior of the body; others do, however, and we shall find them neither few nor trifling.

For, 1st, the colouring gradually fades, and not only the beauty of the model vanishes, but its value is destroyed in a few years. 2d. All the wax models I have seen require to be protected by glass, and are therefore mere toys. They suffer then from heat, trifling accidents, as blows, from mere handling, from dust; they cannot be multiplied easily and cheaply, so as to be made available to the 20,000 medical men scattered over Britain;

they are not serviceable to humanity; their expense or cost forbids their general use. That some of the difficulties might be got over I do not doubt but never perhaps wholly so. The late Sir Charles Bell had a method of making some very beautiful models in relief: they were, no doubt, rather casts than models, and seem to have been made in this way; I say *seemed*, for he kept his method a secret from me at least. First, a plaster cast was made, and over this a layer of white wax was placed, and this was painted; but whether with oil painting or, what is more probable, with wax painting, oil not having been used at all, I do not venture to say. This wax painting, if it were so, has a good effect. It might be that certain of Sir Charles's models were merely plaster casts painted with wax painting. This mode of painting was, as it would appear, the only method used by the ancient Greeks and their imitators the Romans; they called it the encaustic method, because they exposed their pictures whilst painting to the action of a strong fire. Dust does not seem to injure them; but Sir Charles's models or wax paintings can neither bear dust nor fire.

Many years ago (in 1825-26) I made several attempts, aided by some artists, my students, to discover this mode of painting plaster or wax (but especially for obvious reasons plaster casts) with wax painting, but did not succeed. Mr. Benjamin Bell did so, however; but he also kept his method a secret. I believe I know the method now; but think it quite inferior, for many reasons, to the models I have now to speak of—those, I mean, made on the method of Dr. Thibert.

Rightly to understand, and therefore correctly to appreciate, this great work of art, the museums set up by Dr. Thibert in London and in Paris ought to be visited and carefully examined. Besides representing every form of disease, internal and external, so as greatly to resemble life, these plaster-painted models are of a hard and firm material unalterable by dust or handling, or by exposure to climate. The models of Dr. Thibert are not delicate toys requiring to be sealed up under glass, and shown occasionally as varieties never to be handled. The colours are indelible, and they are *oil colours*, the full import of which will be understood by all artists. The expense, compared with any other mode of forming a museum, is absolutely trifling. They may be multiplied indefinitely, and thus the improvement of an art, depending most frequently on pathological discoveries, will no longer remain shut up in the museums or cabinets of the mere anatomist, or buried in the metropolis, but be extended rapidly over Britain. Since I first saw Dr. Thibert's museum, forming, as it does, an absolute contrast with the existing pathological ones, I have often thought on the immense advantages which would accrue to humanity by their introduction into the various hospitals and medical schools of the empire; before me stand a series of models, illustrating to the life all the external symptoms, and the changes on the internal organs produced by that most frightful contagious disorder, acute glanders in man. Several years have now elapsed since the descriptions of its discoverer, Dr. Elliotson, have been before the public, and read by us all. French physicians and pathologists had given us spirited water-coloured drawings of the same disease, but all to no purpose, as it would seem, for I have myself, as I have already stated, witnessed the medical staff of a large hospital mistake the disease for erysipelas; and although I was aware the moment I saw it, that no such case had ever occurred to me, although I could not fix on its name, yet begged of them to consider well what it might be, assuring them that I had never seen such a case; they persisted in their false diagnosis until they were put to rights by the sheriff of the county. And yet all of us had read descriptions of this disease, and had examined drawings of the appearances by the first masters; still these did not enable any one of us to recognise the disease. Had the model made by Dr. Thibert, and now before me, been in the adjoining room, the result must have been different. Again, look at the recent medical history of malposition of the uterus, and think what a mass of mistakes, false diagnosis, erroneous, and sometimes destructive, treatment might have been avoided by the profession years ago, had these models been known to the profession, as they ought to have been; and how easily might they have refuted those claims to originality brought forward of late in a most unblushing manner by a Scotch physician!

Consider how accurately these models fix the correct ideal of pathological changes, putting an end to all doubts and unreasonable scepticism, and forming at all times a pivot or foundation on which the profession may base and calculate on future progress: then shall we cease to wander in circles. By these means only can we hope to render diagnosis perfect.

In advocating thus strongly the method of Dr. Thibert, it will not, I hope, be imagined that I recommend the removing from museums all anatomical specimens; on the contrary, there are many points of disease which can be well illustrated by the present method. Other structures again, perhaps all if possible, should be carefully and rapidly dissected in presence of those interested in the case, whether students or otherwise; the parts may then be secured unostentatiously, and at the smallest possible cost, in dishes, closed in and put aside for future reference, a number being put on corresponding to the model. All this may be done at scarcely a thousandth part of the present expense; as fresh diseases appear new models are added, the model and the fresh pathological specimen being carefully compared with each other. Hospitals and physicians the most remote from large towns, would in this way have before them rapidly every organic change which occurred; and thus would they have before them models of disease sure to enable them to diagnose with certainty. Many Metropolitan Hospital physicians and surgeons may derive benefit also, as the following anecdote will sufficiently illustrate:—A lady had consulted some of the first accoucheurs in town respecting a diseased state of the uterine system, which those gentlemen ascribed to the presence of a fibrous tumour. Some doubts were raised as to the diagnosis, and the case was referred to an anatomical surgeon. It so happened that both parties,—namely, the leading accoucheur, and the surgeon, visited Dr. Thibert's museum; the former disdained even to look at the models exhibiting uterine disease; the latter examined them with the highest interest, and, instructed by what he there saw, proved next day, on examining their patient, that the accoucheurs had mistaken a common malposition of the uterus for a fibrous tumour. Inordinate self-conceit is a sad drawback, even to the best instructed.

There is before me a series of models exhibiting at a glance the changes produced on various textures by scorbutus—a somewhat rare disease, but one which still does occasionally occur, and I cannot refrain from illustrating the advantages of this innovation by relating what happened a few years ago in a large Metropolitan Hospital. A distinguished London surgeon was examining these models with me, when, seeing a specimen of disease affecting the palate and upper jaw, he asked me particularly what it represented. Dr. Thibert's work showed it to be the representation of scorbutus, affecting that part of the body. My friend, however, the surgeon, assured me that in his case the person was affected with gout; nevertheless, the model gave him the most perfect representation of the case he had seen for many years previously. On mentioning the anecdote to a distinguished London physician, he related to me what he knew had occurred in the practice of Sir A. Cooper, and in presence of a large hospital staff. A scorbutic case, such as I now speak of, was mistaken by that eminent surgeon for a malignant disease of the mouth, hopeless in its results. On his leaving the ward, the servant in attendance, an old sailor, told the students that the case was merely scurvy—that he would cure it in a few days; which he did.

In conclusion; to practical pathologists I believe it unnecessary to recommend this innovation by any further arguments. They must have experienced as I have often done, vexation and disappointment on finding after the lapse of a few days and immersion in spirits, how irretrievably altered for the worse were the best preparations of morbid structures, more especially were lost the very points they had wished to display. Let these recollect what they have seen happen to specimens of pulmonary apoplexy, of acute pericarditis, of inflamed and ulcerated larynx, of acute dysentery. They have only to recollect what they must know, that by loss of colour after severe and fatal flooding the dissector, with young sight and abundant industry, has been unable to recognize a muscle from the adjoining aponeurotic, tendinous, and cellular tissues. In their hands, then, I may safely leave this matter. To the practitioner in medicine I would say, form proper pathological and diagnostic museums, and take them under your own charge; remove them from the hands of those who have no common interest with the profession; then, and then only, may we expect to find reversed the statement made by a distinguished physician, "Practical men take no interest in anatomical museums."

I had intended to say a few words respecting the objection which some distinguished friends have made to these models of Dr. Thibert, on the ground that they do not sufficiently represent structure. But a little reflection convinces me that such objections are not solid. Nothing in nature is recognized by *practical men*, by the medium of *structures*, that is, minute structure. No drawing represents in the slightest degree *minute structure*, and I am convinced that by reflecting on this point these gentlemen, whose opinions I highly value, will soon be convinced of the correctness of this view.

London, 16th May, 1846.

A COURSE OF LECTURES ON DISEASES OF THE SKIN.

By JAMES STARTIN, Esq., Surgeon to the London Cutaneous Institution.

LECTURE XVI.

ACNE.

According to Willan, and others.

GENUS.	SPECIES.
Acne.	Simplex Punctata Indurata Rosacea

As proposed by Startin.

GENERA AND SPECIES.	DIVISIONS.	FORMS.
ACNE		
Simplex Pustulosa Rosacea vel Erythematosa	Localis Generalis	Disseminata Confluenta Inveterata

Gentlemen,—The cutaneous disease which will this day engage our consideration, presents well-known external characteristics; inasmuch as the face is the part of the body chiefly affected, and consequently the malady is not only under the observation of the patient and his friends, but of the casual observer. This complaint, known commonly as the Pimply or Carbuncled face, Worm or Grub Pimples, Copper Nose, Grog Blossoms, Rosy Drops, &c., is designated *Acne* by most writers on maladies of the skin, though the distinct application of this term, to the forms of eruptions it comprehends at the present day, is due to Willan, who, as I have had occasion to observe, must be held answerable for the fitness of much of our cutaneous nomenclature. It is very uncertain whence the term acne is derived, or what is its precise signification. The Baron Alibert, with his customary poetic license, considered the meaning of the term as equivalent to the Latin sentence, "*vigor flos juventæ*," which would be instituting a comparison between the pimples of acne and the blossoming of youthful charms at the age of puberty. But it is useless to dwell upon verbal disquisitions, when as practitioners and pathologists, it is only necessary, that we should obtain a precise knowledge of the morbid phenomena which are to be ranged under any given denomination. ACNE may be defined to consist in a non-contagious chronic inflammation of the *sebaceous follicles* of the dermis, (chiefly of the face) demonstrated by increase or change in their secretions, the retention of which in

the follicle, commonly ends in the production of inflammation and tubercular pimples, slowly suppurating and ending in a small serous scab, each spot being accompanied with more or less surrounding redness, of a violet or brighter tint; which appearance is also continued in the small cicatrix following the healing process. The contents of the pimples may commonly be protruded from the follicle by pressure with the fingers in a filiform shape, resembling a white or yellowish worm, or grub, of varying dimensions and consistence; the point, or external extremity, being often of a dark or black colour, from contact with the dust and dirt of the surface; this secretion, when examined under the microscope, is found to consist of oily sebaceous matter, in which now and then a microscopic insect (the *acarus folliculorum*) and its exuviæ can be discovered. It is observable also that the eruptions of acne are successive, and tend to resolution, rather than the ulcerative process; but that the sebaceous depositions, the tubercular pimples, the suppurations, slight crusts, and cicatrices, are commonly found co-existing.

The animalcula alluded to in this definition was discovered in 1842 by DR. SIMON of Berlin, who describes it as an articulated insect of considerable size, $\frac{1}{100}$th part of an inch in length, and $\frac{1}{500}$th part of an inch in breadth, composed of annular segments which overlap each other from before backwards; to these eight legs are articulated, and it is provided with a small head, furnished with mandibles, and which can be retracted into the rings composing the thorax of the animalcule; unlike the *acarus scabiei*, this insect appears to produce very little irritation, and must not be regarded as the cause of the disease, the slight pruritus it occasions, not being observable in every case of acne; nor am I aware that any treatment of practical importance has hitherto been deduced from a knowledge of its existence. I should mention that DR. SIMON'S researches have been confirmed by ERASMUS WILSON'S subsequent accurate microscopic observations, but that my own labours in this department have been rewarded by no such successful result.

The *acarus folliculorum* and its exuviæ, which it is said frequently to cast off, may be occasionally discovered in accumulations of sebaceous matter squeezed from the large follicles of the healthy skin, and the insect, which is a *rara avis*, for the loan of which I am indebted to Mr. Queckett, of the College of Surgeons, will be shown after the lecture to those gentlemen desiring it, by Mr. Topping, microscopical curator.

Willan and Bateman, in their descriptions of acne, divided the disease into three or four species, which were named A. simplex, A. punctata, A. indurata, and A. rosacea. I have not materially deviated from this mode of considering the complaint, which you will observe on the chart before you, consists of three species, one of which is not comprehended in Bateman's division already mentioned, viz: A. pustulosa.

Like most other cutaneous diseases, acne may be local or general, and it may appear in a scattered, confluent, or inveterate form. The face, the shoulders, the neck, and chest, are, however, the parts of the body most frequently affected; though I have seen the disease pretty generally scattered all over the body, excepting on the lower parts of the extremities and on the hands and feet.

The two first species of the disease A. simplex, and A. pustulosa, simple and pustular acne, (the acne simplex, punctata and indurata of Willan,) belong almost exclusively to youthful life from puberty, till the age of 25, and in a few rare instances to that of 30; the last written species on the chart, A. rosacea, rosaceous acne, may also appear in young subjects, but it is most commonly developed between the ages of 35 and 55; no rank or condition appears to be exempt from the eruption of these local disfigurements, which, for the most part are mere indications of local congestion, or disordered action of the capillary circulation, occasioned by a derivation of blood from the surface, to supply the greater exigencies of other parts, organs, and functions, that for the first time commence their important offices in the animal economy, thus proving what is often observed in other diseases, that any increased local action in the capillaries of a part, has a direct influence in modifying the action of these vessels in any other portion of the body, with which such part may be connected by sympathy or function. There is seldom any derangement of the health in acne as a consequence of the complaint; the strong and robust appearing nearly equally prone to it with the weak and delicate, though of course the malady will be somewhat modified by any constitutional disorder; this exemption from general diseases we must observe, however, does not apply to the last species on the chart, called A. rosacea, which in most instances is to be traced to some visceral derangement; or in females to a change in the circulation connected with uterine irritation, derangement, or disease. Observation would lead me to conclude that some yet unexplained connexion exists between the cutaneous circulation in the face, which of course influences the diseases of the part, and changes or disorders occurring in the generative system of both males and females; this connexion is conspicuous in some of the lower animals, in common poultry, for example, the crest of the cock or hen, evidencing in a remarkable degree, by its colour and vascularity, the activity or absence of incubation. This remark is further verified, by the well-known production of acne simplex, in its most inveterate forms, by the indulgence in certain vicious habits; but whether the morbid derangement is direct or indirect in such cases, or in those of acne rosacea, from uterine affections as before mentioned, may be considered doubtful, as dyspepsia or chronic visceral disorders, particularly those of the liver, are often found coexisting; and such affections alone, are very commonly to be regarded as the influencing origin of acnous complaints, yet it is surprising how often Leucorrhœa in the female is an attendant symptom of acne—showing its connexion with uterine disorders; whilst in both sexes, the age of puberty, a congenital tendency, the aforesaid morbid habit, an addiction to fermented liquors, (beer being especially obnoxious,) over feeding on highly spiced dishes and crude vegetables, are more usually to be traced as attendants, and probable causes of the complaint; indeed, the latter influencing circumstances have been long since appreciated; CHAUCER our oldest, and not least observing poet, in his "Faery Tale," thus describes "the Sumpnour," the convent caterer:

> " A Sumpnour was there, with us in that place,
> That had a fire-red *cherubinnes** face;
> For *saucefleme*† he was, with eyen narrow,
> * * * * *
> With *scallèd*‡ browes black, and *pilled*§ beard
> Of his visage children were sore afeard.
> There na's quicksilver, litarge, ne brimstone,
> Boras, ceruse, ne oil of tartar none,
> Ne ointème that woulde cleanse or bite,
> That him might helpen, of his *whelkes*‖ white,
> Ne of the knobbes sitting on his cheeks
> Well loved he garlic, onions, and leeks;
> And for to drink strong wine as red as blood.'

But in justice to those afflicted with this often misjudged disfigurement, I must beg you will observe, that the intemperate are not its only victims, for the water drinker is by no means exempt; indeed I have fancied cases of acne rosacea have multiplied since the introduction of teetotalism, and this to an extent that has occasioned my regarding that species of abstinence as one of the predisposing causes of the disease, arising, probably, from the disorder it induces in digestive organs deprived, perchance suddenly, of an accustomed stimulus.

It is very difficult, either by drawings or models, to obtain an accurate idea of the appearances of acne, as the enlarged pores of the skin and the unctuous state of the surface can be scarcely represented—a fact apparently appreciated by Alibert in his splendid delineations of cutaneous diseases, as he has given but one meagre representation of the disorder under the name of *Dartre-pustuleuse Disseminea*, and for the same reason I have but few models to offer to your notice, and must therefore trust to my powers of description to render you familiar with the characteristics of acne.

Acne Simplex is so constant an appearance, to a greater or less degree, in both sexes in their youthful days, that unless it be of unusual extent or severity, it scarcely ever claims the attention of medical men or requires medical treatment, though it is sufficiently annoying at that period of life from the disfigurement it occasions. It consists in an eruption, sometimes sudden in its appearance, of hard conical-shaped pimples, varying from the size of a grain of mustard-seed to that of the largest pea; these pimples, or *vari* as they are technically called, are a little elevated above the surrounding skin, from which, on their first advent they are scarcely distinguishable in colour, though they are sometimes lighter, and the skin then appears as if it were stretched over some hard minute bodies beneath it, which have interrupted the circulation in the points implicated; when the hand is passed over the part thus affected, a sensation as of small shot beneath the surface gives better evidence than the eye of the presence of the eruption; there is also very often, as I have before mentioned, an unctuous oily state of the skin, and considerable enlargement of the pores, which occasions the adherence of dust, and gives the patient a sallow dirty appearance, besides insinuating itself into the follicle, and discolouring the superficial layers of the inspissated secretions it contains, so that when those deposits are forced from their containing crypt through the narrow opening of the pore in the cuticle, they assume the appearance of a thread, worm, or grub, with a black head, or extremity; as the disease advances, the spots I have described, which are so many small accumulations of sebaceous secretions, in their proper duct, become more or less inflamed and surrounded with a zone of redness of greater or less intensity, whilst suppuration is set up in some of them, and runs its course very slowly; and when at last a yellow point appears on the surface, and a discharge takes place, the matter is imperfectly formed, and can only be evacuated by considerable pressure, being sometimes like cheese curd, at others of the consistence of soft wax, and mixed with blood, whilst a considerable swelling or tubercle remains behind, and becomes covered for a few days with a slight yellowish lymphatic crust, which ultimately falls off, and discovers a violet-coloured indelible cicatrix, that takes years for its entire obliteration; many of the vari, however, do not follow this process, but appear to be re-absorbed, and during the whole lengthened continuance of this youthful blossoming the acne may be observed in all the forms I have cited, viz., as hard points, inflamed pimples, suppurating vari, crusted tubercles, and indelible minute scars on those spots where the disease has gone through the healing processes. Some of these stages of the disease have furnished Willan and Bateman with two of their species, which I have comprehended under this single description of acne simplex: I allude to A. punctata and A. indurata; the former term being given to the eruption when it consists of mere points, and the latter to inveterate forms of the disease, where several vari become confluent, and produce a large indurated, violet-coloured swelling, which suppurates very slowly, and much disfigures the parties affected, who for the most part are more advanced in life than those who are commonly attacked with the other forms of acne simplex; no practical result arises from considering acne indurata as a separate species, as it is to be found intermixed with most severe instances of the disease I have described.

I have already enumerated the causes of acne; but I must mention that very often the complaint seems entirely local, and rather indicates a sanguine temperament and robust health than the contrary. In young men, the face about the beard and whiskers is most generally affected. In young women, perhaps, the shoulders and forehead: though the whole or greater part of the upper portions of the body, the face, neck, and chest, in both cases may be the seats of the complaint. That species of acne, which I have denominated A. pustulosa, is a much more rare affection than the last mentioned; nor am I aware that it has been separately described. It differs but little from acne simplex in appearance; yet a minute examination affords sufficient characteristics in my opinion to entitle it to a separate consideration. It is distinguished commonly by a somewhat sudden eruption of red

* *Cherubinous, round.* † *Red pimpled.* ‡ *Scurfy.* § *Bald, scanty.* ‖ *Festerings.*

pimp' vari, more inflamed than those of acne simple .. and which are not usually intermixed with much follicular enlargement and sebaceous secretion. A considerable degree of pruritus and burning or stinging pain attends this complaint, which also suppurates more speedily, and with a greater abundance of secretion. It also breaks and discharges spontaneously, and with a greater disposition to superficial ulceration or eczemation around the opening than is no : manifested in acne simplex. This disease forms the connecting link between impetigo, porrigo and acne. Indeed, did it ever end in incrustation or become squamous, it would be deservedly considered as belonging to that complaint; but this is not the case, the eruption pursues an exactly similar course to acne simplex—commencing at puberty and ending, unless appropriate remedies are applied, at the age of 22 or 23; it is, however, a more rebellious disorder, and in my hands has proved much less manageable, yet it seldom or never leaves scars, but discharges a watery serosity for some days or weeks, and itches a good deal, until at length it dries up, without leaving much induration; and a succession of the same pimples and processes at distant and different points continue to be witnessed, each pimple pursuing a separate and independent course. It is in this form of acne that I have seen the whole body affected, though the face is its chief seat; and I have no doubt the complaint was comprehended by Alibert, in the disease he has designated Dartre pustuleuse disseminea, though the description he has given of it is not quite coincident with what I have detailed.

Acne rosacea, or, as I should prefer to call it, A. erythematosa (as the inflammation is of the nature of erythema) belongs in an especial manner to a more advanced age than the two former species. The nose is the usual site on which its first development is witnessed, a few bright red spots, accompanied with more or less troublesome irritation, manifesting themselves about the age of 35 in individuals who have deranged their digestive functions, by the pleasures of the table, or indulgence in fermented potations, or in females from derangements in the menstrual process or the approach of their critical period; by degrees the spots or pimples alluded to, enlarge the skin around them, become swollen and of the intense redness that accompanies erythema—when pustules, which seldom attain the size of those attending other varieties of acne, make their appearance on these inflamed portions of the integument and they undergo a slow suppuration accompanied, with a red, and congested state of the parts around, arising chiefly from a visible enlargement of the capillaries, and especially of the veins which remain constantly tortuous and injected; as one pustule disappears, others succeed, and run through the same separate and independent course, until at length, the face becomes covered with tubercular and most unsightly red or purple indurations, the nose occasionally becoming enlarged and hypertrophied to a degree that would justify the application of the soubriquet *naso*, as applied to Ovid of old, as the organ may attain twice or thrice its natural proportions. Occasionally, however, acne rosacea, becomes confined to a small space, and does not extend in the manner described, whilst in other instances, the eyelids, the lips, the mouth and gums, and even the ears, and neck, become implicated in the disease, giving the unhappy patient an appearance at once hideous and disgusting, as suppurations, crusts, and fiery redness are the usual attendants of the hypertrophied distortions of his features; thus constituting the divisions inserted on the chart. These severe cases very rarely occur where no hereditary cause is existing. At the present time, I know a family in which nearly every member is more or less affected, and the father and grandfather, as they assure me, "kept their colour even in the coffin." I wish I could present you with a model of the nasal organ of one of these individuals, which is at least four times the natural size, and of so inflamed and fiery an aspect as to merit most of the racy satire with which Falstaff assailed that of his friend, "one Bardolph," described by Fluellin to Henry V. as an individual "whose face is all bubuckles, and whelks, and knobs, and flames of fire," and looking on his nose as in the case of the individual to whom I have alluded, you might, as Sir John has it, "think of Dives that died in purple; for there he is, *in his robes*, burning—burning." Henry IV. Sc. iii. I made an essay, with the proprietor of this curiosity, to suffer me to take a drawing or a model, but I was obliged to abandon the attempt, or give irremediable offence.

Acne Rosacea in the young subject, is a somewhat different disease from the foregoing, resembling in every particular, save that of greater redness and inflammation, acne simplex already described. Another variety of acne, which Biett has termed *acne sebacea*, is a form of circumscribed lepra, psoriasis, or erythema, affecting the nose for the most part, and, as I have mentioned, when considering leprous diseases, resisting every means with which I am acquainted for its removal, except the destruction of the part with caustic, or residence by the sea, or long perseverance in the internal and external use of cod liver oil. The disease to which I have here alluded is a reddish, scaly, insulated patch, mostly on the nose, seldom or never manifesting pustules or tubercles, the secretions being either of a lymphatic or squamous nature; in the latter case, the morbid state of the cuticle seems to extend into the sebaceous follicles, so that when a portion is detached, it exhibits numerous small points or processes on its under surface.

I have now endeavoured to render acne and its varieties so familiar to you, that I think it can scarcely be necessary to say more on the diagnosis, as the complaint has so many characteristic marks; the only other diseases with which it can be confounded, if ordinary attention be paid, are *porrigo* and *impetigo* of the face, which have been already reviewed; or its twin sister *sycosis*, a malady affecting the beard and other hairy parts of the body, which will claim our future consideration. However, the origin, progress and duration of acne, the absence of scales and incrustations in the complaint, and the presence of the peculiar secretion of the follicles, with the animalcule occasionally found therein, will not fail to distinguish it from every other cutaneous disorder having the face for its occasional seat. With regard to the complications of acne with syphilis, scrofula, cancer, &c., I propose taking advantage of some future occasion, to give this portion of the subject all the consideration it merits, and which, in connexion with modification of the maladies heretofore described, I can assure you, will lead me into details that may rather be comprehended in a distinct course of lectures, than in the limited space to which I have allotted the description and properties of the uncombined diseases of the skin.

I shall conclude the subject of acne next week; as, were I now to commence a description of the treatment of the disease, I must detain many gentlemen, who have honoured me with their attendance, from other and more important avocations.

CASE OF TALIPES, OR CLUB FOOT, IN THE ADULT, SUCCESSFULLY TREATED.

By A. W. Close, Esq., Grosvenor Street, Manchester.

The elements and the practice of the healing art in the present era of its history seem to be alike convulsed. The whole system, from the circumference to the centre, feels the shock. Even the thoughtful and considerate practitioner finds it difficult to remain unmoved; but let him try to do so—let him collect his thoughts, scattered may be by the turmoil and scepticism which prevail around him—let him watch and patiently wait the progress of events: ultimately the weal of science will be promoted, and the very efforts intended to mutilate and destroy, shall consolidate and establish. In the present passing period he may select much that is good from the discordant forces at work without. Hydropathy, though it actively kill many of its unfortunate patients by doing too much, will fix his attention on the value and importance of hygienic measures, and of water, as an external agent, whose use has been too much neglected in this country.

Homœopathy, though it passively permit many of its confiding but deluded victims to perish, by doing too little, will equally teach him to confide in hygiene; to give less physic in some cases, particularly in those of a nervous or chronic character; to trust more to the vis naturalis, not always, by the bye, the vis medicatrix; and whilst he wisely rejects the universality of any curative law yet promulgated, particularly one so puerile and insensate as the "similia similibus curantur" of the homœopathist, he will grant that the attempt to discover a general law operating on the cure of disease, as gravitation and its modifications on matter, is not unsupported both by philosophy and analogy. "The discovery of Delpech led to a mania, the squint mania, then the club foot mania, the curved spine straightening mania, then came the stammering cure mania." Nevertheless, the operation of Stromeyer for the cure of talipes, a total improvement upon that of Delpech, is a great boon to humanity. Like many other good things it is liable to abuse, but when judiciously applied, never fails to afford great relief and satisfaction to the patient, and high gratification to the operator. Byron's biographers say that much of his moroseness and misanthropy originated in the affliction of this deformity. I can well suppose that it was so, for the awkwardness of gait is not only disagreeable to the eye of an observer, a circumstance which would peculiarly affect the mind of the haughty and unfortunately misled poet, but the mode of progression necessarily adopted by the sufferer is sometimes exceedingly painful and laborious.

Towards the end of last April I was requested to visit a gentleman at Green heys, who wished to consult me respecting a deformity of his left foot. Mr. P———, aged 35, has not been able to place his heel upon the ground since he was five years old. When he stands upright, the heel is raised from 2½ to 3 inches above its natural position, and it can only be made to touch the floor when the body is thrown backwards, and the left foot and leg placed considerably in advance of the right; and then only by the posterior facet of the os calcis. From the oblique direction in which the weight of the trunk has been brought to bear upon the tarsal arch, the bones of the tarsus are made to bulge upwards and forwards. This gives the appearance of displacement or malformation, and induced a gentleman of more than ordinary anatomical knowledge, whom the patient consulted some years ago, to state that such actually existed. The concavity of the arch is much increased by the just mentioned convexity of the dorsum, and by a tight cord like band at its inner side, formed by the contracted tendon of the flexor longus pollicis, and also by a general contraction of the plantar aponeurosis, extending from the metatarsus to the os calcis. By these means, likewise, the foot is drawn very much inwards, and brought into a condition midway betwixt the "equinus" and "varus." The tendo achillis is felt hard and tense—the muscles of the calf are shrunken and attenuated. The patient feels that the great impediment to the placing the sole of the foot down is the firm and stretched tendon inserted into the heel—this, too, prevents the free extension of the knee. Progression is performed on the plantar surface of the anterior extremity of the metatarsal bone of the little toe, and frequently on its outer edge. To meet the elevation of the heel, and the inclination of the foot inwards, the patient has worn a boot some inches thicker at the heel and outer side than at the inner. The contour of the foot when covered by the boot is irregularly oval, and not unlike that of the cow or horse; a circumstance, I suppose, which has given it the somewhat euphonical designation, "equinus." Mr. P. states that the act of walking is always laborious and distressing, and from the difficulty of getting a boot to fit, and the presence of corns, often very painful. The muscles of the leg are nearly inactive, and the advance or retrogression of the affected extremity seems to be effected by the muscles of the thigh attached below the knee, and into the patella. In short, the limb below the knee acts rather as a dead weight, than a useful member.

I at once held out the prospect of considerable improvement from the operation. Mr. Walker, surgeon to the Eye Institution, and Dr. Henry Reid afterwards saw the case with me, and although not so sanguine as myself as to a favourable result, they both concurred in the propriety of the operation.

On the morning of the 8th of May, the patient being placed on the face, with the assistance of Dr. H. Reid, who bent the heel downwards, I divided the tendo achillis by passing a tenotomy knife immediately under the skin; turning its edge upon the tendon, and cutting towards the deeper placed textures; its division was accompanied by a grating sensation, but not by the snap which is frequently heard. The absence of this, Dr. Little, very correctly I think, considers to indicate that the gastrocnemii are, prior to the operation, contracted to the utmost extent. The tendon of the flexor longus pollicis, and tenser portion of the plantar fascia, were divided in like manner. I had intended to apply

the extending force immediately after the operation' but finding that the edges of the incision made in dividing the tendo achillis would, by so doing, be kept so much apart as to interfere with their union by the first intention, I bandaged the foot in its deformed position, and in the afternoon applied a splint to the outside of the leg more securely to keep it so.

May 13.—On the 11th the incision being pretty firmly agglutinated, the instrument, which consisted of Scarpa's boot with the screw and unyielding iron rod, most admirably manufactured by the Messrs. Wood, surgical instrument makers of this town, was applied—but the extension was not commenced till yesterday, when it was slightly exerted, and to day increased, and the patient ordered to get up and walk about occasionally.

June 20th.—On the 11th day after the operation, the foot and apparatus being covered by a gaiter, Mr. P. went to and from his place of business in a cab; this he has uninterruptedly continued to do. The extension has been gradually and carefully increased. To-day, on attempting to turn the screw, it is found to have reached its last turn; the foot-board is, at the most acute angle it is capable of—the heel is as much down, the ankle as much bent, as that of the other foot—and the foot has lost its tendency to turn inwards.

On the 20th, he put on a pair of lace-up boots, which he was requested to keep on during the day, the apparatus to be applied at night, and two hours exercise in it to be taken every morning. On the 27th, he walked from his place of worship to his house, a distance of half a mile; and six days after he walked from the warehouse in town to his own residence, a distance of a mile and a quarter. He is now endeavouring to improve the mobility of the joint, and to correct the imperfection of gait and the unsightly associated actions of the muscles of the trunk and extremities, which have been produced by the deformity so long continued. In this respect, his own intelligence, to which I am much indebted for the rapid success already obtained, and time, will develop great improvement.

The early history of the case I endeavoured to obtain from the medical gentleman who attended the patient in his infancy. From him I could only learn "that to the best of his recollection it was mere weakness of the ankle joint." From other sources I am informed that "he was very delicate in infancy; and up to the age of three or four years he had frequent attacks in the bowels, at times very severe. The deformity was first noticed when he was about four years old. Various methods were used either to check or remove it. When between six and seven years old, lightly constructed irons, fastened to the sole of the boot, and reaching a little way up the leg, were worn; these appeared to do no good, and being troublesome were left off; binders were also used, and frequent applications of cold water." The deformity appears to have reached its maximum at the age of fifteen, or sixteen. It seems then, according to the theory propounded by Dr. Little, with which I am disposed to coincide, both as to the origin of congenital and non-congenital talipes, that the irritation of the mucous membrane of the alimentary canal, implied by the term "weak bowels", had so affected the incident and reflex nerves of the spinal chord, as to produce spasmodic contraction of the muscles of the calf. "The disturbance may continue a considerable time unheeded, or without suspicion of its tendency to induce secondary disease being awakened. By means of the chain of filaments on which the reflex functions of the nervous system depend, it may be inobtrusively exciting involuntary contraction, evinced by a scarcely perceptible limp, a tendency to fall on a certain wayward action in walking. At this period it frequently happens that if the foot of the child be examined when not actually engaged in walking or standing, no anormal condition can be conceived." Not to enlarge upon this particular, I may observe that the early history of my patient fully bears out this reasoning. And that it is a case of talipes from spasm, and not from paralysis, is rendered obvious by the fact, that after the operation, he had the power to flex the ankle joint, which he did not possess before. This is increasing. A few additional observations shall conclude this communication.

It is important to take care that every contraction likely to offer an impediment to the restoration of the foot to its normal state be removed. This intention should be fulfilled by a sufficient division of the resisting textures: at the same time the operator should keep the eye of his mind fixed upon the important parts which may be injured by a careless procedure.

I was advised by some very good authorities at first to use Stromeyer's foot board, a plan which was uniformly adopted by Dr. Little in all his adult cases; but I conjectured that an arrangement by the intervention of which the heel could be brought in contact with the ground, and have, at the same time, the superincumbent weight of the body, would be more consonant with the natural relation of the parts, and therefore more likely to prove successful. The result proves that I was not mistaken. A more uninterrupted, expeditious, and perfect cure of the adult is not on record.

The proper choice and application of the instrumental part of the treatment—its daily adjustment—occasional removal and re-application—the avoidance of violent and irregular extension, and of excoriations—are of equal importance with the operation itself.

The almost intolerable pressure produced by the footboard on a corn at the sole of the foot, for which Dr. L. recommends an air cushion, was immediately and effectually relieved by the occasional application of the arg. nitrat.

At the outset I mentioned that this operation is sometimes abused and misused.

I have known cases of talipes operated upon, and then submitted to the aid of a rudely constructed wooden splint. No wonder they have failed.

The operation has been performed in hemiplegic cases, when there existed not the possibility of success; sloughing, and a far worse state of matters than were present previously to the operation, ensued.

It has been practised on persons of a bad constitution, *bon vivans*, wine bibbers, those who should have had a preparatory treatment of six months, under the care of Priessnitz—sloughing—delirium tremens, and death followed.

Chiefly as an instance which may prove partially corrective of such folly, I offer the case now related to the readers of the Medical Times and to the profession.

Much might be added to the mode of, and best instrument for performing the division, but the sources of information on these points are in every one's possession; besides, every case will require the practitioner's wn judgment, dexterity and ingenuity.

FATAL PERIOSTITIS FROM THE INCIDENTAL EXTERNAL USE OF CORROSIVE SUBLIMATE.

By Robert Annan, Esq., M.R.C.S.E.

In his elaborate and instructive chapter, *Of Poisoning with Mercury*, Professor Christison * has given numerous examples illustrative of mercurial action, immediate and remote, in the human body, not the least interesting of which are, the testimony of Dr. Guerard to the production of ptyalism from the use of the warm bath of corosive sublimate, 1 ounce to 40 quarts of water; the case of Dr. Anderson, where from the external application of the same remedy, dissolved in rum, 30 grains to the ounce, severe symptoms, with ptyalism, were induced; and a case by Professor Syme, in which a solution of nitrate of mercury, rubbed by mistake on the hip and thigh in place of camphorated oil, was followed by intense pain, shivering, general disorder, and ptyalism, and afterwards exfoliation of the lower jaw; and lastly, the case of the German, by Dr. Scheel, affected with salivation, evidently mercurial, which proved fatal, but which it was impossible to trace to its real cause till after death, when a little leathern bag containing a few drachms of mercury, was found hanging at his breast, and which during six years had been frequently renewed, having been used as a protection against itch and vermin.

As a sequel to these, and illustrative, though in a somewhat different shape, of the effects, immediate and remote, from the incidental external application of corrosive sublimate, the following outline of a case may not be unacceptable to my medical brethren.

In the end of January, 1845, G. F., 38, married, a shepherd from his youth, of a very fair sanguineous complexion, after being employed several hours daily, for a succession of days, in washing or rubbing sheep affected with cutaneous disease, with a nostrum afterwards ascertained to consist of two drachms of corrosive sublimate, with mur. ammon. in about 20 ounces of water, was seized with sickness, vomiting, and constitutional irritation, and after the lapse of several days with ptyalism, though not particularly severe, by which he was confined for nearly a fortnight. About six weeks afterwards a similar attack was experienced from the same cause, leaving behind a considerable degree of debility and emaciation. He then resumed his out-door occupation, the weather being remarkably mild for the season, though occasional frosts were succeeded by broken weather. On inquiry, I learned from my patient that he had repeatedly before had occasion to apply, with his own unprotected hands, the same remedy, without till now being conscious of any bad effects on his person. During the spring months and the beginning of summer, he suffered, as I was afterwards told, from wandering pains in his joints, which were formerly seated in the left, and afterwards also in the right ankle. In June, I accidentally saw him, and then found the inferior extremity of the fibula of the left leg, to the extent of about fc inches, somewhat red, and swollen into a pyrifo shape, though locomotion was only slightly impeded. Leeching, with blisters, and other means were recommended, though, from circumstances not necessary to be here stated, I afterwards found that the advice had not been followed. In July, after trying of his own accord the effects of cold and warm sea-bathing, he consulted, by my advice, an eminent surgeon in Edinburgh, and blistering, and the internal use of the sol. hydriod. potass. were continued for two months without benefit, when he again visited the metropolis, and was seen by his former adviser and another surgeon, but still with no beneficial results. At this period, in addition to a considerable increase of the swelling and pain in the fibula of the left leg, a slightly elastic tumour, of the size of an almond, had appeared on the forehead towards the centre of the *os frontis*, and about two inches above the right eye, preceded for several weeks by severe pains, described as shooting through the head from the brow to the occiput. And some time thereafter, the tumour being slightly moveable, an opening was felt in the skull, one-third of an inch in diameter, as afterwards more fully ascertained, on the removal of the tumour at the desire of the patient. The opening included both tables of the skull, and the edges were only slightly rough or irregular. Though, at first, the incision made partially united, it did not entirely close, and continued to discharge till death. The disease in both ankles increased, with severe shooting pains in both metacarpi. Partial suppuration took place over the extremities of the fibula and tibia of the left leg, which was opened without affording relief. His nights were now nearly sleepless; cataplasms and opiates, in various forms, were used without benefit; and after much suffering, death closed the scene in the beginning of April, or about 14 months from the period of the first attack.

It is not undeserving of notice that, of ten sheep to which the nostrum had been applied by this man at his last attack, two died shortly after its application, apparently from the use of this powerful solution.

It is, perhaps, the easiest solution of this case to infer, as there was not the slightest reason to suspect the presence of syphilis, that, as probably occurred in the case by Dr. Scheel, the system had been more than once previously, though slightly, affected, by the repeated contact of the solution, and operating on a strumous habit, had finally given rise to the train of symptoms above narrated.

July 18, 1846.

* Treatise of Po , Chap. xiv.

INFECTIOUSNESS OF SYPHILIS IN ITS SECONDARY FORMS.

By M. D.

In the course of a conversation upon medical subjects, which I lately had with an army surgeon of great experience, now settled, in civil practice, in a country town, he mentioned the particulars of the annexed cases as illustrative of the infectiousness of syphilis in its secondary forms.

The facts detailed appearing to me of vast importance in the pathology of syphilis, I advised him to publish them as a contribution towards settling rather a vexed question upon a subject often involving the peace of families, and always exceedingly embarrassing to medical attendants.

His engagements in practice, however, only afforded him time to read his memoranda to me; but agreeing with me that the cases were interesting and instructive, he has permitted me to send them to a medical journal for publication.

As the subject had been recently partially discussed in another journal, in some notice of a medico-legal case, tried at the last assizes in Cork, I intended to send these papers to that journal; but having learned since my arrival in town that the circulation of the MEDICAL TIMES far exceeds that of the journal alluded to, and wishing to give the widest publicity to cases involving so much, I send them to you, and earnestly hope that, notwithstanding the constantly crowded state of your columns with the most valuable matter I have ever found in a weekly periodical publication, you will soon find a place for this communication.

It was my intention to add some remarks upon these cases, and upon the infectiousness of syphilis in its secondary forms, generally; but seeing that your hands are so full, I confine myself for the present, to sending you the simple statement of facts—facts that may be relied upon; trusting that at some future period you will allow me to resume the subject in your pages, and make some comments for the consideration of the profession.

There is one remark, however, which I think it right to make upon the present occasion. It is this: that I believe the husband had originally a chancre in the urethra obscured by the more prominent symptoms of gonorrhœa, which no doubt engrossed the attention of both patient and surgeon. I entertain this opinion because, in the course of a very extensive experience in public and private practice, I have never known gonorrhœa, however virulent, to be followed by secondary syphilitic symptoms; and I believe that in every case where such a result is reported to have taken place, there was a true syphilitic chancre somewhere, and most probably in the urethra, where in complication with clap such sores easily escape the notice of the surgeon.

The most important question for consideration in the annexed cases, is, *as to the period of time at which the wife became infected, and the medium through which the infection was communicated to her.*

A bachelor in a respectable station of life, and in the enjoyment of good health, contracted gonorrhœa, to get cured of which he put himself under the care of a respectable general practitioner, in a country town. In about six weeks he was pronounced well; but three months subsequently he felt a soreness in his throat, and perceived some blotches on his skin. For this he consulted one of the surgeons to the County Hospital, and upon examination it was discovered that the throat was ulcerated, and the disease was considered to be syphilis in a secondary form. The patient was put under a course of the usual treatment (mercurial), under which he got well. Having continued perfectly well for five or six months, he got married in the month of September, 1842. In a little better than a year from the date of the marriage the wife lay in of a healthy child, which has never experienced any interruption of health, and is to this day perfectly well. The wife fell with child a second time, and when about seven months gone, her medical attendant was called in on account of a sore throat, which had resisted domestic remedies. Upon investigating the case with caution, the throat was found ulcerated, and the surgeon had, in his own mind, no doubt but that it was a case of secondary syphilis. From the information that the surgeon could collect, by the most delicate, but, at the same time, most efficient inquiry, he came to the conclusion that the patient had not a primary sore—besides which she was a person *strictly moral, and above all suspicion.*

Inquiry was then made into the husband's state of health when the details of the affection before marriage were learned; and it was further discovered that he was, then, labouring under an inflamed throat, with a sense of dryness and constriction in the fauces, and that there was also a papular eruption upon the chest and neck, invading posteriorly the scalp under the roots of the hair. The husband had never been guilty of any infidelity towards his wife, and was positive that he never had, even before his marriage, any ulcer or excoriation upon the penis, and having been so long well, and free from all symptoms, he could not suppose that he was labouring under secondary symptoms, and would not submit to treatment, trusting that the affection was merely temporary, and would vanish without medical aid. The wife, however, used the remedies prescribed for her, and remained under a mild course of treatment from the 26th of November to the 26th of December, with manifest advantage. On the 5th of January she was delivered of a male child, apparently healthy, and of the full time, or nearly so. On the third day the child was found covered all over with a papular purple eruption. A consultation was immediately had with one of the physicians to the County Hospital. The physician suspended his opinion as to the nature of the disease till he paid a second visit; but then he concurred in the surgeon's views, that it was a clear case of syphilis. The child died on the third day from the appearance of the eruptions. The mother's throat, which had been mending under the treatment before her accouchement, began to get worse soon after she left it off; and it was deemed advisable, about a month after her delivery, to put her under a mild course of mercury. A slight ptyalism was produced, and kept up for nearly two months, when a cure was effected. The husband finding that he was getting worse, and witnessing the good effects of the treatment upon his wife, submitted to a similar course of mercurial treatment, and was effectually cured. Up to this time there has been no re-appearance of the disease in any form; but the wife, who became pregnant again, lay in of a six months' still-born child, without any assignable cause for such an event. Her health, as well as that of her husband, continues good.

ON THE CEREBRAL CIRCULATION—THE COMPRESSIBILITY OF THE CEREBRAL STRUCTURE—AND THE BEARING OF THESE POINTS UPON SOME CIRCUMSTANCES IN DISEASES OF THESE PARTS.

By J. S. FLETCHER, Esq., M.R.C.S.

(Continued from page 313.)

I think I have brought forward experiments and cases where, in the natural state of the cranium, this cavity has contained both an excessive and a diminished quantity of blood over the natural standard, and which I believe show that the contents of the cranium are, like other organs, under the influence of the atmospheric pressure to a very considerable extent. Were it not so, the amount of blood or fluid, both in health and disease, within this cavity ought at all times to be the same.

Having shown, as I believe I have done, that the brain can be drained of its blood, there yet remains the question as to whether this deficiency of blood is replaced by an equivalent amount of serum, as is usually said to be the case; but I feel certain that it is not. It is certain, that as the brain with its normal quantity of blood pretty accurately fills the cranial cavity, and that although it is not so perfectly closed as to prevent the atmospheric pressure acting upon its contents, still it will not admit of the ready access of air to occupy the space of any fluid that may be removed. We must have this space occupied by some substance; and if the removal of the blood be very gradual, as in many cases of disease, no doubt some serum will be exuded which will partly occupy this space; but in few, if any, cases am I inclined to believe that this is filled up entirely by serum. There is another means by which it seems most probable that this space is occupied, and that is by the resiliency of the cerebral structure itself. This is, I believe, the way in which, in all cases of sudden losses of blood, the place of the blood is occupied; and this accords with the states found in the crania of those animals bled to death in the experiments of Dr. Kellie and Dr. G. Burrows, also, that in one of the cases of death from hemorrhage which I have previously narrated, for in none of these cases was there any serum found within the skull, although the blood was drained away; and from this I conclude, that in cases of very rapid death from hemorrhage the brain will be drained of its blood, and no serum will be found in its cavity, except in the normal quantity; also, that by bleeding we can remove blood from the brain without its being replaced by serum.

If there be more than the normal amount of serum in the brain, it is stated that there will be a corresponding diminution in the quantity of blood in the cavity, but this I am convinced, is not correct—in which statement I think I shall be borne out by detailing the appearances I found in a case of sudden death from serous apoplexy, where the brain contained more than its normal amount of blood and a very large quantity of serum. "The vessels of the scalp contained a considerable quantity of blood. Within the cranium, the sinuses contained about the normal quantity of blood; the vessels of dura mater were much injected, the meningeal arteries were quite full of a dark-coloured fluid blood, and blood oozed from several points on the external surface; the cerebral veins were excessively congested. At the base there was a very considerable amount of serous effusion; there was at least eight ounces. The ventricles contained some serum, and the cerebral structure contained more blood than natural."

In this case, death occurred very rapidly, probably within two minutes from the time of seizure. Again, it is stated that if there be an excess of arterial blood, there is a proportional diminution of the venous, and *vice versa*. This statement rests upon the previous opinions which most authors had formed with regard to the circulation, and is in my opinion equally incorrect. There no doubt may be an excess of either venous or arterial blood in the brain. The case of simple apoplexy previously narrated is an example of the former; this may occur at any time, but an excess of one is not necessarily attended with a diminution of the other, as both kinds may be in excess at one and the same time.

Another question worthy of inquiry into is, as to the effects of position upon the blood within the head. The supporters of the opinions which I have been combating contend that it is not influenced by position, but both experiments and facts point out the opposite of this. Dr. Kellie killed two dogs by Prussic acid, and suspended one by the ears, and the other by the heels, and allowed them to remain eighteen hours, and he thus describes the appearances. "In the one suspended by the heels, the integuments and external vessels were greatly congested; in the one suspended by the ears, these parts were pale and the vessels empty. Within the head the contrast was but trifling. The sinuses beyond all doubt were loaded in the one suspended by the heels, and rather empty in the other."

Dr. Burrows repeated these experiments on rabbits, and thus states the result: "In the one suspended by the ears was to be seen a most complete state of anemia of the internal as well as the external parts of the cranium; in the other, suspended by the heels, a most intense hyperemia, or congestion of the same parts, and these opposite conditions in the vascularity of the brain induced solely by position and the consequent gravitation of blood." After these experiments, there can be no doubt as to the effect of position. Indeed this is evidenced daily by facts which are constantly occurring in disease.

I will next state my reasons for believing the fourth statement, "That the substance of the brain is like every other organ compressible, and capable of undergoing changes in bulk, independent of the blood it contains." I confess that I have as yet been unable to find anything like satisfactory reasons why the contrary of this has been assumed. I would ask, what are we to understand by a substance being incompressible? In answering this, I should say that we are unable, by any force, to compress such a substance into a less space than it naturally occupies, and if this be correct, I think those who carefully examine the brain in health and disease, cannot suppose it to be such a substance. I can find nothing in the ultimate composition of this organ which should render it incompressible; we find it to be made up of a number of fibres, cells, and tubes containing a semifluid matter, and many of the fibres are somewhat elastic, and wherever there is elasticity there is generally compressibility. I could bring forward, did the limit of this

paper permit me, the details of numerous inspections, where I have seen many ounces of blood and serum effused within the cranium, and of depressed portions of bone, causing severe pressure upon the brain, forcing it into a less space than natural, (although the cranial substance has beyond the shadow of doubt contained its normal quantity of blood), and very frequently much more, and as a consequence suspending the performance of its functions. If it were an incompressible substance this could not occur. What do we observe to occur after a portion of bone has been removed by the trephine. Cases are detailed, were surgeons have made pressure upon the brain through the opening, where, after it has advanced to a certain extent, coma was the consequence. It has also been observed, that the brain has a pulsatory motion communicated to it by the blood, during the contraction of the heart, being forced into the cranium, and by its being obstructed in its return by the veins during expiration. This may be observed through the open fontanel of the child. During these acts the brain rises, and is pressed against the unyielding cranial walls, and again falls; this shows that it occupies a greater space at one time than another.

The appearances observed in hypertrophy of the brain, show it to be both compressible and elastic. I extract the following from Dr. Watson's Lectures, where these facts are accurately described; he says, "When in these cases the skull is sawn through, the upper loose portion of bone starts up as if moved by a spring, and the edges of the bone remain widely apart." Laennec also, in Corvisart's Journal states, that upon opening the bodies of persons whom he had thought affected with hydrocephalus, he had been surprised at finding a very small quantity only of fluid in the ventricles, while the convolutions on the surface of the brain were strangely flattened, proving that the central mass had undergone strong compression, which could only have arisen from its preternatural volume, and undue nutrition." Copland also speaks of the elasticity of the brain. How strikingly have we exhibited in these cases, both the compressibility and the elasticity of the central structure! Dr. Watson states, that the calvarium was lifted up as if by a spring, which spring, in truth, was the elasticity of the cerebral substance.

It appears to me, when reflecting upon these circumstances, that there can be little doubt as to this structure being in the fullest sense of the word compressible; also that there is in the normal state a certain amount of pressure exerted upon it, which is necessary to the performance of its normal functions, an increase or a diminition of which is productive of different forms of disease. This normal pressure appears to be communicated to it by the impulse of the blood sent to it during each contraction of the heart, and is altogether independent of that from the atmosphere. The cerebral structure being somewhat elastic, if this normal pressure be removed, there is a resiliency or expansion of it, which, if it go beyond a certain amount, is incompatible with the performance of its healthy functions; and this I believe to occur in cases of rapid abstraction of blood from the cranium, as a rapid bleeding. Here the heart's power being weakened, it ceases to propel the blood with the requisite amount of force, and the consequence is a diminution of the normal pressure on the brain, followed by resiliency of the cerebral substance and temporary suspension of its functions, which are readily restored by favouring the advance of blood to the brain, and thus restoring the pressure. This is the explanation I should offer of syncope and similar ailments.

Having now very briefly endeavoured to show from facts and experiments that the four statements with which I started are correct, I will very cursorily glance at the bearing of these upon some points connected with the diseases of these parts.

Even those authors whose views I have been combating have been constantly in the habit of speaking of an increased and diminished quantity of blood in the brain; and I think that after the cases which I have detailed there can be little, if any, doubt that either of these two conditions may occur, and that most circumstances which favour the determination of blood to other internal organs will have a similar effect upon the brain. It is highly important to be fully aware of the fact that we may have an increased quantity of blood or fluid in the cranium at any time, because owing to the brain being inclosed in an unyielding bony case, there is not the same allowance for the expansion of this organ as in the other viscera, by which the effects of this pressure might be obviated, and, therefore, the cerebral structure is compressed, and fatal consequences may be the result. This excessive quantity of blood may be either of a venous, or an arterial character, or it may be both, and may occur without the slightest rupture of vessel, being in such quantity as to suspend (through pressure combined with the effect of venous blood on the brain, although I think the effects of this latter cause have been greatly exaggerated) the functions of the brain, causing rapid death. This occurred in some of the cases which I have detailed. It appears, also, very evident that we may have the different states of active and passive congestion of this organ, which are well known to occur in most of the other viscera, and it appears to me that many anomalous cerebral symptoms, may be dependent upon one of these forms of congestion. These symptoms often very closely simulate those of inflammation of those parts, and when we remember how closely active congestion of the other viscera also simulates the symptoms of inflammation in the same parts, this appears the more clear. Active congestion of the meninges of the brain is often found in those cases of delirium tremens which terminate fatally, the pia mater being minutely injected with bright red blood, without any of the products of inflammation. Similar appearances I have seen in some cases where, after severe concussion of the brain, symptoms verging on compression appeared, and terminated fatally in a few hours; the only morbid appearance being the minute injection of the vessels with bright red blood. Abercrombie describes a number of cases where, after death, he found similar appearances; and these cases, he stated, are attended with peculiar symptoms, which he describes very graphically. There are many cases of what are called hysterical affections of the brain, where the symptoms so closely resemble those of inflammation that it is impossible to say whether inflammation exists or not. I have myself seen such cases, and have seen very talented physicians unable to determine the point. Now I believe these cases to depend upon congestion of the brain or its meninges. It appears to me very probable that in many of those derangements of the nervous system, which appear in hysteria, chorea, and other similar ailments, there must be in many cases some derangement in the circulation through the part, which at times borders very closely on inflammation: and this I should apply equally to the brain. To go into the symptoms which will arise from these different states of the circulation would require much more space than the limits of this paper allow. If the brain be liable, as I believe it is, to become congested from the influence of similar causes to those causing congestion of the other viscera, we are enabled thus to explain the occurrence of cerebral symptoms in various states which otherwise appear obscure; such, for instance, as the fatal coma produced by intense cold, noticed by Dr. Solander and others; here we have the blood driven from the surface, and the internal viscera considerably congested, in which the brain participates. It is to a similar cause, I believe, that the greater prevalence of apoplexy in old people, during very cold weather, is owing; for it is stated by Dr. Heberden, that "the number of deaths by palsies and apoplexy in this country is always greatest in winter," the cerebral diseases of the aged being one of the most prolific sources of their death in winter.

It has been shown that the brain may be drained of its blood, almost to any extent, by general bleeding; an anemic condition of this organ is not an unfrequent occurrence, and gives rise to various anomalous symptoms, dependent, I believe, upon two causes; first, upon diminished pressure upon it, by which its structure is allowed to expand, in consequence of its own elasticity. This explanation of diminished pressure will apply more particularly to syncope, dependent upon violent mental emotion or other similar causes, where, through the medium of the nervous system, the action of the heart is suspended for a time, and the impulse communicated from it to the blood in the cranium ceases, and therefore the pressure is diminished. The second cause is, that the brain, requiring a certain amount of arterial blood, in order that it may be enabled to continue in the performance of its normal functions, ceases to do so whenever that supply is not afforded, or does so but imperfectly. The circulation of venous blood, or its collection in the brain in passive congestion, gives rise to a particular set of symptoms, characterised by lethargy, and an approach to coma, but I do not believe that it is capable of giving rise to any rapidly fatal disease; but when combined with pressure to a considerable extent, very rapid death is the result, as in the case of simple apoplexy detailed by Dr. Francis. If the pressure be increased beyond a certain amount, as this organ is compressible, its functions will be suspended; and an increase of pressure may result from the blood being sent by the heart with so much force, or in such quantity, to the cranial cavity as to compress it; but it appears to me, whatever be the propulsive force of the heart, however greatly it may be increased, that it cannot compress the brain unless there be an increased quantity of blood within the skull at the time, or unless there be some other fluid, as serum, or any other substance encroaching more than usually upon this cavity. Thus we have explained the frequent association of hypertrophy of the left ventricle with attacks of apoplexy; also the frequent mistakes which have arisen in diagnosis, where heart affections have been mistaken for threatening apoplexy, to symptoms of which they may give rise. This increase of pressure is partly obviated or guarded against, by the tortuous course of the carotid arteries, thus checking the force of the blood; also by the cerebro-spinal fluid in some measure, for if there be much of this serum in the cranium at the time the increase of blood is sent it will first displace a portion of this, forcing it into the spinal canal; but the impulse containing it will next compress the brain.

This varying amount of pressure is used by Dr. Burrows, very correctly, as an explanation of the periodical attacks of some organic cerebral diseases, as epilepsy, the attacks being produced frequently by some circumstance causing an increase in the heart's action, and therefore in the vascularity and pressure on the cerebral substance.

From these statements it appears evident, that in cerebral diseases where there are symptoms of an increased quantity of blood in the brain, we shall give relief by all remedies likely to diminish the force of the heart's action, and by bleeding we can undoubtedly draw blood directly from the brain.

Hernia cerebri affords a striking example of the elasticity of the cerebral structure.

The subjects which I have been considering are very important, and will admit of a much more extended inquiry than the limits of a short paper like the present will allow of.

A PRIZE ESSAY ON PURULENT ABSORPTION.

Communicated to the Medical Times

By THOMAS OTTREY RAYNER, M.D., F.S.A.

(Continued from p. 109.)

The experiments I have detailed are imperfect; because, in the first, the matter injected was not nearly of the same consistence as pus; in the second, the dog survived too short a time to allow any marked effects to develope themselves: nevertheless, their results, together with the other considerations I have mentioned, justify the conclusion that the irritation produced in pus if merely mechanical, is, at least, of a very violent kind; and a strong opinion that in many cases, pus in, contact with living tissues, excites inflammation, having a specific tendency to terminate in the effusion of more pus. The question in its various bearings is one of great interest, and deserves special investigation, of which I hope one day to make it the subject.

We have seen, from the cases and experiments which I have cited in different parts of this essay, that conse-

cutive abscesses show a marked preference for certain organs and textures, viz., the lungs, the liver, and the joints, and afterwards in order of frequency for the spleen and the muscles. How are these facts to be explained?

When we consider that all the blood of the system, and consequently, all matters mingled with that blood, must necessarily in each round of the circulation, pass through the lungs; that a very large proportion of the blood passes equally often through the liver, and, moreover, that from the peculiar manner in which this organ receives its blood, and from the size and multitude of its capillaries, the circulation through it is very slow, the solution of the question, as far as it regards these two organs, becomes obvious. The experiments of Cruveilhier of injecting mercury into the vein, confirm this view here indicated; for, when thrown into the general venous system, the greater part of it was always found scattered through the lungs; but when into the portal system by means of a knuckle of intestine drawn through an incision in the abdomen, it was found equally disseminated through the substance of the liver. It is no objection to the inference deducible from these facts, that the pus supplied by phlebitis of a vein that empties itself into the general system, and is therefore carried first to the lungs, frequently causes abscesses of the liver also, because Cruveilhier found that, in some of his experiments, many of the mercurial globules were carried *through* the lungs, and were afterwards arrested at different points of their passage through the general system. An observation made by Andral (Essai d'Hem. Path.) also bears upon this point; in a case of disseminated abscesses follow ing a large psoas abscess, he found upon examination with the microscope, that the blood of both ventricles of the heart contained pus globules; but that they were much more numerous in the right ventricles than in the left.

It has also been found, by examination of numerous cases in which phlebitis of some of the veins of the portal system has been the cause of death, that abscesses in the liver were the only consecutive lesions produced. A case of this kind is reported by Cruveilhier, in which such abscesses followed violent and repeated efforts to reduce a prolapsus ani; and another has lately been mentioned to me by Mr. Partridge, in which they were caused by the operation for fistula in ano. The lungs and liver therefore appear to act as filters, retaining a large number of the pus globules during their passage through them. The liver appears to accomplish this more completely than the lung, on account, probably, of the less force of the circulation through it, and the complicated nature of its capillary network. That in consequence of the large quantity of blood which passes through them, more pus corpuscles are arrested in these than in any other organs; the necessary result of which is, that they become the most frequent seats of consecutive abscesses. But joints, the spleen, and the muscles suffer in the next degree of frequency. Can we account for this? A knowledge of the anatomical peculiarities of these organs will I think furnish the explanation.

The recent researches of Mr. Toynbee, on non-vascular animal tissues, tend to prove that these tissues, the chief of which is cartilage, are nourished by the exudation of the nutrient liquor sanguinis from the vessels in their vicinity, which in consequence, the venous capillaries especially, are very numerous and large; those of the bone in immediate contact with the articular lamella, form dilatations capable of holding a large quantity of blood, which therefore circulates very slowly through them; those of the synovial membrane, and the areolar tissue in its vicinity, serve the same purpose, and accordingly exhibit similar peculiarities. It is evident from this statement, that if the views concerning the primary seat of the inflammation caused by pus, expressed in a former part of this paper, be correct, that these large sinuses, from the slowness of the circulation through them and the consequent accumulation of the pus corpuscles within them, must be very liable to become inflamed. The bones forming a suppurated joint must also in most cases be purulent in their interior; but I have never met with a case in which this point has been examined into. Such an examination would be very interesting; and should the result I anticipate be established, it would afford a strong confirmation. It is no valid objection to this view that the eye does not often become the seat of an abscess consecutive to ordinary phlebitis, because, though the vessels which nourish the extra vascular tissues of this organ are numerous, and some of them large, they do not exhibit the remarkable ampullæ formed by the veins which supply cartilage. In puerperal fever, a disease very analogous to phlebitis, which indeed constitutes the principal lesion in many of its forms, the eye-balls very frequently suppurate. We may account for the frequency of consecutive abscess in the substance of muscles in a similar manner; the vessels supplying it are very numerous, and two large veins accompany each artery to within one or two gradations of the capillaries themselves. The great vascularity of the spleen indicates the reason why it so often becomes affected.

But can we account in any way for the concentration of the inflammation in patches, so that circumscribed abscesses always result? The question is a very difficult one; the following, however, appears to me a probable answer.

Pus mingled with the circulating blood, must, when carried to the lungs, be diffused pretty equally throughout those organs; but, nevertheless, it is easy to conceive that a greater number of corpuscles may be carried to one or two capillary veins together, than to others; and consequently the disturbance of the circulation in them would be more complete than in their neighbours.

According to recent observers the first stage of inflammation consists in enlargement of the vessels in which it takes place, and consequent slower motion of the blood within them; just as we see in a mountain river, which at one part contracts itself into a rapid stream, at another deepens and widens into a pool, in which the current is very slow. The blood circulating therefore more slowly in such vessels, the pus globules would accumulate in them more and more at each round of the circulation, and inflammation would be thus determined in such spots, while the rapidity of the circulation through the surrounding vessels would be increased, and the chance of pus corpuscles being arrested in their diminished suppuration in one joint rather than another in different cases, must be determined by similar accidental circumstances.

I am quite unable at present to account for the lower lobes of the lungs being always more extensively affected than the upper ones, or for the preference which disseminated abscesses exhibit for the surface of these organs. A similar preference for the surface being shown in the liver, also, indicates that it depends principally on some peculiarity in the mechanism of the circulation. In the early part of this essay, I endeavoured to prove that in all the cases in which disseminated abscess following a primary lesion either was actually found to be, or else from its nature and situation was very likely to be, complicated with purulent phlebitis. It would appear from this, that phlebitis is the only disease in which infection of the blood by pus in quantities sufficient to cause consecutive abscesses, takes place. Some pathologists, however, have recorded the opinion that pus globules exist in the blood in a number of diseases. Mr. Gulliver, for instance, in a paper published in the *Philosophical Magazine*, Sept. 1838, announced that he had discovered with the microscope, pus globules in considerable numbers, in the blood of patients labouring under erysipelas, small pox, consumption, hectic from chronic abscesses, &c.; Mr. Lane, in a letter to the *Medical Gazette*, shortly afterwards, confirmed this statement; and I find that Andral, in his recent *Essai d'Hem. Path*, also says that he has seen pus globules in the blood in similar diseases, marked by characters so decided as to admit of no doubt about their nature. Now, these statements would, if true, go far to invalidate the theory which it has been my object in this essay to establish, because we do not find disseminated abscesses common in such diseases. I believe them, however, to be erroneous, for the following reasons:—

1. Because, in all inflammatory states of the system the lymph, or colourless corpuscles of the blood, have been found to increase greatly in number, and to become larger than those observed in the healthy state; in this condition they have so much the appearance of pus corpuscles, that it is almost impossible to distinguish one from the other. With the kind assistance of Mr. Bowman, I have examined under his microscope various specimens of blood, taken from patients suffering from several of the diseases mentioned by Mr. Gulliver. The following are a few of the results.—

1. Blood taken from the right ventricle of a dog, which had died from the injection of pus into the veins. Examination 18 hours p.m. Lymph globules very abundant.

2. Blood taken after death from the arm of a man who had died of sweeps cancer. Many lymph globules, with small granules, like those found in pus.

3. Blood from a vein in the back of a patient, with vomicæ in the lungs. Lymph globules more abundant than natural.

4. Blood from child with lumbar abscess. Rather more lymph globules than healthy blood.

5. Blood from an erysipelatous foot. The same result. The lymph globules observed in many such instances presented no characters sufficient to distinguish them with precision from the pus corpuscles contained in the blood in the first instance mentioned.

2. The recent researches of Mr. Addison, and more especially those of Professor Gerber, tend to show, that reparation is effected by means of these lymph or exudation corpuscles, which are thrown out upon an injured surface, and become organised in the form of the particular tissue to be repaired; that when inflammation was high, these are produced in too great abundance, that the supernumerary ones apparently die, and are thrown off from the inflamed surface in the form of pus corpuscles; that this result never takes place in an internal organ till inflammation has gone so far as to produce disorganisation, and that it is no more possible for pus produced in such situations to get into the circulation, than it is for pus thrown out upon an external surface to find its way unaltered into the blood.

I conclude, therefore, that the corpuscles seen by Gulliver, Lane, and Andral, were lymph corpuscles, and that pus in quantities sufficient to cause disseminated abscesses never enters the circulation, except in cases complicated by phlebitis.

It is no objection to this conclusion that disseminated abscesses have been found, without any phlebitis being detected. 1. Because the examination is incomplete, and therefore invalid, unless all the large veins, as well as the interior of the bones, are inspected. 2. Because the local appearances of a phlebitis, the pus from which has caused disseminated abscesses may disappear before the death of the patient from the latter lesion.

By some it has been objected to the theory I have endeavoured to sustain, that we every day see large abscesses disappear by absorption of the pus they contain into the general system, yet no disseminated deposits follow; but the objection betrays ignorance of the known laws of physiology, which point out the possibility of the absorption of substances in solution only; indeed it is absurd to suppose that a solid body like the pus corpuscle can pass unaltered through the equally solid walls of the absorbent vessel. That pus is often absorbed, is true; but before it can be so, the pus corpuscles must undergo some change, probably solution, after which it is taken up, and then excreted by the proper emunctories. Sometimes it is left behind in the form of cheesy matter.

Suppuration in the lymphatics seldom or never gives rise to consecutive abscesses, because the matter is arrested in the lymphatic glands to which it is necessarily first consigned; these appear to act as filters to the pus, and to prevent the solid parts of it from passing into the circulation.

The question has been suggested, Are any others of the products of inflammation, besides pus, capable of causing consecutive abscesses? The only experiment that I am aware of, bearing upon this point, is one performed by Majendie, who caused consecutive abscesses in the joints of a dog, by injecting into its veins ten ounces of the serum of the blood of another dog. It would seem, therefore, that serum and flakes of lymph probably, if carried into the circulation in large quantities, may cause such disturbance in the capillaries as to terminate in suppuration. But considering the readiness with which effused serum is absorbed, the large quantity necessary to produce the effect, and the fact that when a sufficient examination has been made, pus has almost always been found the exciting cause in the human subject, I imagine that the production of abscesses by any other means, must, in nature, be very rare.

(To be continued.)

HOSPITAL REPORTS.

MEDICAL TIMES PRIZE REPORTS.

SECOND SERIES.

Reported by THOMAS FRANCIS I'ANSON, of St. George's Hospital.

SURGICAL CASES.

CASE V.

Case of Fracture of the Base of the Skull.

John Smith, aged twenty-five, bricklayer, admitted by Mr. Cutler, 1844, Dec. 30, 10 A.M. Pulse small, weak, and laboured; action of heart feeble; trunk covered with a cold, clammy perspiration; extremities cold; breathing stertorous; features collapsed; pupils dilated, but capable of contraction on the application of light. There was complete insensibility to external impressions, with the exception of the above symptom. Blood oozed rather freely from the left ear and nostril. He had also sustained a lacerated wound over the right frontal protuberance; slightly denuding the bone.

His companions state that he had just fallen a distance of nearly sixty feet, from a scaffold to the ground; that when picked up he was found to be insensible, and was immediately brought to the hospital.

Warmth was applied to the epigastrium and extremities; and his head and chest were slightly elevated.

11 A.M. There is now considerable ecchymosis of both eyelids, with strabismus of the right eye and protrusion of the left, under the conjunctiva of which a considerable quantity of blood is effused. He still continues insensible, with stertorous breathing; has been sick several times; pulse 82, and of good volume.

Mitte Sanguinis ad ℥ix.

1 P.M. Has been again sick, and is now able to answer in monosyllables when spoken to in a loud tone; pulse 120, soft, and of less volume.

Calomel, gr. v., statim sum.

3 P.M. He remains in a drowsy condition, but will speak on being questioned; pulse 124, soft, and compressible; strabismus of the right eye not so great; bleeding from the ear still going on.

5 P.M. Strabismus disappearing; bleeding from the ear less; breathing more natural; still continues drowsy; pulse 108, fuller and harder.

M. S. ad ℥viij.

31st. During the night there has been very little stertor; the breathing is now quite natural, and the pulse soft and compressible; has several times vomited bilious matter. He appears more conscious; moans frequently, and lifts his hand to his head; he will also put out his tongue when requested; strabismus is now quite gone; bowels have not been acted upon.

Head to be shaved, and cold lotion applied. Haust. Sennæ, ℥iss. statim.

Jan. 1, 1845. Has slept several times during the night; bowels have been well opened; slight oozing from the ear still continuing. He is now quite sensible, and complains of severe pain on the left side of the head; pulse 88, rather hard.

Calomel, gr. ij. Opii. gr. ¼ 4 ta quâque horâ. Fever diet.

2. Has passed a good night; appears cheerful this morning; bowels open; tongue furred, but moist; pulse 90, softer than yesterday; still complains of great pain on the left side of the head; healthy suppuration is established in the wound on the forehead. Perst. in remed.

3. Pain in head much better; pulse 84, easily compressible; scalp cool; bowels open; no thirst; has an appetite; Perst. in rem.; beef tea one pint.

4. During the night he has been much troubled with diarrhœa, which was stopped by a rhubarb and laudanum draught; and the administration of the calomel has been discontinued.

The gums are now beginning to be affected, and the pain on the left side of the head is much better. He complains, however, of more pain in the wound, which is not looking quite so healthy.

6. Wound looking more healthy; no tenderness around it; bowels rather confined; pain in the head rather worse; pulse 84, harder than usual, but it is ascertained that he has been taking too much food. Haust. sennæ ℥iss. statim.

8. Pulse 72, soft; pain in head diminishing; tongue moist; bowels open; wound looking more healthy; appetite good. Broth diet.

10. Pulse 70, fuller, but not at all jerking; wound healthy; feels stronger.

13. A little serous discharge is now appearing at the left ear; pain in head no worse; tongue moist; bowels open; wound granulating, appetite good.

15. Says that last night when observing the flame of a candle, it appeared double to him when he looked at it with both eyes at the same time; but when he closed one eye, he could see distinctly with the other.

20. Continues to improve in strength, but still complains of his head, which he says has not an acute pain, but a confused aching, as if something were pressing it. To get up for an hour daily.

25. The pain in the head does not leave him, but his skin is quite cool, and pulse natural. Sp. Ammon. C. ʒ ss. Tinct. Calumb. ʒ j. Mist. Camph. ℥iss. bis die. Half ordinary diet.

28. Pain in head much relieved. Perst.

30. Pulse quick; tongue foul; bowels confined; pain in head worse. Calomel gr. iij. statim. Haust. Sennæ ℥iss. postea.

Feb. 1. Has now very little pain in the head; feels himself much stronger. Ordinary diet.

6. Continues improving. He has found that the skin of the left cheek has not so much feeling in it as before the accident; and he has in a great measure lost the power of using the muscles of that side of the face.

8. Has left the hospital convalescent.

REMARKS.

This is a case of supposed fracture of the basis of the skull. Recoveries from them, as Sir B. Brodie remarks (Med. Chir. Trans. vol. xiv., p. 326) are comparatively rare, not because the fracture is in itself more dangerous than fracture elsewhere, but because it is generally complicated with extensive injury to other and more important parts. It is rather a curious circumstance, that there was in the hospital at the same time another case under Mr. Keate, in which all the symptoms of this injury were present; but the patient was sufficiently well to leave the hospital in a few weeks.

We could get no distinct history as to the manner in which our patient fell to the ground; certainly he could not have fallen on his head, for the force acquired in such a descent would have been sufficient to have crushed the cranium; he might have fallen on a plank in his way down, or he might have alighted on his feet, or trunk, which being thus suddenly rendered motionless, while the head was still in projectile motion, the whole force of the fall was immediately communicated up the spinal column to the cranium, the base of which being the weakest and most irregular part of that cavity, gave way accordingly.

The first effect of the injury was insensibility, from the violence of the shock to the brain. Indeed, fractures of the base of the skull may be sometimes suddenly fatal—without the occurrence of extravasation—from the commotion in the medulla oblongata occasioning disturbance to the respiratory functions.

It is difficult to understand many of the effects of injuries to the brain. Some cases may be so severe as to occasion instant death, and on examining the brain no appreciable lesion can be discovered. In others there is good evidence that the brain has been penetrated, yet very slight symptoms have followed. But no doubt lesions often exist which we cannot discover; for as we cannot trace the delicate ultimate structure of the brain, it is evident that the same may be altered without our detecting it. Again, parts of the upper and anterior portions of the brain are frequently injured without serious mischief following, when the slightest injury to its base, or its posterior lobes, is often quickly fatal.

In the present case it was difficult to distinguish between the symptoms of concussion and those of compression. Probably, at first, it was pure concussion, but compression must have taken place very soon after. He was insensible immediately on receiving the shock, which generally happens in concussion; in compression this generally, but not always, comes on after some time has elapsed; had there been an intermission of the insensibility, the first part would have been set down to concussion, the second to compression. Sickness is generally attendant on concussion; it is a favourable symptom, showing that the nervous system is being restored. The pupils were sensible to the stimulus of a strong light; in compression, the pupils are insensible; but much dependence cannot be placed on the state of the pupils, as sometimes one may contract, the other dilate; or both may contract on the application of light. Stertor is generally an attendant on compression; but I presume that in this case, as in many others, the symptoms were so blended that it was impossible to draw the line of demarcation between them.

We must not suppose that the pressure was caused by bone, as there is seldom displacement of it in this kind of fracture, but rather to blood extravasated from some ruptured vessel. Of course, it is only conjecture as to what part was fractured, but the most usual course of the disunion is across the petrous portion of the temporal bone; thus causing rupture of the lateral sinus, part of the blood from which would escape by the external ear, and part would remain at the base of the brain, giving rise to the symptoms of compression. Perhaps there was also fracture of the floor of the orbit, causing rupture of some of its vessels; the blood from which becoming effused produced the protrusion of the left eye; or it might, perhaps, have been caused by some of the blood from the lateral sinus making its way into the orbit. There must have been pressure on the abducens nerve, supplying the external rectus muscle of the eye, so as to cause the strabismus.

The bloody chemosis also must have been caused by rupture of the conjunctival vessels.

The pain in the head, of which he complained so long, I attribute principally to the clot of blood, which of course required time for its absorption, and as it got less the pain also diminished; but no doubt, in the first instance, it was greatly increased by the concussion.

The serous discharge which appeared at the ear some days after the first symptoms had ceased, is almost constantly observed after fracture of the base of the skull, and is generally supposed to come from the arachnoid membrane.

With respect to the numbness in the cheek; there was probably some pressure of blood on the cutaneous branches of the superior maxillary nerve; and perhaps also some of the branches of the portio dura were injured.

The diagnosis of these cases is necessarily uncertain; but when bleeding from the nose, mouth, or ear follows an injury of the head, and has not been occasioned by a direct blow on those parts; or when ecchymosis takes place in the eyebrow after such an accident, though the part itself has not been immediately struck, these are important considerations, corroborating the suspicion of there being fracture of the base of the skull, implicating the petrous portion of the temporal bone, or roof of the orbit.

The *treatment* consisted, in the first place, not in bleeding, or giving internal stimulants, as in the vulgar opinion, for the first would have destroyed the feeble action of the heart, and the second would have rendered the liability to inflammation greater; but of warmth applied to the epigastrium and extremities; this equalises the circulation without producing congestion of any organ, and unless the collapse be very great, we need never be in a hurry to arouse the patient from it; indeed the premature occurrence of reaction may prove very calamitous, by favouring the effusion of blood. His head was slightly elevated, so as to retard the too violent influx of blood, as the collapse went off, and thus prevent the effusion of blood, or coagulation around the vessel of that already effused.

Bleeding is generally necessary to control the reaction, and prevent subsequent inflammation; perhaps in one case one small bleeding may be sufficient, while in another 250 ounces may have be withdrawn. In our present patient blood was drawn as soon as the pulse became full, and repeated when it again increased in volume. In fact, the tone of the pulse, and not so much its frequency, is the criterion by which we must be guided. A calomel purge was also given, both to clear out the bowels and produce a further lowering effect. Calomel in large doses was then prescribed, and continued until its effects on the system were perceived: next to venesection, this is certainly the most efficient means of preventing, or stopping inflammation. A rigorous diet was enjoined, and was in fact very necessary, as a very slight deviation from it soon caused an increase of hardness in the pulse. As the symptoms of increased action left him, a more nourishing diet was cautiously allowed; and after some time a little tonic medicine to help to dispel the pain in his head, which appeared to linger from want of nervous energy.

There is danger of inflammation, either after the effects of concussion have wholly ceased, or it may appear gradually as they are going off. The patient will appear languid, more restless than usual, thirsty; then the pulse will be quick, and perhaps corded; the skin dry and hot; the eyes suffused; pain in the head, as if a tight band encircled it; face flushed. If the surface of the brain have been injured, the mental functions may be but moderately impaired; but if the deep structures have suffered, the mental powers may be more violently excited; there will be furious delirium; pu-

pils very much contracted ; pulse 120, and hard. As it goes off there will be stupor, and the pupils will become dilated. If pus forms, there may be rigors, perspirations, twitching of the muscles, perhaps twisting the neck to one side ; a sense of weight in the head, yellowness of the skin ; then paralysis and stupor may come on.

Desault has divided inflammation into two kinds — phlegmonous and bilious — depending greatly on the constitution and habits of the patient, and the seat of the injury. The first kind is acute, and happens when the substance of the brain is affected. There is with it great vascular excitement and high delirium. In the second, the meninges are the seat of the disorder ; there may be low muttering delirium ; the vascular excitement will be less, and there will appear to be more gastric derangement.

Inflammation may come on at any time after the receipt of the injury—from four hours to three weeks, but most frequently between the eighth and twelfth days ; but if the collapse have been long, the longer time will have to elapse before the patient has passed the danger of inflammation.

When there is furious delirium and quickened circulation, we must bleed largely, and then rapidly introduce calomel into the system. Sometimes, also, cold affusion on the head will instantly check the delirium. In the meningeal form, we must rely on calomel, and not bleed. When stupor comes on, as it is mostly from congestion in the veins, a blister to the nape of the neck, or volatile liniment to the scalp, may be useful.

Fracture is sometimes followed by hydrocephalus, especially in children. Here the inflammation must be of a different kind from that which forms lymph or pus. We may apply leeches and blisters, and give mercury.

Concussion may give rise to chronic disease, such as thickening of the membranes, or scrofulous or malignant tumours, perhaps arising from a particular kind of excitement of the capillaries of the brain ; it may show itself weeks, or even years, after the accident. There will be partial paralysis of one or other organ, with irritability, and perhaps convulsions ; but these will disappear and recur at intervals. The only treatment we can employ is to repress the circulation by moderation in diet, &c., without lowering, and also occasionally by counter-irritation.

Sometimes we may suspect inflammation when there is in fact a state of anæmia, or a deficiency in the circulation through the brain, which may be caused by a weak heart, or the absence of accustomed stimuli. There will be great pain often fixed to one part of the head, blindness, or deafness, and perhaps delirium. But if we look carefully into the symptoms, we shall find that the pulse often intermits, or varies in some way, and is softer than natural ; the tongue is more creamy and tremulous ; the manner hurried, but not excited ; the countenance heavy. The patient may also ask for stimulus, which he would hardly do if he were labouring under inflammation.

REVIEWS.

On the Injurious Effects of Mineral Poisons in the Practice of Medicine. By Horatio Prater, M.D. Fcp. 8vo. London. 1846. pp. 96.

Doctor Horatio Prater is no common man, at least he says so. That we may duly understand and appreciate this sublime fact, before entering upon a perusal of his book, he graciously signifies upon its title page his numerous achievements, and regular "down-easters" they are. He denominates, or dubs himself, "Discoverer of the Fusible Compound of Carbon and Silica" !!—we should uncommonly like to see this magical mixture—"of the peculiar agency of lime on the tonicity of muscular fibre ; of the permanent fluidity of the blood by a heat of 140 deg. ; of the acceleration of its coagulation by ammonia, carbonate of soda, &c. (at p. 94 he tells us *carbonate of soda tends to keep the blood fluid!*) ; of the cause of the coagulation of albumen by heat ; of the diffusive power of the gases ; and conjointly with Fizeau, of Mosers Images ; author of *Experimental Inquiries in Chemical Physiology, &c. &c. &c.*" What the three finishing *et ceteras* mean, we are not informed, but suppose them intended to symbolise discoveries too numerous to mention. Now, after having done so much, and shut out Brande, Graham, and others, it is a pity the doctor did not go a step further when he was at it, and take the safety lamp out of poor Davy's hands, knock old Watt off the steam-engine, and swear himself the originator of both.

Epictetus somewhere says, it is often good not to be over virtuous; the doctor seems to think it is of no use being over modest, and therefore to save other people the trouble, enunciates, *pomposo*, his own praise ; taking his cue from the people of Athens, who, "in their reply to Pericles, rightly took the credit of what they themselves had done, and directed *their* name to be inscribed on the temples they themselves had reared." (P. xii.) So we see that, after all, there is something classical in nicknames.

The work commences with an epitome of the system of Cornaro ; a system which very judiciously rewards its followers by starving them to death. In treating this subject, the doctor has fairly knocked his head against the *elixir vitæ*, and realised at a single effort of mind the dreams of alchemy. The foundation of his principle is that generous old rule which tells us, that "one good turn deserves another," he therefore proposes that children, lawfully begotten of their parents, should gratefully perform a reflex function upon them when antiquated, by begetting them over again—not in the ordinary way of course, but of transfusion. "The means now alluded to, are the transfusion of the blood of one of its *full-grown* and healthy offspring, back again to the old parent, at certain intervals, where the parent, as in Cornaro's case, seems on the verge of death from mere loss of vital power." (P. 17.) "If there be anything approaching to the character of an *elixir vitæ* in nature, it seems more reasonable to look for it in the blood of the adult and healthy offspring, than perhaps to any other source." (p. 18.) The fact may now be considered fairly settled, that people need not die unless they like, and the doctor may fairly add to his other titles, "Discoverer of the means for turning old folks into young ones." He has more love of fame than of money, he says (p. 12), or otherwise, if he were to patent the process, it would bring lots of "grist to the mill." He does not stop short, however, with the blood, as the material to manufacture people's lives with ; for the "used up," he tells us that "eggs and oysters, as evidently containing a *vital principle*, may be used as nutriment; for, from their exciting nature, they seem perhaps to impart a certain quantity of this to those who use them." (p. 19.) Byron says—

"Oysters and eggs are amatory food,"

and the doctor proves that there is something more than poetry in the assertion. We should very much like to know what would be the effect of the *vital principle* of an egg, or an oyster, upon an individual partaking of either of these said things for a long time together. Whether the one would cause a man to cackle, *post defecationem*, turn his nose into a comb, his ankle bones into spurs, his whiskers into wattles, or his hair into feathers ?—and especially whether it would cause him to *crow?*—in which case it would be a capital remedy for bashfulness. Whether the other would be likely to make one scaly, cold-blooded, selfish, alter one's sex, and the like ? These points, very important as items of natural history, we hope the doctor will attend to, and, if possible, get decided.

He propounds other two very significant questions, "Does the optic or frontal nerve of an animal *just killed*, laid on the upper eyelid, benefit amaurosis ?—or the spinal marrow of the same, laid or rubbed on the spine of a debilitated old man, give any additional strength ?" (p. 19.) This very much reminds us of "experiment in joke made science in earnest." But no doubt there is a good deal of matter of fact connected with this questioning. We have often wondered why the managers of elephants should have such long noses ? We now remember that these men are often in the habit of holding a close facial correspondence with the brutes they tutor, and that, as a trunk is nothing but a prolongation of a nose, thus one may have acquired something of a resemblance to the other by the magic influence of contact. Perhaps Bottom, the weaver, got his physiognomy altered by lying cheek by jowl with an ass. We should like to know whether a fool, by rubbing his head against a philosopher's, would get an increase of wisdom ?

At page 21 the doctor tumbles upon another discovery, namely, "that a difference in the arrangement of the atoms of matter, is perfectly equivalent to a difference in its original nature, a conclusion arrived at in my experimental inquiry into Liebig's views on fermentation." We really had fancied this elemental chemical fact had been discovered long before Dr. Prater had meddled with crucibles and retorts ; but he says not, and it is scarcely worth while to contradict him. He offers, however, a very important suggestion, founded thereon. It is that "silica might under certain treatment become nutritious. Silica in the form of jelly might be tried, mixed in proportions gradually increasing in young animals with milk, or in adult animals with their usual food." (p. 22.) Here, again, we seem to be on the verge of another discovery nearly equal to that of the elixir vitæ, viz : that if a man ask for bread, and you give him a stone, you are not starving him after all. A lump of jelled silica may some day be as acceptable to an empty stomach as a barm dumpling or a roast potato. Shakspere no doubt thought he was very poetical when he talked of "sermons in stones," but what is this compared to eating them ?

At page 24 the doctor tells us that "silica in the gelatinous state is differently arranged (if a *simple* substance can be so) from what it is as mere silica powder." Another discovery! Chemists have hitherto been stupid enough to fancy silica a compound, but the doctor enlightens them with the fact that it is a simple substance ! He proves that the siliceous food may be taken by cats with impunity. He gave a lot of it to a tabby, and analysed its fæces, which were for the most part in a very satisfactory state. In the final bulletin, the doctor says, "The cat, I am glad to say, has remained quite well, now three weeks after the experiment." (P. 93.) He experimented on another cat, and astonished it so much, that, in self defence, it was obliged to destroy itself. "I found, however," says the doctor, "after the cat had been made to eat bread and milk, with which sulphate of lead was mixed, for some days, that a decided palsy of the limbs took place to my dissatisfaction, and the poor animal, in a state of half delirium, committed a sort of suicide by jumping out of an open window." (P. 60.) A notion prevails amongst old women, that a cat always falls on its feet. Dr. Prater may gravely assure them that he has proved from experimental research, that the law of a cat's descent out of a window is not universal.

The book winds up with observations on training, quite equal to anything in Bell's Life, or Fistiana ; a panegyric on Morrison's pills ; recipes for liquors of longevity ; and some sublime speculations on mesmerism. We must not forget to mention that the doctor is a poet, and by no means a common one, as the following lines testify :

We know some love smoking—smoke half the day ;
To all our great smokers here then we say,—
Adopt this new plan, smoke too *all the night*
Your camphor cigar, which ne'er wanteth a light !
Thus by you, *in your life*, no worms will be fed
Quite enough to be eaten by them *when you're dead!*

We feel assured, after the specimens we have given of the author's talent, philosophical, chemical, logical, and literary, that our readers will conclude, as we do, that Dr. Horatio Prater is far above all praise of ours.

An Essay on the Wear and Tear of Human Life. By G. T. Hayden, M.B., &c. Dublin: Fannin and Co.

This is undoubtedly one of the curiosities of literature. Much that is curious is given in a style, if possible, more curious ; and with the whole there is a dash of cleverness and occasional good sense which gives the volume every groundwork necessary to complete the piquancy of its interest. Without attempting to criticise by unalterable laws an effusion evidently written without any knowledge or fear of them in the mind of the author, we shall give a few extracts, and leave our readers to pronounce their own sound judgment!—

"The *lymphatics* are the antagonists of the secreting arteries, for the former remove what the latter had deposited. This branch of the absorbent system takes up all the integrant parts of the body ; is the remover of the *old* material, while the lacteals are the carriers of but one fluid (chyle), and that is the *new* product. The lymphatics are, as J. Hunter justly described them, the architects or modellers of the system. It is by the action of these ever-busy agents, that the body is fashioned and preserved from infancy to manhood—from the miniature to the full length likeness—in the appropriate and due relative proportions of its individual parts to each other and to the whole. It is plain, that the particles just deposited must be absorbed (so as to afford a space), before the deposition of the new ; and in the case of progressive growth, the space left for the secretion of the substitute should be so moulded as to accurately admit a certain sized integrant particle, and no more. The material so absorbed is, in the next place, commingled with the chyle in the parent trunk—the thoracic duct—and then returned to the sanguiferous system, by which it had been originally produced, to be either ejected, or, perhaps, employed for some secondary purpose. Since this process is constantly going on, the absorption of old, and deposition of new material throughout the whole body—a period must arrive when it may be truly said, we are re-made—having none of the original integrant particles. The reformation is supposed to take place in about seven

years. We before alluded to this process in bone—*a fortiori*, if it goes on so rapidly in the hardest parts, how much more speedily must it progress in the soft and more vascular parts of the animal body. We shall endeavour to exemplify this matter by an instance of every-day occurrence. Let us take an individual who is plump and fat; suppose him to be seized with fever—confined to bed for a month or six weeks. He now rises thin, nay, emaciated. What is the explanation? It is this. His digestive apparatus had been incapacitated, during illness, for the formation of the nutritive chyle, to supply the wants of the system, by replenishing the blood. The lymphatics absorbed the store of nutriment laid up, namely, the fat, and threw it into the circulating system—precisely as occurs in the hybernating animals (bear, sloth, and swallow), during their dormant state. The skin that had been tense and smooth, owing to the full deposition of fat beneath its surface, previous to the fever, has now become lax, flabby, and wrinkled, because the subcutaneous adipose development no longer exists. It has been all absorption but no secretion. However, there is no breach of surface; the patient has lost fat and flesh, which loss has been caused by an *interstitial* absorption from the cellular substance that hath contained both; collapse is, therefore, the inevitable result. Returning health—country air—keen appetite—generous diet, soon afford an abundant supply of nutritious chyle to the blood, which, in its turn, furnishes to the secreting arteries, the rich vital current; the latter quickly reproduces the adipose substance. Voila! our 'fat friend,' soon reappears 'himself again!'

"In early life, this function is exceedingly energetic; for abundant and speedy supply is then required for the purposes of growth. In late life, an opposite condition obtains in relation to lacteal absorption, while that of the lymphatics (interstitial) appears to be increased (in relation to deposition), which is but too plainly manifested by the spare, attenuated, and wrinkled condition of old age. In manhood, absorption—more especially lacteal—stands as a man between these extremes; neither so active as in the former, nor so sluggish as in the latter period of existence. As the habits of man are generally considered more active than those of woman, the function of absorption is, consequently, proportionably increased in the former. In the sanguine and muscular temperaments the active condition of the functions of digestion, circulation, and locomotion renders the energetic development of absorption more necessary than in any other temperaments. Wet and damp countries, where the atmosphere is constantly loaded with moisture, and the body surcharged with fluids, must—from the principle already proved—be less favourable for absorption than an opposite condition of climate.

"Nutritive absorption goes on much more actively in winter than in summer, as digestion is then more energetic; and besides, the demand for supply is more urgent in the former than in the latter period, owing to a greater exercise of the muscular system during the cold season. It is obvious that those of active habits, and accustomed to laborious occupations, must have more of wear and tear—greater expenditure, than those of sedentary habits who eschew exercise, and "the sweat of the brow." We have seen that an individual lost daily during two hours' hard labour in a warm atmosphere so much as ten pounds of his weight, and that on being weighed at three, six, and nine months a difference of but one or two pounds only was observable in relation to his original weight. It is plain that, in this instance, nutritive absorption must have taken place to a similar extent in order to compensate the system for the large loss sustained by exhalation.

"With reference to *fruits*, I have to remark that, generally speaking, they are to be esteemed by the valetudinarian as difficult of digestion. We are not, however, to interdict them altogether, for some species, particularly during a warm season, prove grateful, refreshing, and wholesome; and indeed the fact of their being so abundantly supplied by nature at this period, joined with the instinctive desire we have for them, would argue strongly in favour of their use. We will generally find that the derangement produced is caused by an injudicious selection of fruit—an excess in its quantity, and the fact of its being eaten at an improper time. Melons and stone fruit, with the exception of the ripe peach, are to be esteemed indigestible—melon and all cold fruits, cucumbers, &c., [particularly so—if the dyspeptic *will* eat the former, the horrible and dangerous act should be perpetrated with a plentiful supply of pepper and salt. Apples and pears are less prone to fermentation than most fruits; those that are disposed to torpid bowels will often be benefited by the last mentioned. Strawberries, raspberries, gooseberries, and grapes will be found, if eaten in moderation, and when perfectly ripe, cooling, digestible, and aperient. The husks, seeds, and skins of all fruits should be carefully avoided. Black currants are considered very wholesome. Oranges are general favourites, and, when ripe, may be freely used—the pulp should not be swallowed—the juice of this fruit and water make a grateful drink. Apples sliced and boiled in water also make an agreeable beverage. An observation we have often made in reference to articles of diet, is peculiarly applicable in relation to fruits, 'if eaten with a decided liking, it is surprising how rarely they disagree with the stomach.' Acescent fruits are most prone to interfere with digestion. The different forms of jams, jellies, &c., are very indigestible, owing to the large quantity (equal parts) of sugar added to the fruit to preserve it. It is fortunate that we are not often required to request children to eat little (jam *satis*) of these preserves, for they generally associate the latter with physic, and hence are inclined to "throw both to the dogs." Dried fruits are also open to objections for the same reason that jams and jellies are interdicted. We have somewhere heard it, as an 'old say,' that 'fruit was as gold in the morning, as silver at noon, and as brass in the evening.' Paris says, 'The most proper period for indulgence in fruits appears to be in the morning and evening. On some occasions it may be taken with advantage at breakfast, or three hours before dinner, and it affords a light and agreeable repast if taken an hour before bed-time; but,' he judiciously adds, 'these regulations are to be influenced by circumstances which no general rule can possibly embrace.' It is therefore so necessary that the close and accurate observation of the valetudinarian *himself* shall constantly be directed to time, quality, and quantity, as the grand tripod upon which dietetics rest.

"Dr. Johnson observes that the wear and tear complaint is almost peculiar to England, and explains why it should predominate in London so much more than in Paris, because in London business is the almost only pleasure; in Paris, pleasure is the almost only business. In this respect Dublin may be said to hold a middle place—neither so busy as the former, nor so idle as the latter; hence its inhabitants, generally speaking, enjoy good health. If Pat had the prudence of John Bull, would eschew gentility, the besetting sin of Ireland, not ape his loftier and richer neighbours' habits, and consequently their expenditure, he would learn to live more contentedly and tranquilly in that state of life 'into which it had pleased God to call him.'

"My countrymen are too vain to be proud, while the Englishman is too proud to be vain; hence the former is always striving for that extrinsic, *nitor ultra vires*, to make his neighbours *stare;* the latter constantly working to produce intrinsic domestic *comforts* for himself and family.

"Are we to look for an explanation of this in organization, climate, soil, and its productions? A learned friend of ours attributes a vast deal of the developement, physical, moral, and intellectual, of the Irish, to—what do you think? You cannot guess!—you must give it up!' Well, then, '*Potato-diet* is the cause of all!'"

TO CORRESPONDENTS.

A Surgeon.—We see no illegality in the rules of the Benefit Club named. *The mode of appointing the Surgeon, however, is certainly objectionable.*

A Member *should address his letter to the Secretary of the Sydenham Society. Mr. Adams' translation is learned and clever; it has especial interest as the work of a general practitioner.*

A Subscriber *will, on reflection, see that we have no business with the tracts of the Society he mentions to us. The aims are useful; and though not opposed to ours, are yet beyond our province.*

Philo Medicus *is unnecessarily severe in his strictures on Mr. Battley's address to Medical Students.*

W. X. *is thanked for his extract from Tait, but we have no room for it.*

A Student *will find most of his remarks in Grainger's lecture on the Unhealthiness of Towns, and said with at least as much grace and force.*

Pharmaceuticus writes:—*It may not be known to the Pharmaceutical world generally that in the year 1686, an important work was dedicated to the Master, Wardens, cæterisque clariss. Societ. Pharmaceut. Lond. Sociis. Can you inform your readers what relation the young society is to the old one, or whether or not the Society in Bloomsbury Square is intended to supersede the venerable and ancient one so long known as the Pharmaceutical Society all over Europe?*

*** *The supercession does seem the avowed aim of the new Society. It may be added that the Apothecaries' Society has been always known to the Law and to the heads of the State as the Pharmaceutical Society.*

Mr. Thomas Yardley—*Anatomy cannot be properly learnt by plates; indeed in most cases they are worse than useless, as they give erroneous notions of the relations of parts.*

Mr. Ackland's *paper can only be inserted as an advertisement.*

G. G. *we fear is a hypochondriac. Why does he not call on the nearest medical man? his fears would then be set at rest at once and for ever.*

G. F. C. —*Let the subject rest for the present. The tether will soon be run out. We are obliged to our correspondent for his kind preference.*

Mr. Boyd's *Vapour Bath seems to be a simple and ingenious apparatus.*

Mr. Williams *will understand the point contended for more clearly after reading the conclusion of the paper alluded to.*

A Student *should ask the advice of the lecturer on Midwifery at the school he attends. Our correspondent can scarcely expect us to advise him where to attend Midwifery cases, when he does not even tell us whether or not he resides in London.*

Mr. Thomas Leithead.—*The worshipful Society of Apothecaries do not propose to prosecute duly licensed practitioners of any class. They still possess the power, however.*

We shall be happy to receive any communications from Mr. Davis. *The conclusion of our correspondent's letter alluding to* "damage," *is not quite clear to us.*

Mr. Close's *request shall be complied with. Unfortunately the manuscript had been mislaid.*

☞ *Subscribers in arrears since Midsummer are requested to communicate with our Publisher during the ensuing week.*

THE MEDICAL TIMES.

Saturday, July 25, 1846.

Ille profecto
Reddere personæ scit convenientia cuique.—*Horace.*

In our last article we "considered the relative importance, intellectually and educationally, of the clerical and the medical professions. The inference we drew, and we are not apprehensive of its truth being exceptionable, was, that not only are severer preparatory studies required of the candidate for medicine over and above what are required of the candidate for the pulpit, but that, in their subsequent professional exercises, more practical learning, and much more mental and bodily labour, are demanded of the physician, or surgeon, than of the parson. We conscientiously believe in the orthodoxy of our deduction; and are fully satisfied that, from any impartial tribunal, a similar judgment would be given. So much for the intellectual relation of the two parties.

As regards the *morale* of the two, it is difficult to speak openly, and not invidiously. Whilst we are utterly adverse to say anything to the disparagement of our ecclesiastical brethren, we are yet, in all justice, called upon to vindicate and maintain our own dignity. Believing, as we do, that we are often slandered and derided when we deserve no such stigma, it becomes us to assert our own character on those points whereon the public are apt to misjudge us.

To begin with college days. Will any man, competent to judge of the respective parties, venture to affirm, that better discipline, better general conduct, or better moral propriety, is characteristic of the student of divinity than of the student of medicine? We have no fear of any such opinion issuing from any source other than one incompetent to judge at all, or not honest enough to judge fairly. Medical students, all the world over, are targets for popular prejudice to fire at. They are accounted

fair game, and nobody hesitates to make a hit at them. An old superstition paints the devil with horns, and cloven feet, and a tail, sometimes dragging, and sometimes curled round his arm. At this moment, an anecdote bursts in upon our memory, and we cannot resist relating it.

It is said of Cuvier, that, one day walking where Æneas is said to have walked, a certain repulsive personage met him, and demanded of him worship. "No, I will not worship you," said Cuvier. "Yes, you must," said the horrible. "No, I shall not," replied the other. "Then," said the demon, "if you do not, I will eat you!" Cuvier eyed him deliberately, and instead of defying him, as no doubt he might have done, preferred falling back upon the natural history lessons of his mundane life, and said—"horns, and cloven feet—*graminivorous—you eat me—nonsense!*"

Perhaps the anecdote may be worthy of the episode it has caused; if so, we will proceed with the discourse we were entering upon concerning medical students. As we said, in conformity with popular prejudices, they are looked upon as something terrible—little short of awful, desperate, diabolical, or what else you will. Nobody, now-a-days, ever thinks of figuring in his mind's-eye a medical student, except in a pea-coat, with long hair and large buttons; thick shoes on his feet; a thick stick in his hand; a belcher tie round his throat; and a seedy white hat on his head. Added to these things, he should have a bull-dog following him sneakishly; a stealthy look-out for creditors when he's sober, and a devil-may-care swagger when he's drunk—the latter condition being generally in the ascendant. He should never be known to be without two or three street-door knockers in the poacher-like pockets of his coat; he should never be able to pay a tavern-bill when it's called for—and always be ready to fight the waiter, or anybody else, who may venture to dispute a reckoning with him. These, with a few other items, not necessary to enumerate, make up the medical student as the public regard him. But this is not all. Not only do the public picture him as they like, but they unhesitatingly visit him with all sorts of responsibilities. If an antiquated old lady, in a country village, lose her favourite tabby, or any *soi-disant* young lady be parted from her pet spaniel—who is the offender? Of course the apothecaries' young man—he is the thief—he has stolen the poor animal—no doubt for some cruel experiment; and, before next week, the only remnant may be a grinning skeleton! If any outrage be perpetrated in a large town, or in its neighbourhood, sure as fate the imputation rests upon a gang of medical students! If a public-house sign-board be fresh painted, or turned upside-down, or taken away altogether; if a stable-door be nailed up, or lifted from its hinges, or sent swimming into a horse-pond; if the pinfold-gate be broken down, and the hungry prisoners let loose; if the local decorum and decency be in anywise disregarded or defied, as in throwing down a cracker, or sending up a rocket; nailing up a watch-box, or knocking down a policeman; kicking over an apple-stall, or kissing a stray servant-maid;—poor medical students come in as the responsibilities for all. They are respectable men—they have got lots of money—they can afford the disgrace—fasten the offence upon them, whether they have committed it or not—the game is certain—they are sure to pay! So it is.

In capitals, and in places where medical education is rife, the students make most excellent game. Nothing popular, in fact, can be done without them. If a pop-bottle goes off in the gallery of the theatre, the author of the disturbance of course is a medical student; if any young gentleman in the pit, shout a stentorian "bravo," or "encore," or venture a hiss, or stand up, and with his hands in his pockets dare to wink his eye, or twink it, or even turn his eye at all, at the ladies in the boxes, forthwith he is nothing short of a medical student; if any man, not a horse-breaker, drive tandem through the streets, he can be none other than a medical student; if a hackney-coachman be squabbling with a passenger, upon whom he is endeavouring to impose, the aggrieved party is a medical student, and of course in the wrong; if any drunken boast be performing a hydrostatic feat in any public quarter, he is a medical student, and ought to be ashamed of himself; if a policeman be dragging a sinner along the street, with a crowd at his heels, the imprecations, yells, cat-calls, and curses, are at the medical student! Such are the sins perpetrated against us, and yet, without a murmur!

Nay, to such a pitch has the insult against us risen, that if a common thief, found with a tavern-can in his pocket, or a silver spoon, or anything else, neither too hot nor too heavy to carry away, be asked the peculiar questions usually pointed at men under such circumstances, he invariably precedes his answers by stating that he is a medical student. His name may be Smith, Jones, Rogers, or Robinson—no matter what—the patronymic is nothing—the calling is all—medical studentship is the business—and the responsibility is secure! No riot, no row, no outrage of any kind, not even a local street tumult, can occur in a place where medical students congregate, but instanter they are considered at the bottom of it all! Poor fellows! no matter what their *bonâ fide* sins; they have to bear the brunt of as many more as popular prejudice and absurdity choose to fasten upon them. Because they are accustomed to be witnesses of the ravages of diseases, and are used to see the evidences of death in its many phases, and under these painful circumstances betray no puny emotion, and exhibit no false-hearted regret—not being prepared, like Job Trotter, with a small clean pocket handkerchief, and a pair of weeping eyes, for every little mournful occasion—for the want of these things they are scouted as infidels, brutes, unfeeling creatures, non-naturals, and nobody knows what besides! If they exhibit tender-heartedness, they are hypocritical or foolish—if they converse, they are brutal! Do what they will, they are sinners, and nobody sympathises with them. They might be Irishmen, every man of them; for then, as Swift says, they would be cursed, in due form, accordingly.

Oh! to us, who have mingled right well amongst the ranks of students of every denomination, the injustice done to our order is gross enough. "The offence is rank," and deserves the reprobation of every honest man. Many have been the offences we have known the pale-faced, meek-eyed, sycophant, shrouded in his assumed sanctity of study, commit, and with an impunity which would have defied detection in any other man. We have watched at many a carousal, where the two classes we speak of have mingled together, and have each forgot the decencies of sobriety in due form; but the poor medical student, no more degraded, but much less plausible and morally pathetic in his degradation than his fellow-toper, got off with far smaller credit. When better means have failed, we have known a student of divinity sing a snatch of a psalm—or utter a maudlin sentimentality of some kind—or drop a tear of sympathy over some imaginary object of commiseration—and all to screen the evidences of his own disgrace! Such men have so many means of shelter in their keeping, that not only can they hide themselves therein to their own satisfaction, but effectually defy the public to find them out. The very sanctity of their calling is such as to raise them above suspicion. Impugn any man, be his offence as glaring as it may, and instantly you are liable for sacrilege! We have known students of divinity do openly, and with impunity, certain things whose committal would for ever have stamped the fate of a student of medicine. And why? Because, on the one hand, it is taken for granted that the impugned individual is engaged in a calling far above the liability to such enormities, how far soever the perpetration of them may seem to apply to him; and on the other, the partial sinner gets the credit of the whole offence, because no hypocrisy or cant on his part has shielded him from public opprobrium or suspicion. To enter into individual evidences would not consist with our sense of fairness; but we have not the slightest hesitation in saying, not only that medical students generally are the subjects of gross public prejudices, and have imputed to them offences wherewith they are in no wise chargeable; but that, if their brethren of the more sombre caste were criticised as keenly, they would be found one-half as daring, and ten times as secretly sinful.

THE NATIONAL INSTITUTE.

The steady increase of popularity which greets this importunity project is most gratifying: and the steady energy and deliberate zeal with which the Committee of the Association are advancing all its preparatory arrangements command universal praise. The approaching meeting, in which the decisive step is to be taken of definitely establishing the Institute, is looked forward to with no ordinary anxiety. It is the great event which is to decide for attained good or perpetuated evil the fortunes of the profession. We earnestly trust that our readers will omit no duty on their part which may tend to give the first National Institute the profession has yet voluntarily combined to erect, a fair and full chance of a good start and ultimate triumph. The Institute belongs to no collegiate clique or professional grade: it is the institute of the whole profession of the British Empire; and there is not one impolitic rule, bye-law, or condition to exclude from its comprehensive bosom any legitimate member of the kindred community. Membership will detract from no man's worth or standing: giving at once cohesion, respectability and power to the whole body, it will rather attach additional influence and standing to each component. But this portion of the subject is so well handled by by Mr. Herbert Barker, in a pamphlet recently published by him, that we shall prefer to address our readers in his language.

FIRST—TO THE MEMBERS OF THE NATIONAL ASSOCIATION.

The difficulties which surround the carrying out of a scheme of the magnitude and importance of the proposed National Institute are immense; and it is evident that the most cordial and persevering co-operation of most of the practitioners throughout the country, will be required to second the efforts of the committee of the association, in order that the scheme may be put into effective operation. In the words of the committee—'If they are not disposed to do so with zeal, and even with enthusiasm, or by some other means to maintain an effective organization, all amelioration of their condition is hopeless.'

A large annual sum will be required for the objects which have been referred to; yet, if from five to ten thousand general practitioners act so far in concert, as to subscribe a small sum each annually, a very large yearly income will be derived; it is desirable therefore that every member of the association should give in his adherence to the plan which has been proposed, and,

at the same time, intimate his readiness to assist in th pecuniary support of the institute, by naming a su which he will be willing to contribute to its funds.

Another indispensable requisite to the permanent e tablishment and efficient working of such an institutio is, that the utmost confidence be reposed in its execu tive council, and particularly in those upon whom th duty may be imposed of carrying the wishes of the pro fession into effect in the first instance. The conduc of the committee of the association through the mo trying and critical seasons of its existence would natu ally point to that body as the most fit to be entruste with the highly important duty of completing the p posed design. From their recent exhibitions of tal and zeal in the cause of the class which they represen the members of the association may continue most con fidently to repose their affairs in the hands of those gen tlemen, who will at all times be ready to give their m ture consideration to any suggestions which may l offered; and it must ever be borne in mind, that thei objects and interests are identical with those of th members at large. The wants and interests of th entire body are equally the wants and interests of th committee themselves.

The enrolled members of the National Institute wi be entitled to vote for the members of the council thus will be secured to them a council of their own elected by the majority, and, consequently, to thi council may safely be entrusted the election of the pr sident and vice-presidents, and the preparation of a cod of laws for the regulation of its affairs, *which will b subject to the approval of a general meeting of th members.*

Through the medium of a council so constituted every one in general practice may have a voice in th control of the affairs of the Institute; his position in a legislative or political point of view will thereby be con siderably improved; and the affairs of the class to which he belongs, must necessarily be most satisfac torily adjusted.

An appeal will be made to the members for contribu tions to the pages of the transactions, a general an hearty response to which cannot fail to be of grea utility.

The plan upon which the Library will be conducted will render it more generally available and useful to th profession than any other Library in existence; an the Museum, from its practical nature, will become a vast storehouse of pathology, and a collection, to which every member will be proud to present morbid speci mens from time to time, as he may have an opportunity of thus extending its usefulness. As an illustration of the enthusiasm with which the Institute is hailed by some, it may be mentioned that one gentleman has in timated that he is prepared to deposit at once, as a nucleus, a collection made by his own hands, of three thousand specimens in natural history.

As the members of the Association have already taken an effective part in the movement, it is only necessary to exhort them to complete what they have so auspiciously commenced. You have manifested, by your co-operation with so many of your brethren in the formation of a large Association, that at one time you considered a necessity existed for this combination; you have now an opportunity of assisting in carrying out far more extensive, more important, and nobler designs than have ever engaged the attention of any body of the profession. Only let that assistance be given with zeal and unanimity, and every object will be accomplished. With feelings of pride, you will shortly be able to point to a great and successful Insti tution, and at the same time enjoy the reflection that you share the honour of having reared so useful an edifice, and of having contributed to elevate the status of the profession to which you belong.

SECONDLY—TO THOSE WHO ARE NOT MEMBERS OF THE NATIONAL ASSOCIATION.

If the county of Bedford may be taken as an exam ple of the kingdom, the number coming under this head is but small, there being fewer than one-sixth of the general practitioners of that county who have not already joined the National Association.

Some have not joined it, from a hope that the Coun cil of the College of Surgeons would procure a supple mental Charter, by which the wrong which has been done to most of the members of that College would be redressed; but every appeal which has been made to the Council has been in vain; and since the ill timed and unhappy vindication of its proceedings by the last Hunterian Orator, the staunchest friends of the College must have been convinced that such alterations as would constitute it *the* College—the head and home of the general practitioners,—are hopeless and impracticable.

There are others who, having acquired an honourable independence, are content to enjoy their *otium cum dignitate*, manifesting by their supineness, an apparent indifference to the progress of medical affairs, and the success of any efforts directed to the prosperity of the profession at large. If these gentlemen cannot be induced to take an active and zealous part in the work, after the example of our venerable presi dent, who, although he has acquired a well earned reputation and an ample fortune, is devoting his energies, his time, as well as considerable pecuniary aid to the improvement of his class, they surely must have the welfare of the profession and public sufficiently at heart, to lend their *passive* assistance, by joining an Association with these objects in view.

Some think themselves too much engaged in their professional pursuits to be able to give the slightest consideration to any other subject, leaving everything relating to Medical Bills and Associations to their younger and less occupied brethren. Such conduct is directly opposed to that of the members of the Committee, who, although most extensively engaged in the practice of their profession, and not expecting to reap any *personal* advantages, have devoted much time and attention to the subjects which have come under their notice. This they have not done merely for a week or a month, but even daily for many months, with a disinterested zeal truly admirable and worthy of imitation. The transactions referred to form a monument of combined industry, well calculated to stimulate us to greater activity and energy.

Other members of our peaceful profession, with an antipathy to any movement having the least appearance of political agitation; and perhaps, having witnessed the rise and fall of numerous minor Associations, which have lacked the elements of perpetuity and usefulness, have refrained from giving their assent to the National Association on these grounds. They may be confidently assured that this Association has arisen solely from the emergency of the times, and the perilous position of their own class, and not from a spirit of factious opposition to existing laws and institutions. Their serious attention is invited to the proceedings of the Committee, as the most satisfactory refutation of the suspicion of interested faction or agitation.

Some, participating in the liberal political views of the day, and carrying a species of ultra-liberalism into medical politics, have denounced the proceedings of the Colleges, and of all protective medical Associations, proclaiming for "*free trade in Physic.*" The number of this class of objectors is very small, probably the smallest of any, but should these observations meet the eyes of such, let them reflect on the relative condition of the public and profession during the last thirty years, as compared with that condition *before* the passing of the Apothecaries' Act, and let them also maturely reflect on the consequences of unrestricted practice, in reference particularly to the poorer classes of the people, and to the status and respectability of the educated part of the profession. The medical man who can seriously avow these principles, as applicable to medical affairs, possesses but slight feeling of true humanity, and surely wants the *amour-propre* of his profession.

Lastly, to those who have so magnified a view of the difficulties in the way of attaining the objects aimed at as to remain neutral and inactive, we would observe, that there are no difficulties so great, but that they may be overcome by well-directed, and persevering efforts. In the National Association, a powerful combination is already formed to hand, which will be rendered still more effective by every accession to its numbers.

The same zeal and unanimity which organized that Association, and successfully parried the destructive blow with which the profession was menaced, will place the National Institute upon a firm footing; and the only question for these gentlemen to decide, is, whether they will remain mere lookers-on, until every obstacle shall have been thrown down, and a great College reared, of whose fostering aid they will then be glad to avail themselves; or whether they will participate with their brethren in the proud satisfaction of having contributed their share of influence towards its establishment, with all its accompanying advantages, both to the profession and the public.

"*Auxilia humilia firma consensus facit.*"

LABERIUS.

We will just add to these pertinent and forcible remarks that any gentleman wishing to join the new institute may send in his adhesion in a letter of this form:—

GENTLEMEN,—I beg to forward my replies to the following Questions:—

Are you willing to co operate in the formation of a National Institute of Medicine, Surgery, and Midwifery, upon the plan detailed in the accompanying Letter, by becoming a Member, and contributing towards its support?	
2. That the Committee may be enabled to estimate the sum at which the Annual Contribution for the support of the Institute should be fixed, what is your opinion as to the amount of such payment by the Metropolitan and Provincial Members respectively?	For Metropolitan Members? £. s. d.
	For Provincial Members? £. s. d.
3. At what period after the Date of his Qualification to Practise should a Member of the new Institute be eligible for a Seat in the Council?	Unlimited?
	5 yrs.?
	10 yrs.?
	15 yrs.?

I am,
Gentlemen,
Your obedient Servant,
Name ————
Residence ————
Qualification ————

To the Committee of the National Association of General Practitioners in Medicine, Surgery, and Midwifery,
294, Regent Street.

MISCELLANEOUS CORRESPONDENCE.

PRACTICAL REMARKS ON SOME POINTS OF TRICHOPATHY, AND THE CHEMICAL PATHOLOGY OF THE HUMAN HAIR, by THOMAS CATTELL, Esq., of Braunston, Northamptonshire, M.D., M.R.C.S.E.

(To the Editor of the Medical Times.)

SIR,—It is greatly to be hoped that Dr. Cattell is better versed in the principles and practice of medicine than, by his writings, he appears to be in the elements of chemistry; if he be not, the inhabitants of Braunston, or at least those of them who may patronise the doctor, must be more indebted to the *vis medicatrix naturæ*, than to the curative effects of art.

Thomas Cattell, Esq., M.D., M.R.S.C.E., condescends to edify the readers of *The Lancet* by writing on hair-dyes; and, considering that he is writing on a subject of which he knows nothing, I must confess he discourses most learnedly. Colouring and decolorising are too common-place terms, and, accordingly, he embellishes his lucubration with the euphonious compounds, *tricho-dyschroia*, *tricho-crosology*, &c., &c.!!! I much admire refined language when it is necessary for the exemplification of the subject; but when used only with the hope of mystifying, it is really as nauseous as it is unpardonable.

With a grand flourish of penny trumpets, commencing with *tricho-dyschroia*, the doctor gravely informs the profession of the bleaching property of gaseous chlorine!! As, however, this important fact is known to every washerwoman, we will take it for granted that the doctor is correct in his discovery. I also coincide with him in, and believe he deserves the thanks of the profession for his suggestion that "the constant use of a diet deficient in the elements of the hair *may* stand as the proximate cause of its change of colour!" Under the head *Tricho-crosology* Dr. Cattell presents us with seven formulæ for dying the hair. These he divides into the three several classes of *Plumaform*, *Steariform*, and *Chulosiform* dyes!

The Plumaform consists of oxide lead, 3oz.; carbonate lime, 2 oz., mixed with water, and applied to the hair enveloped in oil silk.

The second recipe is similar in its nature, carbonate being substituted in lieu of oxide of lead.

Of these two compounds all I have to say is, that neither will answer the purpose. The doctor must expel the carbonic acid, and then convert the resultant into a *hydrate*, before he can succeed in even tinting the hair with these remedies.

The *Steariform*, and three out of the four *Chulosiform* dyes are compounds so uniquely chemical, that I feel incompetent to comment upon them. I rest content with the simple remark, that the admixture of soap (I beg the Doctor's pardon—I mean, "*Sapo viridis*") with nitric acid and caustic, is a cut above my comprehension—profoundly hyper-chemical, and best let alone.

We now come to a recipe, which, to use the learned doctor's own words, "claims a decided preference over all those previously enumerated, which can produce injury to neither the hair, skin, nor brain, *and which possesses the advantage of communicating a beautiful colour and curling property to the hair!!!*"

Would any reasonable being believe that the com-

position which the Doctor thus eulogises possesses *none* of the properties asserted in the panegyric?—could any one credit that an M.D. and M.R.C.S. would so expose his ignorance as to avow himself the inventor of a compound which the veriest tyro in chemistry must see at a glance is nothing more than *glue and goulard!!*

The learned man thus directs us to make his aq. mirabilis:—

"Lead filings, 2 oz.

"Hartshorn shavings, 1 oz.

"Oxide lead, 6 dr.

"Camphor, 1 dr.

"Water, 1 lb. Boil for half an hour, and, *when fine*, pour off the supernatant liquor on diacetate of lead and rosemary leaves, of each one drachm. Again boil, and when sufficiently fine, pour off the supernatant liquor which constitutes the dye." Now the only soluble ingredients composing this hotch potch are the sugar of lead and the gelatine! Hartshorn shavings, according to Merat Guillot (Traite de Chim, vij. 643) consist of Phosphate of lime, 57·5; Soluble Cartilage (Gelatine and Chondrine) 27·0; Carbonate lime, 1·0, and water; and merely gives out by aqueous decoction gelatine to the menstruum, the carbonate and phosphate of lime being deposited; as is also the case with the oxide of lead and the lead filings, which are insoluble! The part the gelatine is intended to play I cannot divine, as it is well known to manifest so little tendency to unite with the metallic oxides. The doctor thinks the long boiling may increase the solubility of his oxide and facilitate the oxidation of his filings,—a result he evidently aims at, but he should recollect (if he ever knew) that the chances of this are lessened by the viscidity of the menstruum, and, in addition, are entirely prevented by the presence of the phosphate, 1-30·000 of that salt being sufficient.

But we are directed, *after the subsidence*, to pour off fine and again boil. This second boiling can only be intended to *volatilise* the camphor and destroy the aroma of the rosemary. Having effected this, we again decant the "supernatant liquor," which terminates the process, and to compensate us for our trouble, we shall possess a hydrate of gelatine (which, on cooling *solidifies*), mixed with diacetate of lead!!!—a good remedy, truly, "*for communicating a beautiful colour and curling property to the hair.*"

For "*Calvities* and *Alopecia* the doctor possesses remedies, *uniformly* efficacious." The kind, humane man renders palpable his possession of Christian blood by giving us, without a fee, directions how to prepare the famous specific: "Rosemary, maiden hair, Southern wood, myrtle berries, and hazel bark, of each 3oz. These are to be incinerated, and with the incinerated mass make a strong ley, with which to wash the hair every day!" This roundabout way of making salt of tartar is equalled only by the Frenchman's remedy for the destruction of fleas.

The doctor terminates the account of his brilliant discoveries by "trusting that professional men will for the future, and *not nostrum mongers*, take charge of the diseases and affections of the hair." I hope they may; but upon my honour I should be extremely sorry to trust my capillary growth to the treatment of Dr. Cattell. With all due deference for the seven initials he attaches to his sponsorial patronymic, I should still prefer placing my canister under the hands of the Rowlands, Kirbys, the Rosses, and Bernards et id genus omne. I hope the doctor in his next communication will give us less Greek, but *more* sense than characterises his paper, and that its editor will no longer insult the few remaining readers of *The Lancet* by admitting into its columns the ravings of every madman labouring under the ca coethes scribendi.

Your obedient servant,

A. H. B.

Stoke Newington, July 13, 1846.

WESTERN CIRCUIT.

WINCHESTER, THURSDAY, JULY 16.

MR. HAWKEY'S TRIAL.—With reference to the point of law, whether a party inflicting a wound is answerable for any consequences which may ensue on the medical or surgical treatment of that wound—

Mr. Cockburn repeated the two objections which were made at the trial of Mr. Pym, and overruled by Mr. Justice Erle; first, that there was no evidence before the jury to make this a case of wilful murder There was no authority in the law of England for saying that, where a wound was inflicted by one party upon another, and in the course of the treatment of that wound an operation was performed of which the patient died, the party inflicting the original wound was guilty of wilful murder. In every one of the cases referred to by the text-writers (Russell on Crimes, vol. i., p. 505), the cause of death, though not immediately proceeding from the wound, was the result of natural consequences supervening thereupon, and the physical effects of that wound, such as fever or gangrene. But in this case the cause of death was a state of things supervening upon the treatment, not upon the wound. In the Scotch law, however, cases had occurred (Allinson's Principles of the Law of Scotland, vol. i., p. 145), which showed that that law recognised the distinction. The other objection was to the form of the indictment, which charged the prisoner with having fired a pistol loaded with ball, which inflicted a mortal wound, of which he died. He contended that the indictment was bad, for not truly stating the cause of death; it had held, on a case reserved, where a prisoner was charged with striking a man with a stick or stone, and thereby causing death, whereas it appeared in evidence that the prisoner struck the deceased with his fist, and knocked him against a brick or stone. The facts in this case were, that the prisoner discharged a pistol at the deceased, thereby inflicting a wound, which rendered medical treatment necessary, and that medical treatment caused another wound, of which other wound the party died. How then could the jury say that he died of a wound inflicted by a pistol ball?

Mr. Baron Platt overruled both objections, reserving the points. With reference to the first, the learned judge observed, if a man received a wound, certain consequences attended that wound, and if the party died of these consequences, his death was caused by the original wound. And so with respect to *bonâ fide* medical treatment. Suppose a man wounded by robbers, for which wound he received medical treatment and died from an operation; could it be said that the robbers were not guilty of murder? The last objection was met by the evidence of Dr. Stewart, who stated that the causes of death were two; the one primary, the pistol-ball; the other secondary, the medical treatment.

MIDLAND CIRCUIT.

NORTHAMPTON, WEDNESDAY, JULY 15.

CIVIL SIDE.

(Before Mr. Justice Coleridge and a Special Jury.)

Ashby and others, Executors *v.* Bates, Public Officer of the Argus Insurance Company.

This was an action by the executrix and executors of Richard Ashby, late farmer at Bugbrook, in this county, to recover from the Argus Insurance Company the sum of 500*l*, being the amount of a policy of insurance effected in that office in the month of April, 1844, upon the life of the said Richard Ashby, who died in the month of May, 1845.

Mr. Humfrey, Q.C., and Mr. Mellor conducted the case of the plaintiffs.

Mr. Whitehurst, Q.C., and Mr. Waddington, represented the office.

This cause was tried at the last assizes for Northampton, when a verdict was returned in favour of the office. A rule absolute for a new trial was afterwards obtained by Mr Humfrey in her Majesty's Court of Exchequer, on the ground of misdirection of the judge as to the mode in which the cause should be conducted, with reference particularly, due regard being had to the state of the record, to the right to begin and to reply. Our readers will remember that the Argus Insurance Company disputed the policy on the ground that the assurer, Ashby, had concealed a rupture with which he was affected, and of which he afterwards died. On the part of Ashby, it was alleged that the rupture had come on very recently, and only a few days before his death. A full report of the trial, with the medical evidence, may be found in No. 338 of the MEDICAL TIMES. The principal witness examined on the present occasion, in addition to those called on the former trial, was Mr. Partridge, whom the learned judge highly complimented on the manner in which he had given his evidence. He deposed, that taking all the circumstances and the appearances in combination—the smallness of the ring, the state of the omentum, the slightness of the adhesion, the healthy state of the intestine, the suddenness and violence of the attack on the day when the operation was performed, the largeness of the protrusion, the state of the patient in other respects, his paralysis, the emetic that he had taken, and all else that he had heard described, he was decidedly of opinion that the rupture was altogether recent. That was his conviction. The first surgeon, he said, had mistaken complex hydrocele for hernia. A truss was improper for irreducible hernia, unless when it was so made as to avoid pressure upon the part protruding. It would aggravate the evil. Had known many instances of persons, under favourable circumstances, themselves reducing old hernia supposed irreducible. If the first hernia had been down a long time, as from November to March, and been reduced and come down again, the appearances would have been different. Among other things the ring would have been larger. The concurrence of all things spoken to satisfied him that it was a case of recent hernia. Knew of no case, where the hernia had been down so long, and been pushed up and come down again with the appearances Mr. Nash had stated to have here existed.

Cross examined.—None of the symptoms of old hernia existed. The ring was small. The adhesion was slight. The omentum was healthy, except that the vessels were of course gorged. Hydrocele was sometimes mistaken for rupture. Thought that it might easily be so by an experienced man, where the hydrocele was going high up, or a thickening of the cord. Had himself kept a patient in the hospital for a day or so before he satisfied himself. That was a case of hydrocele with a thickening of the cord. Hydrocele and hernia might be mistaken, perhaps even when quite low down in the scrotum.

Cross examined by Mr. Humfrey.—In his opinion it was not possible that such a hernia as had been described could be reduced, leave no appearance, and come down again through the ring he had heard described. Thought it quite impossible that a hernia of such size as had been described, down on the 18th of November, the 9th of December, and in March, and pronounced irreducible on all three occasions by scientific medical men, and as being so bad that nothing could be done, could be placed back by the patient himself whilst in bed, who was almost all the while going about his usual business.

Mr. Justice COLERIDGE in summing up to the jury commenced by saying, that before he called their attention to the evidence, he must make one general observation. There was no ground whatever for treating this defence as an unfair or unjust resistance. If Ashby had mentioned, as he ought to have done and was bound to do, the fact of the swelled testicle to Dr. Robertson, all this expensive litigation would have been avoided. He then warned them to guard against prejudices. If their verdict should be against these poor people, it was the fault of the deceased man Ashby in making this unfortunate suppression. Who could wonder, after hearing the evidence, that the office should have thought it a matter that ought to be inquired into? He took first the issue of fraud in collusion with other persons, telling the jury that it was, of course, upon them who charged fraud to prove it. On the other hand, it was for the plaintiffs to prove to their satisfaction that Ashby, at the time of effecting the insurance, had not, and never had had, rupture; for that was one of the conditions upon which the policy had been granted. His Lordship proceeded through a laborious analysis of the evidence and dissection of the whole case, adverting to some of the most salient features, such as the first conviction of Dr. Kerr's mind, having once been strong it had perhaps become impossible to shake it by anything short of demonstration; the zealous leaning of the medical witnesses to the side which they had first taken up, their sitting by conferring with the counsel, instead of being away, as they ought to be, like the other witnesses, &c.; the great value of the testimony in such a cause of the operator himself, and of such unbiassed and skilful witnesses as Mr. Partridge, Mr. Coulson, and Mr. Calloway, all of whom he complimented most highly. The learned judge then proceeded over the whole evidence, with the aid of occasional observation and comment, placing the case in the most conspicuous and equable manner possible before the minds of the jury, to whose careful consideration he then committed it. The jury retired at verdict for plaintiff, thus reversing the former verdict.

MORTALITY TABLE,

For the Week ending July 18, 1846.

Causes of Death.	Total.	Average of 5 summers.	Average of 5 years.
ALL CAUSES	1053	898	968
SPECIFIED CAUSES	1050	892	961
Zymotic (or Epidemic, Endemic, and Contagious Diseases)	261	201	188
SPORADIC DISEASES—			
Dropsy, Cancer, and other Disease of uncertain or variable Seat	124	99	104
Diseases of the Brain, Spinal Marrow, Nerves and Senses	160	155	157
Diseases of the Lungs, and of the other Organs of Respiration	258	227	294
Diseases of the Heart and Blood-vessels	33	23	27
Diseases of the Stomach, Liver, and other Organs of Digestion	115	87	72
Diseases of the Kidneys, &c.	14	6	7
Childbirth, Diseases of the Uterus, &c.	11	9	10
Rheumatism, Diseases of the Bones, Joints, &c.	11	6	7

No. 357. SUMMARY. August 1.

PROGRESS OF MEDICAL SCIENCE,

INCLUDING CHEMISTRY AND PHARMACY.

France.

[From our own Correspondent.]

ACADEMY OF MEDICINE.

Meeting of July 21, 1846; M. ROCHE in the Chair.

THE PLAGUE.—In answer to the various orators who had successively attacked the *report* and its conclusions, M. Prus merely pointed out the contradictions existing in their statements, without bringing any new arguments forward in defence of his opinions.

HOTEL DIEU.

CLINICAL LECTURE BY PROFESSOR CHOMEL.

Intermittent Fever.

One of the most remarkable symptoms of intermittent fever, is undoubtedly the peculiar change of complexion observed in patients labouring under its effects. This change is a characteristic, earthy hue, quite distinct from the straw coloured shades of cancer, and accompanied by a sort of puffy state of the subcutaneous cellular tissue, which you will not meet with in carcinomatous subjects. When intermittent fever has prevailed for some time, the blood becomes impoverished, and souffle may be heard, as in anemia, at the first sound of the heart, and in the carotids, chiefly on the right side; you will also remark in most cases of chronic ague, a considerable enlargement of the spleen. A case was lately admitted into our wards, in which the organ descended two inches below the umbilicus and advanced so far below the false ribs, that it could be distinctly felt with the fingers, when the abdominal walls were placed in a state of relaxation. These points,—viz.: the alteration of the patient's complexion,—the abnormal sounds audible in the chief channels of circulation,—and the enlargement of the spleen taken into simultaneous consideration with the periodical attacks of fever, a description of which is needless in this place, are of the highest practical importance, not only for the diagnosis of the malady, but also for its effective treatment, a treatment which does not merely consist in arresting the progress of the fever with the sulphate of quinine, but also in the restoration to their functions, of the spleen and organs of circulation. It is almost always an easy thing to check the fever, but in a very great number of instances, the febrile attacks are only interrupted for a short time, and the organic lesion which originally gave rise to them still persisting,—their recurrency is inevitable.

We may add, that when enlargement of the spleen continues after the fever has ceased for some weeks, bark is of no further avail for the cure. In such cases, ferruginous preparations, when indicated by the anemic condition of the patient, have proved beneficial;—as to venesection and local depletion, they can only be injurious, although this method, combined with the exhibition of cinchona, has certainly been recommended as advantageous. We are of opinion that the cases benefited by this double method would have more rapidly and more safely been relieved by bark alone.

In most instances of intermittent fever, in which the paroxysms, but not the enlargement of the spleen, have yielded to the exhibition of quinine, the morbid hypertrophy of the viscus is extremely rebellious. Our predecessors were in the habit of recommending diaphoretics, laxatives, and vegetable diet; but the condition of success, the *sine quâ non*, is the removal of the patient from the noxious atmospheric influences which occasioned the disease.

In our opinion, the differences between the various forms of intermittent paroxysms of fever, have not hitherto been sufficiently taken into account. Many practitioners place a blind confidence in sulphate of quinine for the cure of all periodical fevers, and exhibit that remedy even in acknowledged cases of organic disease; it is far from unusual to meet with instances of consumption attended with evening feverishness, which the attendant physicians endeavour, need I say vainly, to subdue with quinine.

Essential intermittent fevers form a most remarkable order of diseases, inasmuch as they are perfectly distinct from all other maladies, and yet present in their symptomatic expression, points of contact with all other febrile conditions. They present a special type, are curable by a special method, and by their symptoms they may closely resemble almost all acute disorders. We also find that acute affections may under various circumstances assume an intermittent form. These observations shew, it is true in a feeble manner, the difficulties which may attend the diagnosis of ague, but at the same time point to the disease as a most interesting pathological manifestation. The existence of a specific cause to any disease necessarily points to a specific line of treatment: and this remark leads us to a point, which, at a future period, we will endeavour to develope before you, relative to epilepsy:—prizes and medals have been frequently proposed for the research and discovery of a cure for epilepsy. Now this appears to us an incomprehensible method of proceeding, because the causes of epilepsy are so very numerous, that it would be a sort of insanity to seek for a method of treatment applicable to all cases. It is not so, on the contrary, in diseases like rabies, and syphilis, which always acknowledge *one* cause, viz.: the introduction of a virus into the system. The specific of the latter, mercury, has long since been discovered, and analogy leads us to hope that for the treatment of the former, a specific drug may also be found.

HOPITAL DU MIDI.

CLINICAL LECTURE BY M. RICORD.

Gonorrhœa and Epididymitis.

With regard to the seat of gonorrhœa we may establish five degrees of the disease: in the first it occupies the balanic region; this is the most frequent. In the second, it invades also the spongy portion of the urethra up to the bulb; with the third, it extends to the membranous or muscular portion in the fourth the prostatic region is affected, and a fifth degree may be found in extension of the inflammation to the bladder itself.

In gonorrhœa of the balanic region, the glans is more tense,—the meatus injected, its lips puffed, and the urethra feels in the glans like a tightly drawn round cord. When the affection spreads to the spongy region, the discharge is less abundant than in the former variety; erections are attended with straining, but the organ is not bent, except when the cellular tissue surrounding the urethra, partaking of the inflammation, becomes deprived of its natural elasticity. When the membranous urethra is the seat of the disorder, it is in the perineum that pain is chiefly felt;—dysuria frequently complicates the malady, and a very troublesome sort of cramp, extending from the urethra to the scrotum. The inflammation accidentally spreads to a deeper region, the prostatic portion of the urethra, and the principal symptoms by which this occurrence is revealed, are vesical tenesmus, frequent, unsuccessful and imperious attempts to empty the bladder, and pains during defecation;—such are the special symptoms attendant upon each variety of acute gonorrhœa. Let us now examine its treatment.

In all cases in which the patient seeks advice during the first days of the existence of gonorrhœa, and previously to the establishment of well marked signs of acute inflammation, the surgeon should endeavour to check at once the progress of the disease; indeed we may lay down, as an invariable rule, that the abortive treatment should in every case be attempted, provided the structures surrounding the urethra be free from phlegmonous inflammation. The days are gone by when this treatment was supposed to be capable of producing strictures, which, it is now generally admitted, must be attributed entirely to the persistency of gonorrhœa and not to the methods of treatment successfully employed to arrest it.

The treatment I find most generally successful, is the exhibition of copaiba in capsules (6 to 12 daily), or cubebs, 1 to 2 ounces, together with one injection every day, containing from 10 to 15 grains of nitrate of silver to the ounce of distilled water. The injection should be as much as possible permitted to pass over the whole of the inflamed portions of the urethra, and therefore the patient should use no artificial means to guard against the imaginary evils attributed to the penetration of the injection into the bladder. If that penetration were possible, which the form and direction of the urethra permit us to doubt, the fluid would instantly be decomposed by its contact with the urine, and its passage over healthy portions of the mucous membrane, can do them no real injury. The combination of cubebs and copaiba in *one* preparation I reject, and prefer in all cases prescribing them separately, because if one fails in curing the gonorrhœa, the other remains as a precious therapeutical resource. If the abortive treatment prove unsuccessful, or if the acute symptoms of inflammation

have acquired a considerable degree of violence before the patient seeks advice, energetic antiphlogistic measures should be used before the exhibition of cubebs or injections. Baths, local depletion, and laxatives should then be employed, and when they have brought down the excitement in a great measure, the abortive treatment may be again resorted to.

Amongst the most troublesome complications of the first stage of gonorrhœa, we may mention dysuria; antiphlogistic treatment and local baths in luke-warm water, are usually sufficient to relieve it, but, occasionally, retention of urine is observed, and the surgeon is placed between the fear of injuring the urethra by the introduction of instruments, and the necessity of preventing over-distention of the bladder. In these embarrassing circumstances, we should first use every means to obtain evacuation of urine without recurring to the catheter,—such as leeches to the perineum,—cool lavements,—baths; but should the retention last more than 48 hours, a gum elastic catheter, of a middling size, and presenting a fixed curve, should be gently and cautiously passed in, and in most cases withdrawn after the operation.

Abscesses often form in the vicinity of the urethra; these should be opened at an extremely early period, in order to prevent the establishment of urinary fistula. We have also mentioned vesical tenesmus as a frequent complication, indeed, as a common sign of deep seated blenorrhagia; it is removed readily by a very simple method, consisting of the injection into the rectum of 4 ounces of cold water, with the addition of 15 or 20 drops of laudanum. When gonorrhœa is on its decline, great benefit may be derived from the following injection twice or three times a day:—R. aq. destill. rosar. ℥viij. Zinci sulphatis, plumbi s. acetat. aa. ℈j. m.

In chronic gleet it is of extreme importance to ascertain the cause to which the persistency of the discharge is due. The urethra should be carefully examined in order to discover any thickening or stricture of the canal; if none be found, astringent injections with wine, tannin, alum, iodide of iron (2 to 4 grains to ℥viii) will generally be found beneficial. In rebellious gleet, injections with copaiba or cubebs, have been recommended, but we cannot say we have ever found them useful.

Epididymitis.—It is exceedingly uncommon to meet with this complication before the third week of the existence of gonorrhœa; this remark acquires great importance, when it is coupled with the observation that few gonorrhœas resist the abortive treatment when properly applied: that treatment of the discharge becomes, therefore, the best prophylaxis of hernia humoralis. The left testis is frequently more frequently affected than the right, a circumstance which has been attributed to the passage of the sigmoid flexure of the colon over the spermatic veins; to the greater relaxation of the left side of the scrotum; and which appears to me to be promoted by the general habit of wearing the trousers on the right side of the scrotum. The custom of carrying a suspensory bandage is an excellent precaution which should by no means be neglected. In most cases the urethral inflammation is propagated along the vas deferens to the epididymis, and the swollen tube may be distinctly felt; in others, the inflammation seems to have been induced by sympathetic action, the vas deferens appearing to have no share whatever in its passage from the urethra to the testis. Orchitis is always in these cases preceded by epididymitis, and effusion of serum in the tunica vaginalis frequently accompanies the development of testicular inflammation. It is of great importance to distinguish epididymitis from true orchitis; their treatment, and particularly their prognosis being widely different. In the former the epididymis alone is hard, the testis preserving its natural elasticity; in the second, on the contrary, the issue of which is almost invariably fatal to the functions of the gland, the resiliency of the testis is exchanged for a dull hardness, as if it were *coagulated* by inflammation; the skin adheres to the swelling, is smooth, and deprived of the folds and wrinkles special to the region.

HOPITAL BEAUJON.

Case.—*Dislocation of the Astragalus.*

M. Robert.

F. B., Œtat. 22, fell on the 1st of July from a height of 20 feet, the ladder on the summit of which he was working, having given away under him. The patient's feet were engaged in the rounds of the ladder and the left was displaced, the sole being turned completely outwards. Reduction having been ineffectually attempted, the patient was sent to Paris, and admitted into hospital Beaujon on the 15th of July, 1846. On examination, the displacement presented the following appearances: the external edge of the foot was turned upwards, and the sole outwards; the external malleolus, concealed between the two articular surfaces of the os calcis, could not be felt; internally, in front of the internal malleolus, was a swelling, due to the presence of the astragalus, the head and inner edge of which were distinctly recognised. In the deep groove, by which are separated the two inferior articular surfaces of the astragalus, was engaged the process of the os calcis. Removal of the astragalus was determined upon, and accordingly the bone was laid bare by a crucial incision; great efforts of extraction were then employed, and only with partial success. The ligaments were, after the astragalus had been slightly moved, divided, and the bone was then extracted. But after the operation, the restoration of the foot to its proper position was not so easy as had been anticipated, the difficulty being due to the relative position of the external malleolus and os calcis. In order to liberate the malleolus, which had not been fractured, the foot was carried still more outwards, and replaced after having previously been pushed downwards. Continuous irrigations with cold water were prescribed on the joint, and three grains of extract of opium; on the second day the patient became slightly feverish, but the local condition of the foot has been daily improving. The cold applications have been continued to this day, July 25, and the patient is doing well.

Scotland.

Typhoid Fever.—A paper, read by Dr. Christison to the Edinburgh Medico-Chirurgical Society, on a typhoid fever, apparently originating in local miasma, is reported in the *Monthly Journal of Medical Science*. Dr. Christison admits the possibility that continued fever may originate simply in exposure to the effluvia of organic decay, and proceeds to draw deductions from this fact. One of the most obvious of these deductions is, that continued fever may show itself with the characters of an endemic or epidemic in localities extremely circumscribed. This has frequently occurred, and has, in some cases, given rise to suspicions of poisoning, from the exceeding virulence and circumscribed action of the local miasm; and experience shows, that events of this kind might frequently have been easily explained, had their observers been aware of the liability of fever to arise from the insidious emanations of concealed organic matter in a state of decay. Dr. Christison was led to make those remarks by a remarkable incident which lately excited a strong sensation in the neighbourhood where it occurred, and which went the round of the newspapers at the time, as a mysterious circumstance. In a thinly-peopled rural district of Peeblesshire, Mrs. W., the wife of an extensive farmer there, was attacked on the 22nd of January, with rigors, general prostration of strength, with great disinclination for food, to which vomiting was added five or six days afterwards. On the 30th of January she was visited by Dr. Macnab, who found her complaining of rigors, pains in the back and limbs, headache, slight intolerance of light, sore throat, and dryness of the mouth, a painful sense of palpitation along the course of the descending aorta, nausea, with occasional fits of vomiting, thirst, want of sleep, total loss of appetite, and great exhaustion. Her pulse was 92 and feeble, tongue covered with a very thick brownish yellow fur, the back of the throat red, the vomited matter partly mucus, partly bile, bowels constipated, evacuations dark and offensive, and the urine unusually yellow as if bilious. She had anxious expression of countenance, with suffused eyes; the temperature of the body was lower than natural, there was no pain in the epigastrium or either hypochondriac region. She gradually recovered under the use of laxatives, and diaphoretics. On the 9th of February, she was able to take food with relish, and had lost the tendency to vomit for some days, so that Dr. Macnab left her as convalescent. On the 13th, Dr. Macnab called to enquire for her, and to his surprise found her labouring under all her former symptoms in an aggravated form. The thirst was intense, nausea and vomiting very troublesome, pulse 100, intermitting, small, and very feeble; the tongue covered with a thick, dry, yellowish brown coating, the bowels very constipated, and the evacuations dark, bilious, and fœtid. The vessels of the conjunctiva much injected. There was no pain in the abdomen, and no appearance of petechiæ anywhere, nor any wandering of intellect. The remedies formerly of service produced no effect, and the symptoms went on speedily increasing in severity until the 19th, when, for the first time, she became incoherent, and on the same evening she died. No post mortem examination was permitted, but the body after death presented externally an emaciated appearance, and a peculiar yellowish colour. The patient was seventy years of age. On the 25th of January, Mr. W., a hale old man of seventy, the husband of the first patient, was attacked in a precisely similar manner. The disease took exactly the same course; the same relapse took place, and on the 18th of February he died. The body after death presented the same appearances, and speedily began to decay. The servant, Isabella M., also was attacked on the 26th of January, in precisely the same manner as in the previous cases. In her case, however, no abatement of the disease was produced by treatment; her strength was quickly exhausted, and she died on the afternoon of the 1st of February. Death was in this case preceded for twenty-four hours by delirium and stupor. The body presented the same external appearances. These were the only fatal cases; but in addition to them twelve other persons were more or less severely attacked with similar symptoms, and three or four others were more slightly affected. There were fifteen people either residing in the house, or much in it, during the day, and every one of these was so seriously affected as to be obliged to give up work, and to require medical assistance. Three or four others, who were only occasional visitors, were more slightly attacked, and two or three visitors who were in the house after Mr. W. was taken ill, all remarked that they were sick and uneasy in their stomachs. Of the fifteen frequenters of the house, who were attacked, all were seized within 14 days after the first case occurred. Two of these cases, those of Miss W. and Mr. J. W., were seen by Dr. Christison. That of Miss W. was remarkable from her having returned from the Isle of Skye (where she had resided at least three months) three days before the first case occurred. In nine days she was attacked with the same symptoms as the rest, and suffered severely. Dr. Christison was struck with the physiognomy of the diseases, as presenting something very different from that of ordinary infectious typhus of the same stage—the countenance being pale, the eye lively, the expression natural, and by no means oppressed; the mind clear and alert, and the strength, far from so prostrate as it was usually observed, in early convalescence from the late epidemic typhus. The disease attacked most severely all those, without exception, who resided night and day in the farm house. And the slightest forms of the disease occurred among the farm servants; who, though much in the farm house during the day, slept in their cottages, a few hundred yards off. No fewer than eighty-nine of the sick lay ill in cottages inhabited by other members of their families, without a single case of propagation of the disease having been observed in those localities. The farm house is situated near the confluence of the Line and Tarth, which both flow through rather open valleys, bounded by pastoral hills, rising about a thousand feet. There is but little wood within a mile of the house. The country is generally drained and dry, but to the westward, the fields on the north branch of the Tarth are irrigated with river water, the nearest point of these meadows being half a

mile from the house. The population of the district is purely rural, and very thinly scattered; and the only town within easy reach is that of Peebles, about seven miles distant. Suspicions of poison having occurred, Dr. Christison was consulted by the authorities. At first he suspected that the disease might have arisen from the use of diseased meat; but poisoning by diseased meat causes diarrhœa, and here constipation was present. Besides, no instance of natural death had occurred among the cattle of the farm for a very long period, and all the food consumed, was supplied by the farmer. Ordinary poisons were deemed out of the question—none had been seen about the farm for years; and several of the parties affected had never taken either food or drink on the premises, although in the house a considerable portion of the day. Besides, what poison produces such effects? A general endemic influence, or malaria, was inadmissible; neither the irrigated meadows, nor any other general cause could produce such a malaria as would fall with special virulence on the one house in question, and yet entirely spare all others in the valley. The want of resemblance to ordinary epidemic or infectious fever struck Dr. Christison's attention as something very remarkable, the disease was a typhoid fever, but yet not the typhus with which he was familiar. A local malaria was therefore the only conceivable cause left for consideration, no source of this, however, was known. Dr. Christison happening to be acquainted with the locality, recollected that the farmstead was situated on a rising slope behind the house; he therefore suggested that the drains might be defective, and that the soil around, and probably even under the house was bad, in consequence of becoming impregnated with decaying animal matter. Dr. Macnab made, accordingly, a searching investigation into the state of the drains and sewers at the farmhouse, and found them all closed up and obstructed with the accumulated filth proceeding from the privies and the farm yard. Dr. Macnab stated that the effluvia proceeding from these sources was very offensive, and was diffused through the atmosphere to a considerable distance around. Dr. Christison concludes, therefore, that the origin of this at first incomprehensible disease was at last explained, and recommends the circumstance to the attention of rural practitioners, as a probable explanation of the cases of fever frequently affecting numerous individuals in a circumscribed locality.

SUICIDE BY PRUSSIC ACID.—A case of suicide by Prussic Acid, read before the Medico-Chirurgical Society of Glasgow, is reported in the *Monthly Journal of Medical Science*. A gentleman, aged about forty-five, called at a tavern he was in the habit of frequenting, complained of being faint and asked to rest in another room, and to have a glass of water. He appeared agitated, and breathed somewhat laboriously. On being shown into a room he took his place, in a reclining position, on the end of a sofa, and a tumbler three parts full of water was placed on a table at his right side. He was not left alone for an hour after this, as there was a party drinking in the same room and the attendants entered it frequently. An hour afterwards all the glasses were removed with the exception of the tumbler of water which had been given to him, the door of the apartment was shut and he was left alone, occupying a similar position on the sofa to that already mentioned, breathing heavily, as if asleep. Three quarters of an hour elapsed before any one entered the room, when he was found in the same position, but sitting more erect, his head leaning forward, his arms lying easily by his sides and quite motionless. Dr. Fleming saw him in less than five minutes and found him quite dead, stretched on his back on the sofa. There was not the slightest action of the heart or lungs and from the coldness of the face, forehead, and hands, Dr. Fleming inferred that he had been dead half an hour. His features had a remarkably composed expression as if he had died easily, his lips had some colour, his jaws were closed, eyelids quite shut, the cornea prominent and glistening, and pupils half dilated; on opening a vein no blood flowed. Dr. Fleming found on examining his person, in the trousers pocket of the left side, a half ounce vial, *loosely corked*, labelled prussic acid, having a strong odour of that liquid, and wet as if recently emptied. The characteristic odour could not, however, be detected in the room, or at the mouth of the deceased. A small quantity of *water* had been spilled on the floor close to the sofa, and neither this nor the water in the tumbler had the slightest taste or smell of prussic acid, and the tumbler was said to be nearly as full as when given to him. On post mortem examination the odour of prussic acid was not detegible in the brain or blood flowing from it. The brain was much congested, and the ventricles contained serum. On opening the thorax and abdomen, the distinctive odour was strongly perceptible, even to the peculiar acrid sensation produced on the fauces. The pericardium contained six drachms of serum. The heart was of a natural size, but there was concentric hypertrophy of the left ventricle to a great extent; in other respects this organ was sound; all its cavities were perfectly empty and as clean and free from blood as if they had been washed. The aorta and larger arteries were also quite empty and flaccid. The veins were distended with blood, which was unusually dark coloured and perfectly fluid, the stomach presented no unusual appearances, and was preserved with its contents; the liver was enlarged, hard, and mottled, of a grey colour, and by no means loaded with blood; the spleen was large, soft, and engorged; the kidneys highly congested; the peritoneal covering of the intestines presented a reddish tint; the bladder contained above six ounces of urine; the contents of the stomach, when tested, showed the presence of prussic acid. It was ascertained that the deceased had procured half an ounce of prussic acid about a quarter an hour before calling at the tavern; the no odour of the acid perceptible in the or about his person within an hour after he had taken it, which would most likely have been the case had any of it been spilled, and the bottle was quite empty, therefore, Dr. Fleming concludes that the whole was taken. On analysis of some acid taken from the same bottle as that the deceased obtained the dose he took from, it was found to contain eight grains of pure acid in half an ounce. The scream was not heard in the present case, although several persons were in the adjoining room. There was found a considerable quantity of food, consisting of half digested animal food, bread, and apparently malt liquor (about eighteen ounces in all) in the stomach.

England.

The following are the only articles of interest to the profession in the last number of the *Lancet*.

JAUNDICE FROM AN ENCEPHALOID TUMOUR OBSTRUCTING THE HEPATIC DUCT.—Dr Ormerod relates the case of a female, aged 27, who was admitted into Bartholomew's hospital under the care of Dr. Burrows. When admitted her expression of countenance was dull and heavy; her conjunctivæ and skin generally of an intensely deep, jaundiced hue; pulse 96, full, and soft; tongue dry, and brown down the centre, pale at the edges; gums spongy, soft, and bleeding at the least touch. Bowels relaxed; the motions containing much blood. Abdomen full, soft, intolerant of severe pressure, which caused much pain in the right hypochondrium; urine abundant and high-coloured; had jaundice for three months, with drowsiness, weakness, and violent hæmorrhage from the mouth, nose, and alimentary canal. She was married and temperate; had always had delicate health, the catamenia having never been properly established. Three months before admission, she had a fall, which alarmed her a good deal and the next morning, the surface of the body had become jaundiced. Nine days ago, she had a rigor, followed by reaction; and from that time she had had oozing of blood from the gums, with epistaxis the day before admission, to a large amount. The alvine evacuations were at first clay-coloured, but had latterly been much darker. She had been treated by purgatives. On her admission into the hospital she was ordered five grains of calomel. During the night she was restless, constantly moaning. Bowels open several times, motions of pure blood; pulse 116, feeble; extremities cold; tongue dry, and brown. She was drowsy, but quite intelligent when roused. She gradually became comatose,—pulse 114, more and more feeble,—and died in the course of the afternoon, having passed a large quantity of blood in the bed just before death. The body was examined twenty hours after death: it was much loaded with fat; the limbs were rigid, the blood generally was fluid. Brain not examined. Lungs small, collapsed; tissues stained with bile. Heart small, and generally healthy: the right side of the pericardial surface of the right auricle crusted over with little dots of coagulable lymph, the remains of pericarditis. The stomach full of bloody mucus; mucous membrane generally *mamellonnée*, but in other respects healthy. Intestines, both small and large, full of dark fluid blood; their coats emphysematous in parts, and stained by the bloody fluid; in other parts, this discoloration was confined to the valvulæ conniventes, which, throughout the whole length of the canal, were much loaded with blood. In the duodenum was a soft, round mass, about the size of a walnut shell, white and pulpy, growing from, and apparently quite obliterating, the orifice of the common duct. The liver was large, reaching up to the third rib, of a dark, dirty-green colour; beyond this, the only thing to be remarked was the enormous size of the ductus cysticus and ductus communis choledochus, either of which readily admitted the little finger. The gall-bladder was healthy, being full of fluid bile; the pancreas and pancreatic duct presented nothing abnormal. The kidneys were natural in size, pale, yellow, beset with numerous small red ecchymoses; their structure was apparently healthy. The blood was fluid, while the rigor mortis was marked as usual.

ANEURISM OF THE ABDOMINAL AORTA.—Mr Cousins reports the case of a man, aged 66, admitted into the University College Hospital under the care of Dr Taylor; he was of short stature, lymphatic temperament, a smith by occupation; he had suffered occasionally from rheumatism, having on two occasions experienced severe attacks. Eighteen months before admission, he felt, shortly after dining, a severe pain at the crest of the right ilium, which in a few days became so severe, that he was unable to stoop or to dress or undress himself. This pain became of a constant gnawing character, and continued up to the time of his admission. It was much increased when he drew his breath. About five months ago, whilst employed on a large bar of iron, he threw back his head to see if the bar was straight, and he then felt a sharp pricking pain at the upper part of his abdomen, for a moment only. At bedtime he found in this position a rather hard spot, of the size of a dollar, which was not painful. He did not notice any pulsation for a month from this time, and it was then scarcely perceptible. The tumour increased with rapidity, and he lost strength; He had left his work nine weeks, and had been confined to his bed five weeks. For some time past he had been shivered in the evening; he was weak, and considerably emaciated, no anasarca. He could lie only on his back, with his knees drawn up; decubitus on either side gave increased pain in the back; countenance rather anxious; complexion sallow no lividity seen anywhere; tongue moist and furred in the centre; slight nausea after taking food; no tenderness at the epigastrium; the abdomen small and supple, and the walls thin. There was a globular tumour at the epigastrium, reaching nearly to the umbilicus, rising an inch and a half above the general level of the walls of the abdomen, at least four inches in diameter, and pulsating visi-

bly. There was not the least murmur in the tumour, nor in the course of the aorta, above or below it, and the tumour moved when he changed his position. Pressure over it, caused acute pain, felt about the right crista ilii, and a pricking pain in the tumour itself, which was otherwise free from pain. A continual aching pain, preventing him from sleeping, was complained of over the right half of the sacrum, and the adjacent part of the right ilium, not increased by pressure over those spots, but augmented by moving in bed. There was a slight pulsation on the left side of the spine in the lower part of the dorsal region, but no murmur. Pulse 66, moderately full, firm, and regular; of the heart's sounds, the first and the impulse scarcely perceptible, the second sound moderate; bowels costive, very irregular since he has been ill, sometimes not moved for a period of eight days. The patient, after nine days residence in the hospital, during which he continued in the same condition, died suddenly in the morning. On examination after death, the tumour in the epigastrium was found to have quite subsided. The face and lips were quite blanched. In the cavity of the abdomen there were twenty-one ounces of coagulum and forty-one ounces of serum of blood. The aneurism was of the size of the coagulum and bounded behind by the vertebral column; the bodies of the first and second lumbar vertebræ were much diseased on their left side; the duodenum was strongly adherent to the sac. The opening of the aorta into the upper part of the aneurism admitted the points of two fingers, and the artery was larger a little above this; the opening from the aneurism below, and the artery itself, were much narrowed; this opening was situated about two inches above the bifurcation of the aorta, the dilatation beginning immediately below the renal arteries. The coats of the vessel which composed the sac were not much thickened; there was a coloured fibrinous deposit on the internal surface in front, towards the left part; near the inferior part was an opening into the sac of nearly the size of a halfpenny; the edges had a lacerated appearance, and the walls were thinned at this part. Under the lining membrane of the aorta was a deposit of calcareous and atheromatous matter. The arteries at the base of the brain were all more or less diseased, especially the basilar artery; the surface of the kidneys rough texture rather dense and mottled; cortical part not atrophied; the spleen very soft. Intestines throughout very pale. Heart: weight, twelve ounces; pulmonary valves allowed a little regurgitation; the aorta admitted the points of three fingers, and was larger than the pulmonary artery; the right ventricle and auricle empty, ventricle rather small, but otherwise healthy; the left ventricle contracted; the walls thicker than usual; substance pale; some spots on mitral valve; orifice of natural size; valves slightly thickened: left auricle quite natural. The lungs contained scarcely any serum or blood. The other organs presented no appearances worthy of note.

Aneurism of the Femoral and Popliteal Arteries.—Mr Hawkins reports the case of a man, aged 30, of thin, sallow, unhealthy appearance, who became a patient in the Cheltenham Hospital, in consequence of Aneurism. About three years before seeking advice, this patient noticed a swelling, the size of a bantam's egg, in the ham, to which his attention was attracted by a sharp pain. After three years (in July 1839) he sought advice, when there were discovered two pulsating tumours in the left lower extremity, one of the size of a duck's-egg, about five inches below Poupart's ligament, the other, the size of a lemon situated in the ham. On several occasions he had had hæmoptysis, but, according to his own statement, not to an alarming extent. The sounds of the heart, heard all over the chest, considerably obscured the respiratory murmur; the breathing was hurried, and he had slight cough; pulse full and bounding, always above 100. Under these circumstances, an operation was considered inadvisable. On the 31st. of August, he was again seen. The tumour in the thigh had remained stationary. The swelling in the ham had increased considerably; the pulsations had ceased, and the integuments covering it were of livid colour; the pain in the limb was so great as to deprive him of rest. Pulse 120. He was immediately admitted into the hospital, kept in bed, and, from fear of hæmorrhage, a tourniquet was placed over the femoral artery, just below the upper swelling. The next day the dark livid discoloration of the integuments was more extensive; there was obvious danger of immediate hæmorrhage, and on the following day (September 2nd) the external iliac artery was tied in the usual manner. The moment the ligature was tightened, all pulsation ceased, and the patient complained of pain in the limb. The edges of the wound were brought together by sutures; a light compress and bandage were applied, and flannel was rolled round the limb. About three ounces of blood were lost during the operation. Towards evening he complained of pain and numbness in the limb; the temperature, however, was natural pulse; 120. On the sixth day after the operation, both the femoral and the popliteal tumours had much diminished in size; the limb was cold; the foot livid. The wound made at the operation had in great part united. On the eighth day, the tongue was brown and dry; respiration hurried; eyes glassy, and the look vacant; pulse 120. A slough had formed upon the buttock. The day after the foot had mortified, and a large slough had formed in the popliteal space The discharge from the limb became extremely fœtid and on the 29th day after the operation the patient died On *post mortem* examination the pleuræ were found firmly adherent on the right side. The left ventricle of the heart was dilated as far as the commencement of the aorta. Abdominal viscera healthy. The ligature had been applied an inch from the origin of the epigastric artery. A firm plug was formed within the external iliac artery, both above and below the ligature. The femoral aneurism was carefully dissected out. At the lower part of the sac, the femoral artery divided into two branches of equal size; one communicated with the sac of the femoral aneurism, the other ran over the sac, and communicated with the popliteal aneurism, which had been destroyed by sloughing.

Epilepsy.—Mr Charles Gibb, house-pupil to the Newcastle Infirmary, reports the case of a sailor, aged 36, who was first attacked by epilepsy 18 months before, without apparent cause; he had considerable vertigo, but no pain; dim, wavering eye-sight, with slightly contracted but sensitive pupils; tinnitus aurium; a compressible slow pulse, and regular bowels. After the first fit he had a little vertigo, and was bled, but continued pretty well for six months. She... without cause, the fits returned with scarcely any intermission, for nine days. During this period he was often bled, and he remained unwell afterwards for six months; was again attacked two days before admission into the infirmary; had three severe fits; had been bled and purged. He was cupped and purged, and mercury was administered so as to affect his gums slightly; leeches were also applied to the septum nasi twice a week. This treatment was continued during a month without benefit. The patient was then ordered half a grain of nitrate of silver thrice a day with purgatives. Some little benefit arose from this change; as the fits returned however, and the patient complained of weakness, he was ordered "*to omit medicines and have nourishing diet, with* ONE OF THE HAGUE POWDERS FOR EPILEPSY *twice a day, and an aperient injection occasionally.*" This treatment was continued for a fortnight, leeches being once during that time applied round the anus. At the end of this time a syphilitic taint was suspected in consequence of pains in the shin bones. Blue pill, iodide of potassium and sarsaparilla were therefore resorted to. Under this treatment he improved and was dismissed.

*** We cannot too strongly reprobate the countenance given to quackery, by the mention, without strong protest, in a medical journal, of the above named notorious nostrum, as having been prescribed at a large infirmary and by a medical practitioner of some standing.

Land Scurvy.—Dr. M'Cormack relates a case, which he considers to be Land Scurvy, produced by eating diseased potatoes, and which Dr. M'Cormack states, he has every reason to believe is very prevalent. The patient was a girl, aged 16, who was said by her mother to have taken "the complaint that was going through the country." The father described the disease also as having commenced with a pain in two of her front teeth, producing great swelling of the gums, and afterwards enormous swelling of the head. The patient was a factory-girl in a flax-mill, where she was exposed to great and sudden changes of temperature, also to great fatigue; the heat of the mill was so intense that her clothes were always saturated with perspiration. Her hours of work were from half-past five in the morning till past seven in the evening. From the extreme wretchedness of the family, her food had been of the most scanty and unwholesome nature, the potatoes they used being all more or less diseased, and milk being an article of diet they had not been able to indulge in for months. She had complained, for about fourteen days, of a pain in two of her front teeth, which was of so acute a character as to preclude sleep at night, and which caused equally intense suffering during the day; also of chilliness, and disinclination to move or exert herself; but still she struggled against the disease, as both herself and her family were dependent for livelihood on her earnings; and she continued going to the factory until eight days before Dr. M'Cormack saw her, when she was unable to quit her bed from excruciating pain in all her joints, and in the small of her back, and burning heat of skin. She had not slept for several nights, during which, her mother said, she raved incessantly; had not been able to eat any food for four days, from the soreness of her gums, mouth, and throat; had felt a sense of weight, accompanied with pain, in the region of the heart; palpitation was excited by the slightest movement, and there was a general muscular soreness over the whole body. The pain in her teeth was excessive, there was no appearance of caries in any; the gums, especially of the lower jaw, were swollen, painful, spongy, and bled on the slightest touch; even the attempt to swallow caused an oozing of blood. On examination, the teeth were found to be loose, and extremely painful; fauces and mouth inflamed, and ulcerated in patches; tongue flabby, and thickly loaded with white fur; breath horribly fœtid; great difficulty in swallowing; pulse 130, small and feeble; muscular pains excruciating; joints swollen and very painful; skin over the whole body tense, tumefied and of a preternaturally dark colour; vibices scattered over the limbs: great prostration and despondency; constant involuntary sighing; face and head enormously swollen; countenance pallid, unmeaning, and indicating indifference of her fate; no sleep, from the pains of the joints. The bowels had been obstinately constipated for several days, and her mother had given her a dose of senna and salts the evacuations caused by which brought on such extreme exhaustion, that she had several fainting fits in rapid succession. Urine scanty and high-coloured; the belly hard and dropsical; heat of skin intense; the two teeth in which the pain commenced had split in two perpendicularly. Dr. M'Cormack states, that as the poverty of the girl's parents prevented her obtaining the only remedies from which she could derive benefit,—an improved diet and regimen, she continued to get gradually worse. Dr. M'Cormack has also since met with a similar case, in a milder form, occurring in a very delicate female, aged 19, exposed to cold, hardship, great fatigue, and want of proper nourishment. This patient was attacked with sudden prostration of strength, fainting, acute pain in the abdomen, excruciating muscular and articular pains, especially attacking the neck, shoulders, and back; the skin so sore that the slightest touch caused her to cry out. She was unable even to turn in the bed; bowels confined, urine scanty and high-coloured; pulse 130, small and feeble; great heat of skin; tongue loaded; breath fœtid; face and head enormously swollen; became flushed several times in the day, and pallid afterwards; great despondency, and headache. She continued in this state for five days, when she complained of her teeth being so loose that she could not eat; the mouth was sore; gums spongy; and bleeding on the slightest touch. She was improving gradually under a generous diet, with bitters, such as quinine, compound decoction of gentian, &c.

Asphyxia Idiopathica.—Mr. Robins relates the case of a young woman, aged 19, who had been married only a few weeks, to whom he was called about half-past five in the morning of the 30th of December, 1845. He found her in her night-dress, in bed, lying on her back, with the arms extended on either side, her head being supported by her mother-in-law. The skin was still warm, and rather moist; the eyelids were partially closed, and the pupils dilated; the lips were nearly in apposition, appeared rather swollen, and bluish, and there was a little white froth between them. The legs were nearly in contact, and lying straight down the bed. The external appearance of the body was pale, and there was no mark of violence on any part of it. The bedclothes were not in confusion, and there were no stains on the pillows. On looking about the room, nothing of a poisonous nature was discoverable. As far as Mr. Robins could learn from her friends, the patient had always been in good health, though occasionally subject to fainting fits, and a feeling of flatulency. She had been in service nearly up to the time of her marriage, and a surgeon with whom she had recently lived nearly twelve months, stated, that during that time she had never complained of bodily illness. Mr. Robins had seen her for the first time, three weeks after her marriage, in conse-

quence of slight sickness, headache, and pain in the loins; she had passed one of her usual periods of menstruation without having seen anything. An inquest was held on the body, and a post-mortem examination made 33 hours after death. The skin of the anterior parts of the body was very pale, that of the posterior dark-coloured. The body generally was plump and well formed. There was no appearance of bruise or other external injury. A slight white froth still existed between the lips. On cutting through the skin, there was a considerable layer of fat, and the muscles were red and well developed. On opening the cavity of the abdomen, the external appearance of the organs was that of perfect health. There was nearly a pint of serous fluid in this cavity. On removing the sternum and ribs, the contents of the chest presented the same healthy appearance as the abdominal organs. There were about three ounces of fluid in the right pleura, and about half that quantity in the left. On opening the pericardium, nearly two ounces of fluid were found in it. The heart itself presented a very healthy appearance, but it was very soft, and of small size. On cutting into its right half, both the ventricle and the auricle were found exceedingly thin, and Mr. Robins considered the ventricle dilated; only a small quantity of blood escaped from either cavity. The left side was quite empty, as was the aorta for some distance, but both ventricle and auricle were perfectly healthy; so were the valves on both sides of the heart, as well as the large vessels. On examining the lungs, they were found considerably engorged with black blood, but there was no other appearance of disease in their structure. Mr. Robins ligatured the two extremities of the stomach, and removed it from the body for further examination. It contained less than two ounces of rather thick fluid, of a reddish colour, which was preserved. On laying open this organ, he found the mucous membrane of a large portion of the smaller curvature, as well anteriorly as posteriorly, of a deep-red or purple colour, which did not terminate abruptly; but the other parts were nearly natural in appearance, and both the cardiac and pyloric openings were quite healthy. The duodenum and first portion of the small intestine appeared congested, but the bowels generally were free from any morbid appearance, and were nearly empty. The spleen was very much engorged; the liver, also, much beyond its usual size, but its structure seemed healthy, and the gall-bladder was half filled with healthy bile. The kidneys, especially the right, were large from congestion, but they were healthy in structure, and so was the bladder, which was empty. The uterus was enlarged from pregnancy, which, in the opinions of Mr. Newport and Mr. Girdwood, had advanced to the ninth week. There was a sore on the right labium, nearly as large as a sixpence. On removing the skull-cap, about two ounces of fluid black blood escaped, most probably from a rupture of the sinuses, for these were afterwards found empty. The veins of the dura mater were congested, so also were those of the brain itself; for, in cutting across its substance, a great many dark spots were seen; but after carefully examining every portion, no other unnatural appearance was found. The stomach and its contents were taken away for further examination. No improper substance was found, however, on analysis. At the inquest, the following facts appeared in evidence:—That she had been married only ten weeks. That she appeared in her usual good health, with the exception of occasional morning sickness, up to the evening preceding her death, when she felt a little faint, and complained of a swelling of the right leg below the knee. She, however, ate heartily at tea-time, and had some brandy in her tea, to relieve the faintness. She had the leg rubbed with hartshorn oil: she also took two common aperient pills between nine and ten o'clock, and went to bed with her husband in good spirits. The brothers slept in a room adjoining, and one of them, who did not get home till twelve o'clock, had occasion to speak, on his return, to the husband of deceased, and as he could not awake him, the deceased said, laughingly, "Tickle him up." She then appeared quite well. She had frequent occasion to get out of bed, from the action of the pills; and soon after five o'clock her husband said he was awoke by a noise, which he found to arise from her having fallen down by the side of the bed. He lifted her in, and called his brothers; she told one of them to go for his mother, as she was very ill. He said she looked very pale, and asked for a glass of water, but when it was offered to her she did not take it. Almost directly after this, her husband said, she gave three loud screams, and after that never spoke. The distance to the mother's was but short, but before her arrival she was dead. The inquest was adjourned, and a re-examination of the body instituted, the appearances of the pharynx and œsophagus being particularly noticed. No trace of disease appeared in the trachea, and the bronchial tubes contained a little frothy mucus only, which was not bloody; the whole of the blood in the body was black and fluid. Mr. Robins therefore concluded that idiopathic asphyxia was the cause of death, and a verdict of death from natural causes was returned.

ORIGINAL LECTURES.

A COURSE OF LECTURES ON PRACTICAL MIDWIFERY.

By EDWARD RIGBY, M.D.

Fellow of the Royal College of Physicians, Senior Physician to the General Lying-in Hospital, Lecturer on Midwifery at St. Bartholomew's Hospital, Examiner on Midwifery to the University of London, &c.

Delivered last session at Bartholomew's Hospital, and revised by the Professor for the "Medical Times."

SPURIOUS PAINS AND TREATMENT OF LABOUR.

At our last meeting, gentlemen, I described to you the process of natural labour; it now remains for me to say a few words on the spurious pains to which, at the commencement of labour, many women are subject. The procursory pains of labour are liable to be perverted by many circumstances, and their diagnosis from the true uterine contractions of early labour is a matter oftentimes sufficiently puzzling to the young practitioner. Costiveness is one of the most frequent causes which give rise to the *dolores spurii* as they are called; in fact any irritation in the primæ viæ soon communicates itself to the uterus, and deranges its action. Plethora is also a cause, for the uterus is so much engorged that its action is impeded, and in some cases a state bordering on inflammation is induced. Spurious labour pains are not unfrequently of a rheumatic character, and when this is the case they are productive of much suffering to the patient, although the uterine contraction may be so trifling as not to produce any perceptible effect on the os. Rheumatic pains of this nature are commonly produced by exposure to damp and cold, in common with the other forms of rheumatism, and are generally connected more or less with bilious and gastric derangement. As I before said, these pains are not always easy of diagnosis, but it is of considerable importance to ascertain certainly their presence. You will recollect I told you that genuine labour pains come on at regular intervals, and rise by degrees to a certain degree of intensity and then gradually subside; the earlier pains are situated in the back and loins, and are of a dull aching character; the fundus, and os uteri are perceptibly affected by them, the fundus becoming hard and firm, and the os tense; the spurious pains on the contrary come on suddenly and at irregular intervals; they are of a sharp twinging character; are felt in the abdomen, and produce little or no effect on the os and fundus of the uterus. By stethoscopic examination you have safe means of diagnosis. On this subject Dr. Hohl says, "If we direct our attention to the changes of tone which the uterine pulsations present during auscultation, we shall find them generally stronger, more distinct and varied in tone during labour: and this is especially the case just before a pain comes on; even if the patient wish to conceal her pains, this phenomenon, and more especially the rapidity of the beats, would enable us to ascertain the truth. The moment a pain begins, and even before the patient herself is aware of it, we hear a sudden short rushing sound which appears to proceed from the liquor amni, and to be partly produced by the movement of the child, which seems to anticipate the coming on of the contraction; nearly at the same moment all the tones of the uterine pulsations become stronger; other tones which have not been heard before, and which are of a piping resonant character, now become audible and seem to vibrate through the stethoscope like the sound of a string which has been struck and drawn tighter while in the act of vibrating. The whole tone of the uterine circulation rises in point of pitch. Shortly after this, viz:—as the pain becomes stronger and more general, the uterine sound seems as if it were to become more and more distant, till at length it becomes very dull and altogether inaudible. But as soon as the pain has reached its height and gradually declines, the sound is again heard, as full as at the beginning of the pain, and resumes its former tone, which in the intervals between the pains, is as it was during pregnancy, except being somewhat louder. This is the course of things if the pain be a true one, and attain its full intensity; when the pains are false or irregular, it is very different; the uterine sound either remains unaltered or increases only for an instant, or its seeming increase of distance as above mentioned, is not observed." I have been in the habit of comparing the sound of the uterine circulation, to that produced by a stone thrown obliquely over a smooth piece of ice, which flying along in a succession of bounds, produces a sharp twanging sound each time that it strikes the ice. The treatment of spurious pains will depend in a great measure on their cause. When constipation is present, castor oil is the medicine which is most frequently given from the mildness and speed of its action; afterwards if there be symptoms of irritation from flatulence, a carminative mixture may be ordered where there is time for its action. I know nothing better than a blue pill over night and a dose of rhubarb and magnesia the next morning. If after free evacuation of the bowels these pains still continue, an opiate will be useful. When called to the case, too late to give a purgative, a large enema of chamomile tea, as is almost always done abroad, should be given. When excessive plethora is the cause, and the patient is young and sanguineous, a small bleeding will remove this state, and a dose of opium should be afterwards given. It is of much consequence to check these spurious pains, as the uterus does not act properly as long as they are present. Should you be satisfied that the patient is of a rheumatic diathesis, after a purgative give Dover's powder and diaphoretics. Attention to the state of the bowels towards the close of pregnancy, will often effectually prevent the inconvenience of spurious pains; indeed, I cannot, gentlemen, too deeply impress the necessity of this care on your minds.

I now come to speak to you of the *treatment of labour*. Usually speaking the glance of an experienced eye can tell pretty nearly whether a labour is likely to be a favourable one or otherwise, and this information is obtained from the general appearance of the patient. You will bear in mind that the more active and the more symmetrically formed she is; the more equally distended her abdomen; and the more exercise she has been able to take, even up to the time of her labour, the better you may expect her to pass through this process. I have before mentioned to you the necessity of emptying the rectum by injection; I must again allude to it here because it belongs to the treatment of labour, and because I cannot too strongly impress it on your minds. The labour is rendered more cleanly by it; and its duration is certainly shortened in many cases, as sometimes a mass of hard scybala is brought away from the rectum, which had it been allowed to remain would have proved a source of serious obstruction, and have tended considerably to retard the labour, as well as to obstruct the return of blood from the pelvic viscera, thus increasing the risk of hemorrhage. Merely for the sake of cleanliness, you should direct an enema to be administered. In this respect the continental accoucheurs are in advance of our own practitioners; for in Germany they almost always administer a large enema at the commencement of labour. I have before told you that this too will prevent the occurrence of spurious pains arising from constipation.

The uterus alters its shape very considerably during labour; as the process advances and the liquor amni drains off, the uterus becomes pyriform, its fundus more or less flattened, and the earlier this state occurs, the more effectual are the pains; where on the other hand the abdomen is very large, and the uterus much dis

tended, either by a large quantity of liquor amni, twins, a very large child, or any other cause, the pains are slower and less powerful. If however the over distention arise from excessive quantity of liquor amni, when some of this has drained away, the pains become more active.

The position of your patient during labour is important during the first stage, especially in primiparæ, in whom this stage is usually tedious it is not necessary that the patient should take to her bed; on the contrary you should endeavour to make her believe that labour can hardly be considered to have commenced, and you should encourage her to move about, or sit up as she may feel inclined. Till nearly the end of the first stage let her walk about or stand or sit, or, if she likes, go about her usual occupations. At the same time you will be careful to have every thing in readiness for her, in case the labour should progress rapidly.

The best position for the patient to take during labour, is a subject which has been much discussed; even at present it varies much in different countries. The earliest position of which we have any record, appears to have been a half sitting, half reclining posture, and is described in the first chapter of Exodus. This posture was revived in comparatively recent times by Ambrose Paré, who in 1570 invented a labour chair, which he used in preference to bed. This chair consisted of a reclining back, a seat with a hole in it, a board to press the feet against, cushions, and arms or straps to hold by in order to fix the trunk and upper extremities. You see, therefore, gentlemen, that the whole principle of these chairs is bad; we do not want rapid and violent labours, but safe ones. These chairs are accordingly much less used than they were formerly, in fact they may now be considered as entirely exploded. Although even now I believe they are used a little in some remote parts of Germany

In France women are delivered on their backs, lying on a low bed placed on the floor, which has been not inaptly termed *lit de misère*. In England we place the patient on her left side a position which has many advantages; the patient is more comfortable, and is not annoyed by seeing the proceedings of the practitioner who sits behind her; she is unable to exert an undue degree of force when the presenting part is passing the os externum, and thus laceration of the perineum is less likely to happen, as time is given for the parts to dilate; and from her knees being kept together, the chance of perineal laceration is rendered much less probable. The side position seems also to be the most natural one. An experiment was tried many years ago, at Heidelberg, to see what position the patient would naturally take. A young girl completely ignorant of what was expected of her was left entirely alone, and towards the close of her labour, when the last expulsive pains were about to occur, she naturally assumed this posture on her left side. At Berlin they use the labour-cushion, which seems to be a modification of the labour-chair. It was first proposed by Unger, and afterwards employed by the late professor Von Siebold of Berlin. It consists of a thick half mattress with a depression beneath the nates. This is all very well, but I must say I see no particular advantage possessed by it over the ordinary position, which is adopted in this country. The pains of the first stage of labour, are rendered much easier by frequent change of position, you will therefore so far encourage your patient to move about; but when the pains become more severe, and of longer duration, you will direct her to lie down, and you will take advantage of this opportunity of making a vaginal examination; indeed as soon as the os uteri has become somewhat dilated, this examination has become necessary. In popular language the act of examining is called bring a pain; but you will by no means take a pain, gentlemen, on the contrary, you will rather examine between the pains. You can gain no information during a pain, except with regard to the degree of dilatation of the os uteri, and you will always find this tight enough during a pain. In the interval between the pains, on the contrary, the os is relaxed and admits the finger more readily; the bag of membranes is not distended, and is therefore not liable to be ruptured during the examination; and you are able to feel the part presenting more easily through the loose membranes. When the os uteri is almost fully dilated, the patient should by all means go to bed, as the membranes may rupture, especially in primiparæ. If you have not already made an examination, it is absolutely necessary that you should do so now, both to ascertain the presentation, and to inform the patient of the progress of her labour. All aids to the patient in the shape of towels to hold by, or foot-boards to press against, during this stage of labour, are worse than useless, they are injurious; straining cannot hasten the progress of the labour, and it may be a serious injury by prematurely rupturing the membranes. As soon as the membranes are ruptured, you should repeat your examination; it may be that you have not quite made out the presentation, and now you can decide on it; or the cord may present; in which case it comes down into the vagina and cannot escape notice; in women who have had many children also, the head often remains very high in the pelvis until this time, so high that it can with great difficulty be reached by the examining finger, and in these cases you are obliged to wait for rupture of the membranes before you can ascertain the presentation with anything like certainty.

All attempts at artificial dilatation, I need not tell you are most improper, and all oily or unctuous applications to assist dilatation only prolong labour by irritating, and inflaming the os. Much has been written on this subject, and among others Stein has written a treatise "De Nova Enchyrasi ad partum accelerandum." As I have before told you however, in primiparæ, who are flushed and with a hot and dry vagina, a small bleeding will, when the pains are irregular, produce wonderful effects; the pains become regular, and act more powerfully, and the os uteri swells, and dilates rapidly. If the os uteri be dilated and the membranes ruptured, but the head not coming down rapidly, you need not keep the patient in bed. You may allow her to move about if she desire it, indeed in the Baltic provinces of Russia, labour is constantly conducted in the standing or rather walking position, but this position is injurious if too long continued; in most primiparæ, however, a change of position affords much relief. I must again caution you not to allow your patient to strain at this stage of labour, and I insist on this because, nurses and injudicious friends often advise the patient to do so. An old friend of mine, advised me when a student, never to allow any patient to strain until she could not help it. Very good advice, gentlemen, which I have never forgotten. Madame La Chappelle, supposes that may increase the activity of the pains by pressure on the perinœum. Although I can hardly agree to this, yet I am quite certain we may greatly assist the expulsion of the head by pressing it forward with the hand on the perinœum.

On no subject, is the accoucheur more tormented than as to the probable duration of labour; the patient is naturally anxious, and expects after your examination that you will be able to give her an idea, when her sufferings are likely to terminate. Nothing, gentlemen, is more uncertain; in fact, the only criterion I know of, is that mentioned by Wigand, who says that "the vagina be cool and moist and fully dilated throughout, the labour will be speedy; if however, the canal be dilated at its upper part, and contracted near its orifice, the first part of the labour will be speedy, and the latter part tedious; and if the canal be contracted at its upper portion, and dilated at its lower, the commencement of the labour will be tedious, and the latter part rapid. When you are teased by your patient, gentlemen, you must not express your opinion as to the time when the labour will be over; you must turn the matter off in the best way you are able; recollect that one unguarded assertion unrealised, loses for you, your patient's confidence.

The character of labours is often hereditary: a patient will tell you that her mother had tedious and protracted labours, and often you find two or three sisters of the same family, remarkable for the same peculiarity. As a rule I have observed, that if a woman have very easy catamenial periods, she will have very lingering labours, and vice versa.

Injury of the perinœum has been noticed from the earliest period, of which we have any records, and is mentioned in the book of Genesis, as having occurred at a birth of twins; among the vulgar the perineum has been considered a useless appendage hindering labour. A curious case occurred at Maunheim, some years since, illustrative of this idea, a midwife was sent to the House of Correction for slitting up the perinœum during labour. At our next meeting, gentlemen, I shall resume the subject of the treatment of labour with the management of the perinœum.

A COURSE OF LECTURES ON DISEASES OF THE SKIN.

By JAMES STARTIN, Esq., Surgeon to the London Cutaneous Institution.

LECTURE XVII.

ACNE (*continued.*)

THE TREATMENT OF ACNE.

According to Willan and others.

GENUS.	SPECIES.
Acne	Simplex Punctata Indurata Rosacea

As proposed by Startin.

GENERA AND SPECIES.

ACNE

Simplex	Localis	Disseminata
Pustulosa		Confluenta
Rosacea vel	Generalis	
Erythematosa		Inveterata

Gentlemen,—Medical writers of all grades, and from the earliest times, have held the successful treatment of *Acne*, particularly of the species termed *Rosacea*, to be not the least difficulty which attends the art of healing; but yet, in justice to myself I must observe that in carrying out fully, the views detailed, when speaking of other cutaneous diseases, I have certainly been very commonly rewarded by a successful result. As usual the causes must be diligently sought for, and removed by appropriate remedies, measures, or restrictions. Local and general means for increasing the cutaneous circulation and determining the blood to the surface, will generally produce a favourable change in the malady, and I have found the hot air bath, with, or without, sulphur fumigations, of great service, whilst chalybeates, combined with the mineral acids, with the vegetable bitters and with iodine, have furnished my most useful internal agents; arsenical preparations, and mercurials, unless the latter should be indicated by hepatic or visceral disease, *are not indicated or required* in these cases, nor when used, have they appeared to me to be attended with benefit. The diet of patients afflicted with acne requires to be mildly nutritive, nor must a proper proportion of alcoholic stimulus be discarded, otherwise the digestive organs, which are seldom in a healthy condition, are apt to neglect their office. Vegetable acids, and antiscorbutics as they are called, and vegetable diet drinks, are in my experience worse than useless, I do not know whether I dare include sarsaparilla in this condemnation, though I feel inclined to do so, as I am aware that it is the strong hold of many of my medical brethren, whose experience must differ from mine, if sarsaparilla has proved of greater utility in these diseases, than the same quantity of mildly nutritive fluid. The external local treatment of acne is not the least important and must be regulated entirely by the stage and condition of the disease. In its commencement when a loaded state of the sebaceous

follicles is the most prominent symptom, moderate frictions with the flesh brush so as to open the pores and the extraction by pressure, of the larger collections of sebaceous matter, (the outlet of the follicle being dilated with some pointed but not too sharp instrument,) will be required; whilst a weak spirit lotion and the use of oatmeal, instead of soap may be enjoined. As the disease advances, and the suppurating points are numerous, large and painful, the vapour douche on the face, mercurial ointment with camphor, white precipitate with camphor, or the *Topique contre acne* of the Hopital St. Louis may be recommended: the latter is composed of slaked lime ʒ i. zinc ointment ℥i. and camphor ℈i. From fifteen to thirty grains of the ioduret of sulphur to an ounce of lard is also a useful application, as is a weak solution of bichloride of mercury in milk of bitter almonds, or thin quince seed mucilage. The following lotion, not to be found in books, you will find occasionally very efficient, hyposulphite of soda, ʒj. to ʒij. sulphate of alumina, ʒj. to ʒij rose water ℥viiss. cologne water ℥ss. for a lotion to be used by washing the part with a linen rag twice or thrice daily. Of course these proportions are not applicable in every case, but the composition is very useful in removing the unpleasant yellow stains of the cuticle as the acne declines, and it is perhaps more applicable to acne rosacea and pustulosa, than to the other varieties of the disease, as it always relieves the attendant itching. There are, perchance, few complaints which have at one time or other, produced so many nostrums as those under our consideration, and therefore I must refer the curious in such matters, to the authorities who treat on these occult subjects; but I may inform them, *en passant*, that unless the nostrum be used with judgement, it is quite as likely to deceive as to relieve, not only in acne, but in every other cutaneous or general ailment; though the same remedy, properly and seasonably applied, may be amongst the most useful and beneficial.

It sometimes happens that we may have succeeded in the removal of acne, particularly acne rosacea, but that a degree of redness remains on the end of the nose, or on one or two spots on the cheeks, which on examination is not found to be inflammation, but a dilated state of the minute cuticular vessels; there are two ways of getting rid of this disfigurement, both of which I have constantly found successful; when the vessels are very small and numerous, not appearing to be nourished by conspicuously large trunks, the best plan is to paint them over very lightly with nitric acid, of the pharmacopœia strength, which is to be immediately blotted off with bibulous paper; by this mean a blister is raised, and the cuticle detached after a few days, when it will be found that the morbid state of the capillaries has disappeared, or that they have so much contracted, that a second application at the end of a fortnight is all that is required. The acetum cantharidis may also be used in a similar manner though it is not so effectual. The second method has the same object in view, though the mode of its accomplishment is rather different, and it is only applicable when the red portions of integument appear to be maintained by the influx of several larger capillary trunks—a morbid condition, which at the end of the nose is exceedingly common. The plan I adopt in such instances is to divide each trunk in succession with the point of a fine lancet, and as the blood flows very freely, I restrain it by means of a small ring of steel or silver, which is mounted on a stem, an inch or two in length, and fixed into a handle at right angles; by this means I can as it were insulate the little wounded point, and arrest the hemorrhage, whilst the blood can be sponged away and the incision exposed, so that a piece of lunar caustic the size of a grain of sand can be introduced into it, by means of a probe with a flattened extremity, on which it has been previously made to adhere; this at once stops the bleeding and obliterates the vessel, whilst it produces no disfigurement, beyond a temporary black spot that may be covered with court plaister, or the blackness may be removed, by wetting it with a solution of iodide of potassium; I can assure you I have cured numerous red noses by this simple procedure,—which I may mention is applicable to the removal of small nævi and the congenital red marks called *Araneæ* (from their resemblance to a red spider, with its legs outstretched. The small mounted ring I am now holding, and which I have ventured to call, "*The Ring Styptic*;" was made by Lings of Jewin-street I will hand it round; this little novelty in surgical apparatus, you will also find a most useful agent in arresting bleeding from leech bites, until a grain of caustic can be accurately applied as already mentioned. I have also used it with advantage, in removing cutaneous tumours of various kinds for surrounding a troublesome bleeding artery till it could be secured the size of the ring may be varied, but I prefer it no larger than a quarter of an inch in diameter for general purposes; but I can imagine such a contrivance useful under a variety of circumstances requiring surgical interference, which it would be quite out of order to discuss at this moment—amongst such, are deep wounds of arteries, whether the result of accident, injury or surgical operation. I fear you may consider this somewhat trifling, but happily, you have no red spots on your faces, otherwise I am sure you would not fail to attach sufficient importance to observations which might point to a remedy for so suspicious a disfigurement.

I will not however detain you longer on such points but briefly recite a case or two, in illustration of my observations on the treatment of acne, and I shall choose those patients from whom the models are taken as far as they go. I can scarcely think it necessary to adduce an example of acne simplex in its first stages, as many amongst you will probably have witnessed this disease in your own persons—I shall therefore in the first place relate an instance of *acne simplex inveterata* which is illustrated by the model 6100—that of G. Wihelm, a German tailor, residing in Batty-street, Commercial-road. The age of this patient was 24, and he had suffered six or seven years from his disease. He was admitted on the fifth of September last, and the model was taken in the beginning of November, his condition having somewhat improved; but he was a timid and somewhat refractory patient as indeed you would judge from the impress of his features on the cast, which in other respects does not very well represent his condition—a circumstance arising from the necessity of using much oil in taking a mould of the face, which of course obliterates the minute markings of the cuticle. This was a case of *Acne Simplex Inveterata*, and was a very good example of the disease. The tubercular pimples varied from the size of a common pins head, to that of a large bead, and they were in every stage of their progress, from the simply enlarged and loaded follicle, to that of suppuration and cicatrization, whilst the skin had the peculiar greasy sallow hue, so characteristic of acne; and a violet vivid tint not only surrounded the larger vari, but marked the site of the cicatrices when the healing process had been accomplished. I have no doubt that this patient was a victim of practices, to which it is not necessary I should allude more distinctly, though I failed to elicit a confession of the fact. I could discover no other cause for this inveterate affection which covered the face, neck, and shoulders, and seldom maintains its violence to the age at which this individual had arrived, (twenty-four); there was some degree of constipation, and much languor and lassitude in the case, though the pulse was full and strong, and the temperament sanguine. The treatment consisted in the administration of aloetic purgatives, in combination with the use of iodide of iron, in the use of a weak mercurial ointment, at bed time to the affected parts; and a spirituous lotion in the day, which contained the Hyposulphate of soda decomposed by sulphate of alumina. The improvement was very slow in this case, from I fear, a continuance of the exciting cause alluded to and the patient is still in attendance, and takes the sulphur fume bath occasionally which has appeared much to benefit him, so that at the present time, his disease presents no very marked evidence of its former inveteracy though it is not cured: as the bowels have continued obstinate, an alterative mercurial has been prescribed from time to time, and he has latterly taken the sulphate magnesia and sulphate of iron in small doses twice or thrice a day, and used the bichloride of mercury in creosote water, as a lotion. I should mention that this patient was directed to wash his face with oatmeal and avoid soap and to enlarge the openings of the diseased follicles and squeeze out their inspissated secretions, whilst the suppurating vari were opened with a lancet, when a soft point in their centre indicated the presence of pus.

Another case of acne simplex, which presented sufficiently marked characters of the variety termed by WILLAN *Indurata*, the face only being affected, is that of Sarah Patts, *æt.* 21, admitted October 17th 1845, having suffered three years; as there was amenorrhœa and leucorrhœa in this case, the tincture of sesquichloride of iron in infusion of quassia was directed, an ointment containing white precipitate was used at bed time, and a lotion of trisnitrate of bismuth, and bichloride of mercury during the day: all the suppurating points were opened with a lancet, and the curd-like contents evacuated, the face was well steamed over boiling water before going to bed and the ointment afterwards applied. The bowels were regulated by an aperient pill and the leucorrhœa moderated by an aluminous lotion, this young woman attended weekly, with progressive and marked improvement in the local and general symptoms, till the 28th of November, 6 weeks from her admission when she reported herself cured her face manifesting no remains of her disease.

The next case I shall recite is one of the species I have termed *A. Pustulosa.* Mary Tibbs, *æt.* 22, of Thomas-street, Brick-lane, became a patient on the 1st of December last, having suffered during one year and a half from her disease, which affected the nose, forehead, and cheeks. The pustules in most instances were quite insulated, though in different stages of their progress; a thin reddish scab covered some of those which had broken and discharged, others were filled with a straw coloured pus—a few exhibited a red spot of an irregularly angular shape, as though the skin had been forcibly scratched or torn off, whilst a certain number manifested mere slight conical red pimples the size of large pins' heads—a few of these pimples and other appearances were scattered over the body, between the breasts, in the hollow of the back, and on the thighs but they were neither so numerous or important as to attract the patient's attention, until enquiry was made concerning them. A considerable degree of itching attended the acne, but there was no derangement of the health—the complexion was pale, save in the vicinity of the diseased spots, where a brighter redness than is witnessed in other forms of acne was observed, which also extended further round the face, and was most remarkable in the few situations where the pustules had become confluent. An acidulated solution of sulphate of magnesia, a few sulphur vapour baths, an ointment containing white precipitate of mercury and precipitated sulphur, and a spirituous lotion holding borax in solution, have very speedily subdued this disease, so that the patient presented herself to me on the 6th of this month, five weeks from admission, and I wrote *well* against the date of her attendance; a result, I may remark, which in this species of acne is very rarely attained in so short a time: indeed as I have before observed the contrary may commonly be prognosticated. As a case of this rather uncommon form of acne presented itself yesterday in the person of a youth, aged 19, living in Shoreditch, I directed him to attend here to-day for his medicines; and have now the pleasure of introducing him to your notice before any means have been adopted which might modify the characteristics of the disease; it has had possession of his face for about four months, and you will, I think, observe considerable distinctions existing between it and acne simplex: the most remarkable is the greater degree and acuteness of the inflammation, as evidenced not only by the florid redness and heat of the parts, but by the nature of the suppuration which you observe in many points, whilst the tubercular character of acne is very much lost—nothing like maggot pimples or indurated collections of sebaceous secretion existing in any of the follicles. In addition to this much itching exists, and yet I think you will agree with me, that the complaint is neither porrigo, impetigo, or scabies, but that it has all the characters of a true acne, a fact which its obstinacy and duration will not fail to verify. The model, marked 6421, of acne rosacea was taken from the next case, to which I shall briefly direct your attention: it is that of Maria Wood, aged 29, residing in George-street, Whitechapel; she was admitted on the 27th of last October, having suffered four years from acne rosacea. You will perceive that this case commenced at the period the varieties of acne I have hitherto mentioned, terminate. The condition of this patient is tolerably well represented by the cast, but the complexion is not pourtrayed, as it presented a yellow bilious aspect arising from hepatic disease, which indeed was the probable cause of the acne; this patient stated, however, that she could assign no reason for the eruption, which commenced four or five years ago by a few red spots across the bridge of the nose, that assumed a florid and diffused redness after meals, particularly if tea or malt liquor were taken; small conical vari soon made their appearance on these vermillion spots, which were surmounted here and there by a flattened small yellow pustule, that shortly broke and discharged a little sero-purulent

secretion. A yellowish thin scab followed, until the healing process occasioned it to fall off, when a brownish tanned spot occupied its place; in the meantime the redness and tubercular eruption extended across the cheeks and upon the chin and forehead until the face presented the appearance shown in the model. On inquiry, this woman had a pain in the right side, increased by pressure under the cartilages of the ribs, and uneasiness was felt beneath the lower angle of the scapula, and on the top of the shoulder on that side: her evacuations were of a clay colour and irregular, mostly relaxed. I considered these symptoms sufficient indications to administer mercurials, and therefore directed she should take one sixth of a grain of bichloride of mercury in solution, with three or four drops of laudanum three times a day; a tepid bath for three-quarters of an hour, to equalise the cutaneous circulation, was ordered twice a week, and the local application of weak mercurial ointment with creosote at bed time; a sulphurous acid lotion being used during the day; no change was made in these remedies and measures during the three subsequent attendances of this patient at intervals of a week or ten days; the improvement in her health and in the appearance of the eruption was marked and progressive, so that on the 30th of November, five weeks from her admission, she returned thanks for a cure of her four years' malady and took a supply of an aperient chalybeate and the local remedies, which were to be used should any further occasion present itself. I must not neglect to remark, that every variety of acne is very liable to reappear, on the advent of the exciting cause, whether this be error in diet, visceral disease, or morbid habits of any kind; and indeed sometimes its repeated attacks can be referred to no obvious origin, but seem rather to be influenced by some peculiar idiosyncrasy, or habit, in the skin of the patient. Acne is especially a cutaneous disease, which torments the rich as well as the poor, and at the youthful periods of their lives, and in the conspicuous situations presented by the face, neck or shoulders, so that this disease will be more frequently brought under your notice than any other; although much deterred by a belief in its incurability, particularly in the form known as *acne rosacea*, which generally obtains, not only amongst patients, but the authorities who have treated on the complaint. Thus Bateman in his Synopsis, observes "The perfect cure of acne rosacea is in fact seldom accomplished, for whether it originate in a strong hereditary predisposition, or from habitual intemperance, the difficulties in the way of arresting the habit of body, are almost insurmountable."—*Bateman's Synopsis*, p. 402. Rayer and Cazenave have expressed similar opinions in their writings, but I am sure I can refer to the numerous cases recorded in the register of this Institution, and to the patients themselves, in proof that my practice has been more fortunate, indeed I am inclined to place acne rosacea where no hypertrophy of the skin has taken place, as amongst the most readily alleviated cutaneous diseases, a month or six weeks commonly sufficing for a degree of amelioration that patients frequently regard as a cure, though, may I beg you will not forget that it is not unusual for these parties to apply a second, or a third time for relief, as a relapse into their former habits, most commonly produces a return of the malady. It is surprising how frequently a predilection for malt liquors and salads, and a gratification of such tastes, can be traced as the causes of these returns, it therefore behoves the practitioner to place a patient on his guard on these points, when dismissing him. Relieved from the disfigurements of acnous complaints indeed, a carefully regulated diet, with a proper proportion of alcoholic stimulants in a dilute form, will be found to be the best adjuvant in the cure of acne, whilst a vigilant subsequent adoption of the same plan will prevent a relapse. I believe I have now, gentlemen, put you in possession of the best means with which I am acquainted for the treatment and cure of this disease, you will observe no great novelty in my remarks, nor are the poisons and irritants administered, which seem required by many affections of the skin, yet I cannot think, from comparing the success which very constantly follows the treatment of these cases, as I have advised, and the results detailed by authorities on the subject, that the plan recommended can be usually adopted; otherwise, my good fortune is in the ascendant, as I scarcely or never met with a case of acne rosacea, of however long standing and inveteracy, that was not cured or materially alleviated.

At a future period I shall have to speak of two very similar affections in their nature to acne simplex, when considering cutaneous tumours, these are the follicular disorders known as atheromatous tumours, and molluscum, but if you please we will defer their consideration until the occasion referred to, as, were it commenced at this time, I should be led into details that might destroy the unity and completeness which I am constantly endeavouring to accomplish, in presenting these cutaneous sketches to your kind attention; for the same reason, therefore, I shall not commence the subject of sycosis until next week.

THE NATURE, CAUSES, AND TREATMENT OF MENTAL DISEASES.

By M. PINEL, M.D., Member of the Academy of Medicine, formerly Physician to the Bicetre and Salpetrière Asylums, Author of the "Traité Medico-Philosophique sur l'Aliénation Mentale," "Medecine Clinique," "Nosographie Philosophique," &c., &c. Translated, with Notes, illustrative of some important Doctrines in Physiology, Phrenology, and Moral Education,

By Dr. COSTELLO,

Principal of Wyke House Asylum, Editor of the Cyclopedia of Practical Surgery, &c.

LESIONS OF THE SENSIBILITY AND SENSES.

These lesions, like others of the nervous system, occur in the state of exaltation (hyperesthesia of Andral); in the state of depression (anesthesia), and in a state of perversion (illusions, pains).

Exaltation of the Sensibility in the Organs of the Senses.

We see individuals whose sight is so sensitive that they cannot bear to look on bright light; they can see only in a feeble light. This affection often arises from long confinement in an obscure place. In others the exaltation of the sensibility of hearing renders the slightest noise painful. The sensibility with regard to smelling, presents also, phenomena still more curious: some highly nervous women are led to perceive odours and miasms which no one else can perceive, and can distinguish one person from another by the smell. In some persons this sense is so acute that they cannot bear the smell of certain animals, without producing great disorder of the nervous system. The cutaneous system may also become the seat, completely or partially, of very acute sensitiveness, in some cases exaggerated in one half of the body, and enfeebled in the other half. During this state of exaltation, mere pressure on the skin, or even the approach of the hand to touch it, produces shocks or painful ticklings. In our ninth case of general paralysis, we had exaltation of the sensibility on one side, depending on acute hypertrophy of the brain; under some circumstances this cutaneous exaltation comes on by degrees in consequence of chronic alteration of the nervous centres.

It may happen in the same individual, that all the senses may be very acutely morbid at the same time, producing a state of general suffering, fortunately rare. Such extreme susceptibility imposes the condition of living in a state of isolation and seclusion from every object that can affect the sight, hearing, smell, and touch. This physical condition has most unfavourable influence on the character of the patients: they become irascible, fretful, shed tears without motive, state that they are a prey to suffering they cannot account for, and all the sensations that render life happy are to them a subject of continual complaint and pain.

Their consciousness of the slightest atmospheric variations is very curious: they are aware beforehand, and with rigorous precision, of the slightest changes of wind, and of the state of weight or electricity of the atmosphere. This faculty of prevision, unknown in the ordinary state, depends undoubtedly on the exaltation of the general sensibility. This exaltation of the sensibility arises from various causes; it may arise from prolonged intellectual labour, from watching, excess, and the deeper passions of the mind; or it may follow from causes the very reverse of those; from inactivity, from the privation of any habitual excitant, as tobacco or poppy; a too severe or too prolonged abstinence in course of convalescence, may give rise to it. There are cases in which it does not arise in the brain, but from imperfectly performed functions of the life of nutrition, more especially from the imperfect accomplishment of the hæmatosis, which has a very remarkable influence on the nervous system. It might be assumed, that the more the hæmatosis was easy, the more molecules, rich in nutritious principles, would the nervous system receive; and, as a consequence, the more it would be excited; this is not the case, but just the contrary happens, and of this we may be readily convinced by observing the irritative influence which chronic and protracted diseases produce on the nervous system.

When this exaltation of the sensibility depends on a cerebral cause, our first indication is to combat this cause, employing at the same time warm baths and diluents. If it be the result of a defect of excitation, the patient's strength should not be reduced, as a debilitating regimen would only exasperate the symptoms; a regimen too mild may cause an excess of sensibility in the tongue and conjunctiva; if we are too tender with this sensibility, it would happen at last that nothing can be borne, which, by acting against it would deaden it gradually. Dry frictions should be used on the skin, gentle at first and progressively rougher, their effects should be seconded by cold sea bathing, pure air, sun, and muscular exercise, which can act directly on the blood; by substantial unexciting food, a moderate use of generous wine, and abstinence from tea, coffee, and liqueurs: preparations of iron and quinine will also be proper sometimes; these nervous pains are cured, as it were by a charm, by a drop of orange flower water or of ether. Narcotics are more hurtful than beneficial.

The treatment of these affections is often rendered difficult from the derangement of the digestive organs; but we are not to lay too much stress on the pains the patients complain of in the intestinal canal, as these pains are nervous. There are some individuals who feel acutely the pulsations of the heart, the circulation of their blood, the process of digestion, all these symptoms of exaltation of the sensibility may be classed chiefly with those of hypochondriasis.

II

DIMINUTION OF THE SENSIBILITY, GENERAL OR PARTIAL.

In whatever region of the body the sensibility is diminished or abolished, we must admit that the lesion depends on an alteration in the nervous cords, or centres governing this function. Lesions of the sensibility may be independent of those of the motility, as the faculty of motion is independent of that of sensation, although they are exercised in cords, and fasciculi, and centres, common to each other; for, though the anterior cords of the spinal marrow are peculiarly motory, and the posterior cords are peculiarly sensitive, they are not separated in the great nervous centres by a line of demarcation so precise as to prevent their being intimately connected; this structure explains how it is that the cerebral hemispheres, which should exhibit lesions of the intellect only, do also exhibit very decided ones also, both of motility and sensibility.

Abolition of sensibility is often the result of a direct injury to a nerve; a man had his wrist lacerated by the bridle of his horse, and sensibility was destroyed in the hand. The median nerve was injured, being flattened like a ribband, and adhering to the tendons. The nerves of the fingers were altered in texture, resembling ganglions. Andral mentions a similar case.

The cutaneous sensibility may be wholly or partially abolished; when the abolition is partial, it generally affects one side completely, while the sensibility of the other side remains natural or may be much exalted; the difference of the symptoms depending on the seat and extent of lesion of the sensitive cords.

We have seen in the œdema of the brain, and in general paralysis, how various are the lesions of the cutaneous sensibility; sometimes the limbs, certain regions of the chest and abdomen, the conjunctiva, or the schneiderian membrane are struck locally with complete insensibility. In others, the sensibility is extinguished gradually on one side of the body, and without any very apparent cause; or it is suspended for a time in the fingers of one hand, or in both hands and feet at once. A woman, who slept in the sun,

and who had a phlyctenous eruption on the skin, was attacked with insensibility in both hands and feet, at the same time, to such a degree, that she several times burned her toes without being aware of it. In others, the insensibility has shown itself in rings or circles, or in different parts of the body.

It varies also in duration, lasting only a few hours or days, or for months or years; it may disappear and then return, and pass from one part of the body to another; its attack may be sudden or gradual. A young man, who had a fracture of one of his ribs, perceived that his hip was insensible; the insensibility extended gradually to the limb, and then to the opposite limb, the trunk, and finally to the integuments. In the majority of cases, the attack is sudden, and from a lively emotion of joy or fright. But it is in hysteria and somnambulism, that insensibility exhibits its most singular phenomena; and these also are the cases, in which the most experienced physician is liable to be deceived.*

III.

PERVERSIONS OF THE SENSIBILITY.

1.—*In the Organs of the Senses.—Illusions.*

We know that in hallucinations, the action is confined to the brain; in illusions, on the contrary, it is in the extremities of the nerves that the sensibility is perverted, and, as the effects of this reaction are subjected to the influence of the insane man's ideas, they give rise to continual errors in the nature and cause of his sensations. A man in health is subject to illusions of the senses, but his reason corrects the error. This is not the case in the insane; and if we consider that the perception of a sensation requires three conditions—integrity of the sense that receives the impression; integrity of the nerve that transmits it; and integrity of the brain that perceives it; we shall not be surprised at the frequency of illusions in insanity, in which always one, and often two of these conditions are wanting. The sounds that a maniac hears are those of a friend who is coming to his relief, while the melancholic imagines he hears the cries of his enemies, or of the police in pursuit of him; these are illusions of hearing.

Illusions of sight are no less frequent, producing resemblances that give rise to excitement, fear, indignation, and fury. A lady imagined that the wife of a physician was her rival, and wanted to attack her whenever she met her. A young man, labouring under erotic delirium, imagines that he sees in an opposite house the female who constantly occupies his thoughts—his manner, gestures, and countenance, show the vivid pleasure this illusion gives him; he is compelled to return into his own house, and with difficulty convinced of his error. He is at the same time under the influence of strong religious ideas, and imagines that his servant is Voltaire, he speaks to him in abusive language, telling the infamous Voltaire to leave his presence. A female, labouring under hysteria and mania, watches constantly at her window, and every single cloud she sees, says it is Garnerin in his balloon, and she calls him in a loud voice.

It is to illusions of sight that we must attribute the great pains that some insane persons take in collecting stones, pebbles, and pieces of glass, imagining them to be objects of value, and this, too, is the cause that prevents them from reading or writing, as they see the letters riding over each other.

The illusions of smell and taste are also well marked in the insane; in the beginning of their disease, they generally refuse to take food in which they find a bad taste, or a particular smell, and hence their prejudices against the servants, and their fears of being poisoned. These illusions often depend on disorder of the digestive functions, and are soon dispelled. They have nothing of the obstinacy of the melancholic, who resort to a refusal of food as a means of suicide. A patient who was ordered an infusion of digitalis, said it was urine they gave him.

The illusions of touch of the skin are still more remarkable. The skin of the patient is often dry and earthy, and at other times so sensitive, that it cannot be touched without producing a painful impression. There is a patient at Charenton who cries out when he is touched, saying "you hurt me—don't strike me." A furious maniac, whom it was found necessary to place in a cell with straw alone, arranged it in a circle, placing himself in the empty space in the centre, he was observed blowing in every direction, and uttering cries of distress, believing that each straw was the bill of a bird of prey, that he was endeavouring to keep from attacking him.

Visceral illusions are amongst the most curious phenomena of the lesions of organic sensibility; to them belong the errors of the hypochondriac, and of many other forms of chronic delirium, both in men and women. The brain, independently of the impressions transmitted to it from the five senses, receives others from the internal organs, the lungs, heart, digestive organs, and especially from the organs of generation. In the lungs, the influences of phthisis give rise to feelings of happiness and of buoyant hope; organic lesions of the heart predispose singularly to moroseness, sudden passion, and to gloomy anticipations.

In the intestinal organs, these morbid reactions become veritable illusions for the insane: a melancholy patient complained that she had a live animal in her stomach; she was suffering from a cancer. Another believed she had a regiment in her belly, and could feel the soldiers fighting with each other, and wounding her with their arms; she was subject to intestinal pains. An insane patient at the Salpetriere, *the mother of the Church*, believed that she carried in her belly all the personages of the old and new Testament; she heard and felt the blows of the hammer of the crucifixion. The autopsy shewed an inflammatory adhesion of all the viscera to each other. A maniac used to strike his knee with his fist violently, believing he had a thief in his knee.

The most extraordinary illusions amongst insane females are those that arise from the generative organs; they experience all the sensation of the union of the sexes, think themselves in the arms of a lover, or a ravisher. It is not uncommon to find such persons with eruptions, ulcerations, or cancer of the neck of the womb. A patient feels during her sleep some one get into her bed and tempt her; she feels horrified at his proposals, she thinks herself lost, dishonoured, because it is said that she yielded; her conclusion on this point is too strong to be shaken.

The treatment of illusions of the senses may require the use of physical remedies in order to calm, or to remove the lesions that excite the illusions. Sometimes applying the hand on the eyes of a furious patient, has calmed her—she believed that frightful objects were passing before her. The same effect is not so easily produced in visceral illusions, and a clue to the proper treatment can only be sought in the study and appreciation of the organic cause on which they depend.

2.—*Perversions of the general Sensibility.*

Observation shews that there are cases in which the perversion of the sensibility is confined to certain organic instincts, prompting to the use of certain elements or liquids. The perversion may proceed to such an extent as to shew itself in a horror of liquids as in hydrophobia.

The horror of liquids alone may constitute a disease. An invincible repugnance for drinks is observed in hysteria, in dangerous fevers, in inflammations of the œsophagus and pharynx, and it is one of the symptoms, peculiar to rabies, which therefore is improperly called hydrophobia.

3.—*Perversion of the sensibility with pain.*

There are circumstances in which this pain is the sole malady; it may be fixed in a nervous trunk, and follow its chief ramifications, or it may have no fixed seat, manifesting itself in different parts of the body. In the first case, we have neuralgia; in the second, it manifests itself in the head, body, or limbs.

CAUSES OF CEREBRAL DISEASES.

—*Predisposing causes.*

These are hereditary, the critical period of life in women, the progress of age, parturition, certain dispositions, certain conformations of the brain, according to Gall, and the influence of public events.

The brain, of all the organs, is certainly one of those in which hereditary predisposition manifests most strongly its unfavourable influence. It is by heredity that almost all the cerebral affections are transmitted, and this is more marked in the higher, than in the lower classes of society. The first families in France have thus become extinct, or have at last reached a degree of intellectual degeneration inevitable on account of their position compelling them continually to form alliances limited to the circle of a few privileged houses. The jews, whose religious prejudices have compelled them to intermarry with their own people for ages, present the same degeneration, especially in Germany and Poland, where they are kept apart from the general community. In France, this state of isolation can scarcely be recognized.

It is not uncommon to see amongst the insane at the Salpetriere, two sisters, the mother and daughter, and sometimes the grandmother.

Heredity bears a twofold evil, in being often not only the sole direct cause of cerebral disease, but of also disposing the brain to be more readily affected by the bad effects of other existing causes. We thus see several members of the same family becoming insane under the same circumstances and at the same age. A Swiss merchant had two sons and a daughter, that successively became insane at the age of nineteen. There is a family at Nantes of seven brothers and sisters in a state of dementy. If exact information could be obtained in hospitals we should be able to acquire a certitude that heredity is a still more frequent cause than it is supposed to be at present, not only of insanity, but of apoplexy, epilepsy, cerebral fever, and of all the other chronic or acute disorganizations of the brain.

Hereditary insanity shews itself early in eccentricities of disposition, singularities of taste and habit, a strange and always ill grounded manner of acting and reasoning, an extreme readiness of contracting likings for the most frivolous things, an irascibility and obstinacy. In some females, it is sometimes shewn in an extravagant taste for accomplishments, works of imagination, or for serious studies uncommon in women.

It must not, however, be inferred from hereditary predisposition, as regards all nervous affections, that the children of parents so affected must necessarily be attacked in the same way, especially when the predisposition is derived from the father, or mother only. The children may escape its influence, if they be not exposed to similar conditions of excitement. Education and moral training, modify favourably the physical predisposition, and this is accomplished by teaching them from their tenderest infancy, to conduct themselves well, and by placing them in the world, in positions, where they may have the certainty of a certain and moderate livelihood, free from the hazards of speculations for place, or fortune.

In the majority of cases, the predisposition is so unfavourable, that neither care, nor education can avert the nervous affection, even under the most favourable circumstances. In epilepsy, and suicidal mania, so unfavourable is heredity, that it rarely fails to manifest its influence. In one family, a mother and three daughters have committed suicide.

In women, the consequences of parturition predispose singularly to mental alienation; in this state, they become highly impressionable, and sometimes a slight emotion brings on delirium. It may even at last have such influence over the cerebral functions, that every fresh accouchement brings on an attack of mania, without any other cause; women who have had five or six such attacks, are not uncommon at the Salpetrière.

The critical period of life in women, also predisposes to cerebral, hysterical, and convulsive affections. At this period, while the equilibrium of the functions is disturbed, the desire of pleasing seems to be augmented, while the charms of the person are impaired. It is then, that spite and jealousy, drive well bred women into fantastic devotion, while those who have not received an education, become addicted to drunkenness. The progress of age too, by weakening the springs of the system, predisposes the brain to all the physical, and intellectual decadences that afflict the aged.

It is to certain dispositions of the mind and character, more especially that we must attribute the ready development of the numerous diseases of the brain: such as the natural defects of a feeble intellect, influenced by bad instincts, impetuous passions, intellectual labour confined to a small circle of speculations, ideas on religion, or politics, the anxiety of business, startling public events, which stir up and change the prevailing ideas of a people. It would not be difficult to discover in the records of public and private establishments, from 1789, down to our own times, the characters of the delirium, peculiar to those different periods.

We have just mentioned dispositions of character as a natural cause of several cerebral affections, of those especially distinguished by perversion, or exaltation of the instincts. Of all these causes, the most powerful are those which depend on the conformation of the brain itself, and the anormal preponderance of some of its parts over others. It is on such preponderances of the cerebral mass in the anterior, lateral, superior, and posterior regions, and the observations to which they have led, that Gall has been enabled to found his doctrine, thus localizing the developments of man's intellectual and moral nature, by reference to the organic dispositions of the several parts of the brain.

It has been remarked, that in the brain, as on other organs, the development of one part of an organ, is almost always effected at the expense of the rest of the organ: thus we see persons, in whom the back of the head is largely developed, while the forehead is flat or retiring. Others on the contrary have the frontal region large, and the back of the head flat; in others, the head rises like a sugar loaf, while the anterior, lateral, and posterior regions are flat, while in others, the lateral regions alone are developed. The largest development of the encephalon, which we find in the busts of Plato, Montesquieu, Haller, Byron, Cuvier, &c., is the rare one that takes place in all the portions of the brain at the same time, and in the proportions of that organic equilibrium, of which an ideal type is represented in the head of the Apollo Belvidere. When this development occurs in only one region, the developed portion must of necessity exercise a predominance over the functions of all the rest, and it is these influences of the nervous mass that we must recognize, as predisposing causes to some of its most important disorders.

Functional, or Moral Causes.

Causes that lead incessantly to derange the organization of the brain, by the very exercise of its functions are the most frequent, not to say, the only ones that produce its most serious maladies. The records published by Pinel, Esquirol, and some English and American physicians, leave no room to doubt on this point. In reading the numerous cases of insanity, to be found in authors, one is struck with the proportion arising from moral causes. It amounts almost to a popular axiom. The first question we ask an insane person, if he be capable of answering, is whether he has had troubles, anxieties, or sorrows? And is it not at the time of life, when the intellect is in full power, and the passions are at their greatest energy, that we see developed the most alarming nervous disorders? In infancy and old age, physical weakness and carelessness, blunt all those distresses and emotions, which in mature age so violently disturb the brain.

It is often difficult to obtain a full avowal of their secret sorrows from women, and young girls; yet they often suffer torments and deep distresses, which they will never confess. How many young persons there are who love in secret, who, deceived in their hopes and confounded with shame, lose their reason, without daring to make any avowal to their family? Then, the secret jealousies, the novel reading, and the chimeras, with which a mind still free from distrust is filled, the sad reality which soon dispels them; all these causes act silently in young women, from an early period, giving rise to insanity, epilepsy, and hysteria, and it is often only long after the occurrence of disease, that chance reveals the true cause.

Moral causes may be said to be as various, as the acts of the understanding itself, as in general they are but an exaggeration of its functions, and we call them on this account functional causes. They are made up chiefly of whatever agitates the mind suddenly, surprise, fright, anger, joy, sorrow, jealousy, hatred, or whatever wounds a man in his inclinations, affections, ambition, pride, or in his religious or political ideas. Social position, and education, besides modify these first causes in a thousand ways; in the lower classes by bad conduct, debauchery, harsh treatment, misery, or dissipation without care for the morrow. In young women, by the alternative of shame or poverty, crossed love, a disappointment in marriage, or exaggerated ideas on religion. In persons of weak mind, this religous tendency combined with a disposition to love, gives rise to those extatic loves for God, a Saint, or the Virgin, which so readily degenerate into melancholy fears of demons, and of future punishments. In the upper classes, disappointed ambition, love, vanity, the excesses of study, and reverses of fortune are the commonest causes of all kinds of nervous affections; some of them act at once, producing suddenly symptoms of delirium, convulsions, or paralysis: such are fright, violent anger, sudden loss of money; while others act silently and slowly. Sadness, jealousy, religion and political ideas alter the cerebral functions only by long repeated action. In mental alienation, the delirium is thus established gradually, becomes concentrated, and exhibits itself at last when it can no longer be controlled by reason.

In all these acts, it is the brain therefore that alters itself by the exaggeration of its own proper faculties; all tumultuous and passionate movements, all concentrated and exalted ideas, are but the first effects of a nervous superexcitation, which passes easily into a morbid state, and which by means of sympathetic reactions is extended to the whole economy. Thus the general expansion from joy, the epigastric constriction from sorrow, the palpitations of the heart from fright, and the muscular exaltation from anger, are but the indirect result of nervous effects, which produce the most profound disorders in the brain.

III.

PHYSICAL CAUSES.

The predisposing causes from being best known and most readily appreciated, are exposed at great length in works on nervous diseases. On this account we have bestowed on them a succinct indication only. As regards physical causes, we must proceed differently, as they embrace almost the whole of the general and pathological anatomy of the brain; then history and learning on the symptoms are still sufficiently obscure and contested to require our dwelling on them at some length. Moreover to seek out and describe those physical causes, would be merely to seek out and describe the maladies themselves, and the lessons on which they depend. But in the diseases of the encephalon, we may confidently repeat that the pathological alternations present general and determinate characters, and in the present state of our knowledge, our aim is no longer to show identical lesions for identical diseases—that there are for instance, particular lesions for insanity, epilepsy, and others for general paralysis. This would be pursuing chimeras which the facts disprove, and will continue to disprove more and more. In all the cerebral affections, acute or chronic, the nervous pulp undergoes successive deformations which are now capable of being reduced to general laws.

But the inevitable consequence of this first truth is a result that we have already stated, viz., that it is not according to the nature of an anatomical lesion, but as it interests a given order of fibrous fasciculi, or the centres composing the encephalon, that we can discover the difference and special nature of maladies. According as these fasciculi and centres are intellective, motory or sensitive, as they are more irritable in certain parts of the cerebro-spinal axis than in others, as their lesion is isolated, or complicated, we shall have according to the duration, depth, and extent of the lesions, diseases very different from each other, or complicated with symptoms directly bearing on the functional lesion, even though the anatomical characters of the alterations be the same, and in places varying greatly from one another. It is in this sense that we must understand what is meant by the word *seat* in the study of cerebral affections. Diseases of motility may be seated wherever there are motory nervous fibres; diseases of sensibility, wherever there are sensitive nervous filaments. In the brain, these two orders of nervous fibres concur in the formation of the hemispheres, which are centres for the sensations. It is for this reason that intellectual lesions may be complicated with lesions of the sensibility and motility, in the different alterations of which the brain may be the seat.

ORIGINAL CONTRIBUTIONS.

ON ETHNOLOGICAL SCIENCE IN ITS RELATIONS TO MEDICINE AND PHYSIOLOGY.

By Richard de Gumbleton Daunt, M.D. (Edin.) Member of the Faculty of Physicians of Rio de Janeiro, and Member of, and late honorary Secretary to, the Parisian Medical Society, &c.

"Plus j'ai voyagé, plus je me suis convaincu que les *races* sont le grand secret de l' histoire des mœurs L'Homme n'est pas aussi educable que le disent les Philosophes. L'influence des gouvernements et des lois est bien loin d'agir aussi radicalement qu'on le pense sur les mœurs et les instincts d'un peuple; tandisque la constitution primitive, le sang de la race, agit toujours et se manifeste apres des milliers d'années dans les formes physiques et dans les habitudes morales de la famille ou de la tribu. Le genre humain coule par fleuves et par ruisseaux dans le vaste ocean de l'Humanite; mais il n'y mêle que bien lentement les eaux, souvent jamais, et il ressort comme le Rhone du lac de Genève avec le gout et la couleur de son onde. Il y a la une Abime de Pensées et de Meditations."—*Extracted from "M. de la Martine's Voyage dans l'Orient."*

When studied with ever constant reference to the grand primordial truth of the unity of origin of the human species, the doctrine of races is one of the facts most fecund in its applications, and most useful in unravelling the mysteries, of the various destiny, &c. &c., of nations and empires, which the whole range of philosophy can offer. In this paper, I shall first remark, on the fact of the existence of races, and next, on the utility of the knowledge of this truth to the practice of medicine.

It cannot be doubted, that the several races into which the human family is divided, existed at the earliest historical period, in as full contrast as at the present moment; some of them, even then, possessing a stupendous development of intelligence and some progress in the arts, while others were sunk in all the barbarism which characterizes in our day the native of Tasmania or New South Wales. Were this not so, the Negro contemporary of the Pharaohs' would not have left his effigy on their sculptured monuments the analogue of the Negro of our own times. Had time been, an indispensable condition for the development of the human being from a supposed imperfect and savage life, how comes it, that a civilization so remarkable should, at the most early known epoch, have appeared in some races, while other contemporary races, with the aid of four thousand years, are still as in that early day? Again, if climate really solved the question, why should the Cape of Good Hope

which, as from personal observation I can testify, enjoys a delicious and temperate climate, be the habitat of the type of the Melanien branch of the Æthiopic variety—the most degraded form of man, the Caliban of his kind, the hideous and degraded Boschjesman—who possesses in their extremest degree, the anatomical peculiarities of the Ethiopian,—the oblique teeth, the imperfect utterance, the removal of the occipital foramen from the centre of gravity of the cranium, the inclined pelvis and inferior extremities, the posture between the vertical of the Indo-germanic man and the oblique station of the Ourang? In their incapacity to continue to exist as a race in an enslaved condition, the Melanien tribes, however, differ from the Negro and approximate to the American native. How, if external causes were as all-powerful as is supposed generally, could it happen that the race, most favourably situated in regard to external influences of all those of Africa, should be exactly the most degraded and unreducible by civilization? The learned Bishop of Melipotamus, has the following passage which shews him to be inimical to the idea of a primary state of barbarism common to *all* mankind. "Truly there is a sap in nations as well as in trees; a vigorous inward power ever tending upwards, drawing its freshest energies from the simplest institutions, and the purest virtues, and the healthiest moral action. While these form the soil in which a people is as it were deeply rooted, its powers are boundless; and as these alter and become exhausted, it likewise will wither and decay. Assuredly there was a vigour in the human mind, as compared with ours, gigantic, when the Homeric songs were the poetry of the wandering minstrel, when shepherd chiefs, like Abraham, could travel from nation to nation, and even associate with their kings, and when an infant people could imagine and execute monuments like the Egyptian pyramids, and if of nations we may so speak, what shall we say of the entire human race, when all its energies were in a manner pent up in its early and few progenitors; when the children of Noah removed but a few generations from the recollections and loss of Eden, and possessing the accumulated wisdom of long-lived patriarchs, were marvellously fitted to receive those strange and novel impressions, which a world just burst forth in all its newness was calculated to make; yea, when they themselves, an infant race, struggling on one side against the ravages of the late disaster, and on another against the luxuriancy of its renovating influence, must have felt within themselves a boundless energy in thought and action, a quickness of apprehension, a richness of contrivance and a might in execution equal to the crisis, and such as later generations could never want." He quotes also from Schlegel the following passage as combating the doctrines of Helvetius and others. "The reflection that nature, or rather its author, will place his creatures in the state for which He intended them, that, if man were formed in body and endowed in spirit for a social and domestic life, he can have been no more cast originally into a desert or a forest, savage and untutored, than the sea-shell can have been produced on the mountain top, or the elephant been created amid the icebergs of the pole; this reflection must exclude the idea that the savage state is any but a degradation, a departure from the original destiny and position of man." Anthropologists have singularly passed over these subjects in the generality of cases: were it not so, physiological writers would not rest satisfied with speaking of five divisions of the human race; and by physicians they have been almost wholly overlooked, except in so far as regards "temperaments," which is one position from which the physiological differences of races may be brought to bear on medicine. The idea of the five divisions, Caucasian, &c. &c., is utterly insufficient even in Europe, we still find numerous examples of races possessing most striking dissemblances, though living under climates little differing, and possessing them now, just as markedly and no more so, than at any period of which we have historic-knowledge:—thus the Latin Colonist of Wallachia, or the very primitive Szeckler of the Carpathians, driven to his present abode on the first appearance of the Roman legions in Pannonia; the peasantry of the Graubunden, still speaking the language of the Troubadours; the Irish of Connemara; and the German family, differ most intrinsically from each other, have done so immemorially, and will continue so to do. But not alone does the Caucasian variety offer these examples, the Ethiopian also does so, the sub-variety of the Melaniens—"Boschjesman," already mentioned, the Kafirs, the Normans of Africa, the Minas or Gold Coast Negroes, and the Monjol Negro, are all distinct types:—this last named negro, has often scarce quadrupedal instinct; he remains often during a long life, in the midst of other blacks all speaking Portuguese, and at its close, he will be found to have acquired but the words which express the first and most simple wants. Were I illustrating in detail the many differences which remove among themselves the Negro tribes as wide apart, as the whole Negro race is from the Greek or Norman, I might remark on the commercial tastes of the Negroes from the Guinea coast, which makes them invaluable as quitandeiros or market men; their impatience under slavery; their possession of the art of writing, apparently, a rude Arabic character; the greater influence which Mohammedism exercises over their religious belief, than over that of the other tribes; and the facility with which, when in numbers, as in the province of Bahia, they organise themselves into formidable secret societies. Then of the Kafirs, how much might not be told? a race, daring, cunning, faithless, addicted to plunder, but yet of great capabilities, at present used for the purposes of different rival missionary societies,—irreducible to slavery, but themselves slave holders. Their chiefs have often been as famous as many conquerors of the old world, and they, about thirty years ago, possessed a warrior-prophet, who had nigh become the Joshua, or Mahommed, of South Africa. The name of this remarkable man was Mokanna, or the Lynx; in 1819 he delivered himself up to the English, but soon after escaped with four companions; some of the party were drowned, and the English Governor insists that Mokanna was among the number, a fact strenuously, and with some show of truth, denied by the Kafirs, who, (like the Portuguese peasant still looking for the return of Dom Sebastian from Paynimry, or the Styrian who expects one day to see the Emperor Frederic Barbarossa issue forth from the cavern where he and his court are still spell-bound,) believe in a future reappearance of the Lynx; and from time to time the whole Cape frontier is thrown into excitement, by the arrival of wandering parties from the distant interior, who, ensure themselves a favourable reception by delivering pretended messages, promising aid and his presence among them, from the lost prophet. Yet, this tribe of Negroes was originally, a native of the worst parts of Africa, and is but an intruder of a very recent date, into the more favoured regions of the Southern extremity of that continent, from which, much more than the Dutch colonists, it has extirpated almost wholly the legitimate inhabitant. This, is satisfactorily proved, by Lieut. Donald Moodie, R.N., in his edition of the records of the Cape of Good Hope Government, since 1652, in so far as regards its relations with the coloured Tribes; a work of high interest, as the only authentic record of the mutual influence of the white and coloured races when brought together in the colonial world. I might also dwell on the wide difference between the scarce articulate language of the Hottentot, and the so much more perfect languages of the tribes of the great Ichnana family, which Doctor Adams of Cape Town, endeavours to prove are closely allied to the Indo-Persic tongues. The differences in the physical form and relative development of the various elementary parts of the body, among the various European families, does not require illustration, but, to most readers it will be a new fact to hear, that among the Negroes proper, the races I have already named, and many others of which I might speak, differ among themselves as markedly, as does the noble Magyar race of Hungary, from the ugly and ill-made peasant of those parts of Germany, where relics of the great Hercynian forest remain, and where the German type is to be found in its greatest purity:—thus, the Minas, the Kafir, Negro, those from Loango and Angola, present well raised brows, Roman or Grecian noses, an erect bearing, shewing a centralisation of the Cerebro-rachidian system, and the opposite, in all points, to the physique of other tribes, as the Monjol, and those which come from the interior, to embark at the embouchure of the river Congo, in whom the predominance of the vegeto-mucous organs, over those of the nervous system of relation, is such, as almost to prevent the action of the latter. The Ethiopian division, gives in a word, examples of races which occupy a similar place to the Greek and Norman races, and others also, in whom, as in the purer Saxon races, "*c'est le Boeuf qui l'emporte sur l'ame.*" Again, I have ever remarked a better physical development and more exalted moral nature among the upper classes of any tribe, who, through the fortune of war become slaves, than in the *tiers état* of the same tribe, whom hereditary slavery had endued with the *morale* and even the language of the muscles, which we find among every enslaved people, and which Bulwer Lytton, in his character of the Jew, in the Siege of Granada, has admirably succeeded in painting. This last class really view with delight their transfer to the ownership of the white by their native hereditary master, and hail it as a sort of promotion. In all the tribes, I find an inferior physical development, and a vitiated moral disposition to go hand in hand; and a curious instance of this, is the powerful muscles of the lower jaw, observed in those tribes, whom their fellow captives accuse of cannibalism.

Now, all which precedes, has valuable applications in medicine—leaving out of view facts to be drawn from European observation, such as that a Scot of the Lowlands will take two ounces as an ordinary purging dose of sulphate of magnesia, while, for a French adult half an ounce will produce in general, the same effect—it is in the treatment of native Africans, that we ought ever to keep in mind the race; for the more degraded is the tribe to which they belong, the less vital reaction appears, the disorganising agency of disease being so much the greater, and the vis medicatrix naturæ affording the less assistance to medical treatment: and while depletions or depressing medicines are badly borne, stimulants and strong warm purges are highly needed, the latter to free the actively secreting mucous intestinal membrane from its slimy coating, and the often engorged state of its vessels. The higher tribes may be treated with few modifications, as may ordinary whites in the same circumstances, and the mortality among them is much less than among the inferior tribes; in these latter, the incapacity to struggle with disease, and the listlessness shewn under it, are instances of the force, which the sentence of subjection to the blighting agencies of this material universe, imposed on man at the fall, still exercises over them; while other races have advanced far in their reconquest of external nature, and their power of conforming their habits, &c., to the external standard of its immutable laws. The diseases of the native African are chiefly those produced by terrestrial and planetary agencies, and affect almost exclusively the mucous and dermal tissues, and the blood; and here I may be allowed a criticism on Smollett, who, in his "Rhoderic Random," making his hero take medical charge of a slaver, from the Gold Coast to the Antilles, represents a considerable mortality from *putrid fever*, as having occurred among the negro passengers; from which expression, if he means us to understand a typhus produced by animal poison, I certainly strongly doubt the probability of such an occurrence, universal experience shewing that under the circumstances where whites would be attacked by typhus, as it existed in the middle ages of Europe, or as it is still found among the Irish or Hungarians, the negroes and those other tribes, who, receding much from the Georgian or Grecian type, are endued with less vital cohesion of tissue, are attacked by virulent dysenteries, and the whole train of scorbutic and other primarily atonic diseases.

Another interesting application of this subject offers itself, which may be found fruitful: It is, that perhaps certain discrepancies in the history of cases and difficulties of theory, as found in the Hippocratic books, with what is observed at the present day, may in this way be explained; for example, in the case of crises and critical days, now, confessedly a doctrine not of so self-evident a nature, as it seemed to the Grecian physicians, may it not be, that among a race so elevated in the scale of the physical and moral hierarchy of man, all the vital actions had a natural perfection, and force and harmony, which, in other races, and under more complicated modes of existence,

they have ceased to possess. I shall not now pursue further this idea, nor the many co-relevant ones, but conclude in the forcible phraseology of C. Lamartine, that, "Il y a là une abime le pensées et de meditations."

City of Campinas, province of San Paulo, Brazil, February, 1846.

HOSPITAL REPORTS.

KING'S COLLEGE HOSPITAL.

Case of Trismus.

Reported by HENRY SMITH, ESQ. House Surgeon

Elizabeth Croose, aged 25, unmarried, came to the Hospital on the 3rd of July, with the following symptoms; her teeth were completely closed; she was unable to separate them, by any effort on her part; there was great pain below the left ear, and underneath the left side of the lower jaw which was greatly increased by any attempt to separate the teeth: she complained also of severe shooting pains on the left side of the face, and temporal region of the same side; the superficial glands under the jaw were enlarged and painful; her face was pale and bloodless, and presented the appearance of anxiety and bad health. I learnt from her the following history: twelve months ago, she had an attack of severe pain in the same situation, which was followed by almost perfect closing of the teeth; she had previously been in bad health; her business was that of a dressmaker, and she was confined much in-doors, at work: she applied to a medical man, who ordered fomentations to the face, and hot air baths; under which treatment she gradually improved, and she was able to open her teeth, but not to any great extent. She continued in rather delicate health until last January, when she had a recurrence of the attack; the teeth being very nearly closed, and the pain great. Her health became deranged; she suffered from languor and weakness; she was seen by a hospital surgeon, who ordered her tonics, viz., the cold bath, exercise, and steel. Her health improved, gradual relaxation of the jaw took place, and she was enabled to separate her teeth well; she continued in pretty good health up to the present time, July 3rd, when I saw her, labouring under the before-mentioned symptoms. Judging from the history of the case that the Trismus was owing to some local irritation, acting upon a nervous and weak constitution, I determined to use local treatment, combined with general antispasmodics and stimulants: I ordered six leeches to be applied below the ear, to be followed by fomentations, and a mixture composed of Dec. Aloes. Co., Tinct. Assafœtidæ, and Spirit of Ammonia, and a sedative of Opium and Camphor at bed time.

July 4th. Has passed a more comfortable night, from the opium; but she complains of great pain about the jaw, and the Trismus is quite as obstinate; she can take nothing but liquids; the pulse is rapid and feeble, countenance very anxious, bowels confined, there appears to be no spasm of the masseter muscle: ordered a blister below the ear, and the raw surface afterwards to be sprinkled over with gr. ij of muriate of Morphia; wine and arrowroot, to be taken occasionally. Mag. Sulph. ℥ j. to be added to the mixture.

July 5th. Has passed a very restless night; is in very great pain; she has only experienced temporary relief from the local applications; the pain attacks her in paroxysms, and her sufferings at those periods appear dreadful; she is considerably exhausted, and in an anxious state of mind; the teeth keep firmly closed together. She complains of soreness in the throat, and experiences difficulty in swallowing liquid; the pulse is rapid and feeble but there is no febrile disturbance. The bowels have been well opened. I determined to try the effect of cold water, poured from a height upon her face, but it did not appear to produce any effect. As she was much exhausted, and could take no solid nourishment, I ordered her to have wine and arrowroot frequently.

July 6th. On entering the room, to my great surprise, I found her sitting up with a cheerful countenance. She expressed herself much better, and I was at a loss to account for her sudden improvement, when she gave me the following account: Suddenly, in the night, she *felt something burst in* her mouth, and found herself almost choked by a quantity of matter, which she was unable to eject; this was followed by great relief to the pain, and relaxation of the jaw. She was enabled to eat some solid food. The teeth have separated, but not to any extent; she still complains of great languor, and she suffers pain under the jaw still, but it is not severe. The superficial glands are enlarged and tender. I ordered four leeches to be applied, and a dose of quinine to be taken twice daily, and what nourishment she was able.

July 8th. Is much better, she can open her teeth still more, she has only some occasional shooting pains on the left side of the face; empl. lyttæ below the ear; she eats solid food, and she is getting stronger.

July 12th. Is rapidly improving; she has been able to go out for a walk; her strength is returning; the teeth have separated more, and she does not complain of pain.

July 27th. I happened to see this young woman, when I found her health restored; her teeth have separated further, but not to the extent that they had before her last attack.

This case presents some interesting features. I believe it is a rare occurrence to meet with perfect Trismus alone, except in Hysteria. Contraction of the jaws occasionally results from inflammation of the joint, or from caries of the bone, but these cases are generally permanent. From the sudden termination of this case, from the symptoms of irritation about the jaw, and from the account she gave me, I think there can be no doubt that some abscess had formed about the jaw, and had suddenly burst. Although I suspected some mischief then, I must confess, that I considered, from the previous history, and from her having been cured in the last attack solely by means calculated to improve her general health, that it chiefly depended on constitutional causes, therefore I chiefly attended to the constitutional treatment, although I did not neglect the local treatment, by leeches and blistering, which probably had the effect of bringing about a more speedy resolution of the abscess.

The Queen of Spain has lately issued an important letter respecting quarantines. The quarantine of observation of four days, hitherto imposed on all vessels arriving from Maroc in a Spanish port, with a clean bill of health, will be omitted, for the future, in the case of Spanish ships, provided no case of plague shall have occurred in the port from which the vessel sets out, or its neighbourhood, during the space of one year. Foreign vessels will be required to present a certificate to this effect from the Spanish Consul of their sailing port, in addition to a clean bill of health, without which the old regulation will continue in force as regards them.

The King of Saxony has established a Royal Academy of Science at Leipsic, in commemoration of the two hundredth anniversary of the birth of Leibnitz, which took place at Leipsic on the 3rd of July, 1646.

A PRIZE ESSAY ON PURULENT ABSORPTION.

Communicated to the Medical Times

BY THOMAS OTTREY RAYNER, M.D., F.S.A.

(Continued from p. 384.)

I come now to consider one of the most important points of the subject; viz., the question, Upon what do the symptoms observed in purulent infection of the blood in the human subject depend? Are they due to any poisonous property of the pus itself? or to the secondary lesions it produces? or to other concomitant circumstances? I do not think I can better commence this part of the subject than by stating briefly the experiments and conclusions contained in a very remarkable paper by M. D'Arcet; an abstract of which is to be found in a late number of the *British and Foreign Medical Review.*

M. D'Arcet, reflecting upon the numerous and complicated symptoms which occur so often during the course of the disease, comes to the conclusion that they must be due to some cause additional to the constitutional disturbance necessarily attendant upon the formation of the abscesses themselves. In order to arrive at something definite, he performed the following experiments. Healthy pus being exposed to the action of the air, or of oxygen gas, purified and separated into two portions; the one an amorphous mass, formed by the coalition of the globules, and which floated at the top; the under part fluid, soluble, of a yellowish colour, fœtid, and containing sulphuretted compounds. Having washed the first portion he injected it, in what quarter is not stated, into the veins of a dog. The operation was generally followed by death in forty-eight hours, the animal having merely appeared dull, and suffered from dyspnœa, but no diarrhœa nor typhoid symptoms having supervened. On inspection, abscesses and phlyctenæ in the lungs and other parts were discovered. Injection of the subjacent soluble part caused severe typhoid symptoms, hiccough, vomiting, diarrhœa, rigors, fever, dyspnœa, depression, stupor, involuntary evacuations, hemorrhages from the mucous membranes, prostration, and death in five or six hours. The inspection revealed phlyctenæ in the lungs and other organs. He also injected healthy pus in 11 or 12 instances; but in two only disseminated abscesses formed. In the majority the typhoid symptoms occurred. In order to avoid fallacy, he used in some instances pus, procured by means of setons from the animals experimented upon, but without any difference in the results. From these experiments he deduces the conclusion, that pus in the blood produces two separate effects:

1. A disease of the respiratory, hepatic, or other organs, a local inflammation dependent on a mechanical cause, the capillary tissue being embarrassed by the insoluble or pulverulent principles developed in the pus, by its exposure to the oxygen of the air in the lungs; and not producing any other constitutional effects than those of inflammatory affections of the organs.

2. A miasmatic poisoning, caused by the absorption and circulation of some principles of the pus itself becoming putrid, acting on the blood in a specific manner, and producing grave and general symptoms, especially characterised as adynamic, and such as indicate a class of diseases where the entire organisation is intimately deranged, as the plague, typhus, purpura, glanders, &c.

Now, I agree with M. D'Arcet that many of the symptoms which precede death from purulent infection in the human subject, are often not to be entirely accounted for by the local lesions discovered; and I agree with him in looking upon infection of the blood by putrid or other unhealthy matters as affording an explanation of many of them. But I cannot agree with him as to their source; nor do I believe such symptoms to occur so generally as he appears to think; that is to say, I think that in many, even most, of the cases, the symptoms are sufficiently accounted for by either the preliminary or secondary local affections. The reasons for my dissent from his views are:

1. Because the serum and fluid constituents of pus, which soonest undergo decomposition, are readily excreted by the kidneys and other emunctories, and thus removed from the influence of the air.

2. Because the pus corpuscles, which resist putrefaction for a long period, are either arrested in different parts of the system before that change can take place; or being dissolved in the serum, are quickly excreted, as appears from the experiments, in which injections of small quantities of pus, were in a few days quite recovered from

3. Because the putrid symptoms in the cases in which they occur, are almost invariably to be explained by concomitant circumstances.

4. Because the results of my experiments differ very remarkably from those of M. D'Arcet, in one particular—the injections of healthy pus were never followed by the typhoid symptoms remarked in his cases; dulness, stupor, and dyspnœa were the only important ones observed; while in one which I made for the purpose of comparison, an injection of a very small quantity of putrid pus occasioned symptoms of a markedly different character, death following in about six hours. My experiments, however, being less numerous than his, do not afford results of equal value; a repetition of them may possibly lead to a change in my opinion. In the mean time I beg to call attention to the following tabular arrangement of 12 cases of phlebitis, and to the inferences to which they lead:

Author quoted, primary disease	Date of Seizure.	Possible Exciting Causes.	Symptoms in the order in which they occurred.	Date of Death	Lesions found at the original seat of injury.	Secondary or consecutive lesions.
Dance Arch. Gen. Obs. VI. Parturition.	10th or 12th day.	Drinking cold water while sweating.	Rigors, lassitude, dry tongue, diarrhœa 17th violent rigor, vague delirium, trembling tongue, P frequent R 40. Meteorism, incoherence.	18th day.	Uterus full of fœtid sanies, veins about the attachment of the placenta full of pus, also ovarian and hypogastric veins, softening of the uterine substance.	Inferior lobes of lungs full of abscesses, double pleurisy. Suppuration in symphisis pubis.
Dance Obs. VII. Parturition	9th day.	Too light clothing.	Irregular shivering, suppressed lochia, fever, diarrhœa, oppression, fœtid oozing from vulva, P. frequent, pain in abdomen, low delirium, subsultus.	24th day.	Uterine sinuses and ovarian and hypogastric veins filled with pus, softening of the tissue of the uterus.	Traces of peritonitis, pleurisy on the right side. Numerous abscesses in lungs. One in spleen. Pus in finger joint.
Dance Obs. VIII Parturition	9th day.	Exposure to cold.	Shivering, suppressed lochia, fever, diarrhœa, altered face, sanious oozing from vulva answers uncertain; no complaint; P frequent; dry T low delirium, dyspnœa	31st day.	Left uterine sinus and ovarian vein filled with pus. Blackness of Fallopian tube and ovary. Inflammation of peritoneum of the pelvis.	Double pleurisy, numerous small abscesses in the lower lobes of the lung. Softening of spleen and liver. Engorged cerebral vessels. Lymph effused under piamater.
Dance Obs. IX. Parturition	2nd day	None mentioned.	Shivering, diarrhœa, pain in head, and hypogast. for 20 days then general uneasiness; thirst, dry tongue, lochia scanty, P 120, then jaundice dyspnœa, involuntary stools no complaint	29th day.	Peritonitis, uterus full of yellow pus. Uterus spotted red. Two tumours external to uterus formed by the enlarged and purulent ovarian vein.	Slight injection of the piamater. False membrane the size of a crown piece on lower lobe of its lung. Two small abscesses in the same lung.
Dance Obs. III. Parturition	4th day	Labour long and laborious	Shivering, fever cephalalgia, hot dry skin, pale tongue, belly supple, lochia scanty, fetid P frequent, red conjunctiva, trembling	15th day	Softened and violet coloured neck of uterus. Uterine sinuses, large and purulent, losing themselves in the tissue of the organ. Softened Paterus.	All the organs natural
Hodgson Venesection for Ophthalmia	Not mentioned	None mentioned.	Gradually increasing fever. On 17th day, P. 20, skin hot, dyspnœa prostration; wound in vein open; pain in arm, symptoms increased, delirium.	7th week.	Cephalic vein thickened, obliterated from two inches above puncture to shoulder. Int. jugular enlarged, thickened, indurated. Ext jugular and sub-clavian purulent.	Small abscesses in the lungs, pleurisy; more serum than usual in the ventricles. Piamater tinged.
Rose compound fracture of leg.	12th day.	Erysipelas treated by incisions	Rigors, sickness, P 120, fever, dry T, hot throat, painful abdomen, stupor, insensibility, contracted pupils	20th day.	Erysipelas spreading all over the leg and abdomen. Incisions. No attempt at union of fracture	Piamater and brain more tinged than natural. Several abscesses in lungs. Two in liver. Two under capsule of spleen.
Rose. Fract. fibula Puncture in sole of foot	19th day	Erysipelas with diffuse cellular inflammation, incisions	Rigors returning for several days, and simulating ague, pulse quick, tongue dry, sweating, Ptosis, face yellowish.	26th day.	No account given of the state of the wound. Convalescent from the erysipelas	Opake arachnoid Lymph on under surface of ant lobes of cerebrum, and round junction of optic nerves. Suppuration into and round sterno-clavicular joints. Numerous small abscesses in lungs. One in liver
Dance. Obs XV. Amputation of mamma for cancer.	12th day	None mentioned.	Violent rigors, face sweating thirst; dry tongue prostration; answers slow, jaundice, pulse interrupted, pale at base of lungs; extreme feebleness, pulse insensible.	21st day	Pus in radial and ulnar veins, their walls thickened, pus in medulla of the bones. Several abscesses in the muscles. Many small veins inflamed.	Five or six small abscesses in each lung. Double pleurisy with effusion of lymph and serum. Red injection of cæcum
Arnold Venesection for pain of back.	Inflammation in puncture next day.	Perhaps epidemic.	Inflammation in wound pain in chest on a full respiration; pulse frequent, restlessness, thirst, swelling of arm, purging, rigors, weakness, irritability; pulse 120, prostration cough, delirium, dyspnœa.	30th day	Basilic and median-basilic veins impervious Small abscess in former above this it was lined with irregular false membrane.	Several vomicæ in lower lobes of lungs Some yellowish serum with lymph in pericardium Arachnoid opake, thickened, and milky. Several oz. of serum in ventricles. Abscess containing fœtid pus in substance of deltoid muscle
Arnold. venæsection 5 times for epilepsy.	Day after last bleeding.	None mentioned.	Pain and swelling in arm, skin yellowish; fever, dry tongue, great pain in arm; prostration; no pain in chest; dyspnœa.	7th day.	Whole length of cephalic vein full of pus; its coats hard, thick and red. Two inches of radial purulent.	Infiltration of pectoral muscle with greenish pus. 10 ounces of opake serum in the pleura. Both lungs full of hepatised portions, some purulent. Arachnoid opake, thickened and indurated.
Dance. Obs. XX. Ulceration opening the ductus choledochus, with mesenteric vein.	6th week.	Entrance of bile into the circulation.	At first, gastro-hepatic symptoms, then suddenly rigors, fever, swelling of the shoulder, forehead, and left temple, and diarrhœa, phlyctenæ and eschara about forehead, with oozing pus; teeth covered with sordes; prostration, low delirium.	21st day after seizure.	Ulceration of mucous membrane of gall bladder. Several ulcerations of choledochus opening the neighbouring large veins. Ulceration round embouchure of choledic duct.	Immense disorganisation about the head, with pus in the veins. Sinuses of dura mater gorged. Shoulder and elbow joints purulent. Lobular pneumonia, with abscesses in the lungs. Abscesses in the liver. Portal and mesenteric veins, purulent; splenic, and pancreatic veins purulent.

I have selected the above cases from the great number recorded, on account simply of the completeness of the reports furnished.

Now let us first consider them with reference to the symptoms of contamination of the blood by decomposed matter. Those enumerated by M. Bonnet, in his lectures on this subject, which will be found in the 21st vol. of the *Medical Gazette*, are "rigors, fever, acceleration of the pulse, loss of strength, very fœtid diarrhœa, pale yellow face." All these, with the exception of diarrhœa and yellow tint of the skin, are common to most extensive inflammations, and even the two excepted may be produced by a great variety of causes. Looking over the cases given in the foregoing table, we find, in three of the cases of uterine phlebitis, the coexistence of diarrhœa with a fœtid condition of the lochia or other contents of the uterus; in another diarrhœa, but the only mention made of the state of things within the uterus is that the lochia were scanty; in another the lochia were scanty, but there was no diarrhœa.

In two only of the other cases of phlebitis is the occurrence of diarrhœa noticed; in one of these there was a large abscess in the substance of the deltoid which contained fœtid pus; in the other, the primary lesion consisted in a cancerous communication between the mesenteric vein and the ductus choledochus, with ulceration of the mucous membrane of the intestine about the opening of this duct. Yellow tint of the skin is a symptom to which no importance can be attached in cases of phlebitis, on account of the local changes so often suffered by the liver. With regard to the other symptoms, I cannot find, after a careful study of the cases, any which the extent and situation of the lesions primary and secondary do not fully account for. I shall forbear, for the sake of brevity, to enter into any special illustration of this, but I believe that if the judges of this essay think it worth while to consider them attentively in this point of view, that they will coincide with me in opinion.

The inferences to be drawn from the above considerations are:—

1. That all the symptoms observed in cases of phlebitis with disseminated lesions are due either to the lesions themselves, or to some peculiar circumstance concomitant with each case.

2. That consequently no other effects are attributable to healthy pus circulating in the blood, than those caused by the embarrassment to the circulation, and to the local lesions to which it gives rise.

To render this essay at all complete, it will be necessary to enter briefly upon the consideration of a few of the complaints, the pathology of which, the facts that have occupied the foregoing part of it, tend to explain. The first and most important of these is cancer. Cancerous disease, under which name I include schirrus, medullary sarcoma, and colloid cancer, may develope itself in almost any organ of the body; but it commences by far most frequently in the female uterus and mamma. The tumour is at first circumscribed and confined to the organ in which it originates, but it increases with less or greater rapidity according as it partakes of the schirrus, or encephaloid character; it exhibits a tendency to involve indiscriminately, all the tissues in its neighbourhood. As the disease progresses, the tumour softens and inflames at various points of its substance, and at length bursting through the skin, forms a foul irregular ulcer with everted edges. At the same time with these latter changes in the primary growth, the glands in its neighbourhood become enlarged, and the same series of changes takes place in them. In the course of time, symptoms of affection of numerous other organs are developed, and the patient expires from the accumulated suffering and disease. After death cancerous growths are discovered in the lymphatic glands, the lungs, the liver, the bones, the muscles, the serous membranes and the skin; the spleen, the kidneys, and the eyes are also very common seats of secondary tumors.

The symptoms of these scattered growths commence sometime after the first tumour is developed, and generally date from its softening; they show, upon examination, evident marks of more recent production. When they are numerous, their development may be traced through all its stages, in the same subject.

It is a point of much importance to determine the actual tissue in which the secondary disease commences. Cruveilhier considers himself to have accomplished this with regard to the liver: and we may infer that it is the same in all other organs. In the most newly formed growths in the liver, it is easy to see that the disease is circumscribed to a few granulations, and the granular aspect of the liver is preserved. Cancer therefore commences in the substance of the granules. But their structure is very compound, and it is necessary to ascertain what anatomical element forms the

primary seat of the disease. Cruveilhier believes it to be the venous capillary system, for the following reasons.

1. "Because the veinules are very commonly seen filled with cancerous matter; and because it very often developes itself in great abundance in large veins, why not therefore in small veins also?

2. If we attentively examine a section of a cancerous tumour, and apply gentle pressure, cancerous matter oozes from the cut orifices of the vessels, in the form of small worms. That these vessels are veins, he was, in one specimen, enabled to demonstrate by carefully dissecting one of the larger ones into its minute ramifications, when he found the cancerous degeneration limited to the vena portæ.

3. An experiment by Prof. Berard, who found that an injection thrown into the arteries of a cancerous tumour coloured the whole mass, but he was unable to make it penetrate into the veins, these being blocked up by cancerous matter.

(To be continued.)

REVIEWS.

Outlines of Naval Surgery. By John Wilson, surgeon, R.N. 12 mo., p.p. 134. *Edinburgh*, 18[illegible].

This work professes to be nothing more than an epitome or outline of the subject it embraces, and in such light deserves commendation. Naval surgery, in all its bearings, has been so variously discussed by authorities competent to its correct teaching, that little of novelty remains to be said upon it. Nevertheless, as new facts and discoveries are not often to be looked for in matters appertaining to medico chirurgy; in the absence of such things, we are bound to feel obliged to those who bring summarily, and at a single view, before us, truths, which though not new, are of every day applicability and service. It is in this light that we are disposed to regard favourably the "Outlines" of Mr. Wilson. He writes like a practical man, and we therefore value his facts for their intrinsic importance, notwithstanding that they are now and then dressed in a garb, the reverse of epigrammatic or graceful. Here is a sentence for instance, in the dedication, which Cobbett's perspicacity and literary point would have prompted him to grumble at right well, had it fallen in his way.

"It seems unnecessary to state, at this moment, what may be the importance of the subject herein, however imperfectly treated, to, or its connection with, the best interests of the British as a maritime nation—health is strength—without it, it is easy to see, no ship, and no fleet can be efficient or capable of doing their duty."

We do most earnestly hope to see the day, when English literature will be more regarded by those who deal with it; and when authors, knowing how to cut and carve their sentences, may present them to us in such a form, that they will be intelligible at a single reading.

Mr. Wilson is a non-contagionist on the subject of "Febris intertropica violenta."

"Infection," say he, "succeeds, never precedes disease, therefore must be a property, or something acquired or engendered during or under disease, a secondary, therefore, not a first cause. From some source or cause this first case must have proceeded, but not from infection, to which it must have been prior, anterior, or pre-existent, and of which, therefore, it necessarily was and must have been independent. Is this fever subsequently or secondarily infectious? Can it be brought into existence by an endemic or epidemic cause, or some contingency, and then, by infection or some hitherto unknown process in the living system, radiated? In secondary as well as primary infection, there is much that is fallacious. For instance, had any party of men gone on board the Pyramus, to do duty in her enfeebled and sickly state, and a very probable proceeding, the most likely of all things would have been that most or all of them, according to their several susceptibilities for (of?) disease, and however inured or seasoned to the climate, or their own ship, would have been attacked with fever, and according to their several stamina, or powers of recovery, recovered, or their morbid predisposition, died, and what then would have been said? Just what was said in the case of the Eclair, and what has been said in a hundred others before, that the disease sprung from, and was continued by, infection, wh[illegible] in reality infection had nothing whatever to do [illegible] either with its origin or continuance. It would not have been imputed (supposing the cause not to have been found out) to deposition or decomposition—a want of cleanliness, a want of ventilation, or discipline, the cause of nine out of ten cases of fever or disease among seamen; but to a something no one could see, or no one could find." (p.p. 102—103.)

The following observations concerning frequent sources of impurity, or of infection, in ships, are very judicious and well-timed.

"The introduction of wood, green, rank and full of sap, into a ship's hold, in a tropical climate, and particularly during the rainy season, is a proceeding to be by all means reprobated, being, to say the least, perilous in the extreme, and much more so than is commonly imagined or thought of. To this may be attributed, and with reason, many of those cases of fever, so intractable and fatal, and in hot climates so frequent, and probably that of the Eclair. As still further illustrative, another sample may be given. In the year 1815, the Regalia, a merchant ship, went on a trading voyage to the coast of Africa. This case, it may be remarked, is related by Dr. Ferguson, army inspector of hospitals. When she sailed from England, the ship's crew were all healthy, and so continued all the voyage, and all the time they were there. Headachs, and other trivial cases of that nature, occurred from exposure to the sun or weather, but nothing further. Previous to leaving the coast, she wooded, and a large quantity of it, green and vegetating, cut in the woods on shore, was taken on board, and all stowed below, of course in an atmosphere, hot close and stagnant. The ship was bound to Barbadoes. Up to the time of her leaving the coast, and for about a week after, she still continued healthy, but from this, cases of fever, and both violent and intractable, began to appear, and spread rapidly on, about two weeks more from this time, on her arrival at Barbadoes; from the ravages and rapidity the disease had made, she was then found in a condition the most deplorable and alarming, several of the crew had died, several more dying, and all more or less ill. The cause and circumstances of the case became immediately the subject of investigation.

"On clearing the ship, and which was immediately, and very properly undertaken, it appeared that the wood in the bottom of the hold, which had been green and soft when taken on board, had become in this short space, that is, in about two or three weeks, through heat and confinement together, putrid and decomposed. From all parts of the ship's hold, effluvia, fetid, offensive and noxious, issued. The ship was cleared, cleaned, and ventilated, and the disease of course, disappeared. Wood, it is here particularly to be remarked, introduced into a ship's hold, whether for firing or other puposes, ought to be incapable of change, dry, hard, and particularly in a tropical climate. Soft, green, and vegetating, cut from the forests on shore, and stowed below, as it commonly is, is a proceeding most perilous, and one which, it is necessary to say, cannot be reprobated too strongly." (p.p. 114—116.)

We think this work very well calculated to be of service to the class of practitioners to whom it chiefly addresses itself.

Lectures on the Urine, and on the Pathology, Diagnosis, and Treatment of Urinary Diseases. By John Aldridge, M.D. 8 vo. p.p. 80. *Dublin*, 1846.

We are not told, by the author, in what place, or under what circumstances, these lectures were given. But for their denomination, we should be inclined to regard the whole as an essay, rather than a series of public discourses. Even the formality of heading each article, or lecture, as the case may be, by the usual starting-word, "Gentlemen," Dr. Aldridge dispenses with. Our author is a lecturer on chemistry, and in so far as the chemistry of his subject bears him out, he might have addressed a class at the Medical School, Park-street, Dublin, upon it, and then it would have been wise in him to say so; but additionally to the chemistry, we find a sprinkling of natural and morbid anatomy, with an occasional touch of treatment. As we do not learn from the title page that the author is physician to any public institution, we conclude that the discourse was not clinical; and as he publicly lectures on nothing but chemistry, we are at a loss, as we said before, to find the scene, or the occasion of these labours. We say thus much, because we feel assured Dr. Aldridge is a man of too much consequence to denominate himself other than what he really is. In the present day, there is a great rage for lecturing; every man gifted with a small amount of vocal or penfluency, feels himself in a position to lecture—that is, to TEACH. Many there be, who try thereat, and few there be, who accomplish it. We have even known a man ape the position of, and self-denominate his insignificant entity, lecturer on clinical medicine, because he ran to the beds of a few old men and women, *gratuitous patients*, in certain alleys and corners of a large town, followed by one or two school boys, who knew no better than to listen to his nonsense. Idle absurdity like this, we shall ever condemn, when we find occasion for it. In all practical points, Dr. Aldridge's pamphlet does him much credit. It makes no pretentions to scientific depth, or to originality; but it is an excellent *resumé* of all previously written on the pathology of urine. The style is simple, unpretending, and exact—the facts comprehensive, and what is much more, *comprehensible*—and the applications clear and judicious. To the practioner uninformed on this subject, and especially to the student, we have much pleasure in recommending this monograph, as one of the best elementary treatises extant, on the pathology, diagnosis, and treatment, of urinary diseases.

TO CORRESPONDENTS.

Humilitas *should either become a subscriber to the General Medical Annuity Fund, or insure his life.*

A Subscriber *will find full information respecting the requirements of the College of Physicians, in either our last Student's number, or our Almanac for* 1846. *A printed copy of the questions at the last examination will be forwarded on application to the registrar, and from it* a Subscriber *will be able to form a better general idea of the nature of the examination than we can give in the limited space of our correspondents' column. Pinel's work on the nature and treatment of insanity, is decidedly the most valuable in any language, and* a Subscriber *may well imagine that it has lost nothing by its being transferred, in an English dress, to our pages, under the care of Dr. Costello, the learned Editor of the Encyclopædia of Practical Surgery, himself the proprietor and superintendent of a large and ably conducted lunatic asylum.*

Un Allemand, *if ill, should consult a medical man, if not ill, he had better not take medicine. We never prescribe in the* Medical Times.

Alpha.—*We think not.* Alpha *himself answers his second question.*

A Constant Reader *should have sent us his name. Anonymous personal attacks should always be avoided. A member of the College of Surgeons, and M.D. of a Scotch university, cannot certainly be considered an unqualified practitioner. Such distinctions are obsolete, they belonged to a less enlightened, and less generous age.*

Mr. J. J. E. Foster's *attack is too personal for our pages.*

An Irish Subscriber.—*Only twelve meetings are held of the Surgical Society of Ireland. They all take place during the winter Medical Session. The Pathological Society of Dublin meets weekly during the same period. Valuable papers are read at both societies. We do not know the terms of membership. Full reports of the proceedings of these societies are published in the* Medical Times.

A correspondent warns us against a practice advertised to be sold at Birmingham. He affirms it to be a quack affair of a disgraceful kind.

Miles *writes us a long letter on the Flogging inquest. He asks what Mr. R. Wilson means by connecting as neighbours the sixth and seventh pieces of the spine with the sixth and seventh ribs, in his report; insists that the pretty piece of nonsense about* ruptured *muscle, and pulpy softening, is proved to be moonshine by the fact recorded by Dr. Warren, that there were no convulsions, and by the fact that the muscles on post mortem examination, were found healthy by four other medical men. He goes on to enlarge on the coarse jokes and fits of laughter enacted or provoked by the dignified coroner, on the self-puffing à-la-Goss of Wilson, and other remarks which we have anticipated elsewhere.*

A Fellow *sends us the report of* " *The Fellows Dinner*" *given at the Free-Masons' Tavern immediately after the election of the Councillors. Mr. Travers, was in the chair. The only incident of importance was a forcible declaration by Lawrence that the Council would resolutely persevere in their unpopular courses if supported by the Fellows. The declaration was received with enthusiasm. There were about 150 Fellows present. Mr Green was one of the speakers.*

M.C. *We do not give prescriptions.*

THE MEDICAL TIMES.

SATURDAY, AUGUST 1, 1846.

" See how yon justice rails upon yon simple thief. Hark, in thine ear: change places; and handy dandy, which is the justice, which is the thief? *** Get thee glass eyes; and, like a scurvy politician, seem to see the things thou dost not."—LEAR.

NEVER were we more convinced that, in the indignation at a large abuse, all sense of its minor contingencies is often prejudiced and marvellously misled, than while ruminating on the circumstances of the late inquest on White, the alleged victim of flogging barbarities. As a whole, such a gross, perverse, and hideous caricature on English administrative justice, in the name of justice, we never witnessed. Beyond the unavoidable good of subjecting to public animadversion the Vandalism of *all* military flogging, there is not a feature presented to us *judicially* in that investigation, that commands respect, or deserves aught but censure or contumely. There was something absolutely execrable in the Coroner's farcical impersonation of judgeship. Legal axioms, and the spirit of English jurisprudence, make the judge the counsel of the accused: here the Coroner had no thought, word or act save for inculpation. Coroner Wakley *seemed* like a man compromised to infamy, or worse—personal unhappiness—if it should be proved that White died without murderous guilt in some survivor. This medical magistrate would evidently not conceive the hypothesis that some brother medical practitioner had not betrayed the trust of humanity, and proved himself an assassin. The anxiety of the merciful president of this dignified court appeared to be to clothe every act with criminality, and strip every circumstance of innocence. He *coaxes* private soldiers into conjectural charges, and tries to bully medical witnesses out of honest convictions—all to throw blood at the door of a worthy medical brother. He suggests, insinuates, applauds, encourages, assails—twists, twirls, and manœuvres—in every shape, form, and direction, to conjure up against an honest practitioner a fictitious semblance of murder! Why all this? Why this reckless sacrifice of good men's repute and peace of mind? Why this needless display of ingenuity to get up against Dr. Warren, or failing him, Colonel White, or failing him, the farrier, a colourable semblance of murder? There is of course but one reply—*Wakley wants a public sensation to help his fortunes in a forthcoming election.* There is something to excite the gravest reflection in th frightful prostitution of an English magistrac to the purposes of a popularity seeking poli tician. There is no knowing where it may en or to what perils it may carry us. The ver needs of a fiercely competing press, deprived great political events for discussion, yet requir ing for successful sustenance the aid of stron popular sensations—the very needs of such press suggest fearful dangers from this unscru pulous use, by judges, of the machinery of la to the purposes of political emergencies. No only is the whole idea of administrative justic brought into disrepute by the incongruou melodrama, but an illicit means of popula power is evoked, which, supported by anythin like character and sustained ability, would lea to very great public mischief.

Flogging is an *institution* of the army, rude an brutal, that cannot too soon be done away with If our soldiers be of so low a nature that they ar ungovernable without it, the causes of th anomalous degradation should be removed, tha our country may be relieved at once of a hor rible evil, and, if possible, a still more horribl corrective. But flogging being an existing legality to be administered by the officers o the army, with no more chance of escap than a judge of the land possesses when called on to execute the worst law on the statute book, it behoves us as a first duty in a inquiry like this over White, not withou the strongest possible grounds of inculpation to throw the inevitable evils of a bad system on those whose duties make them its administrators. Now, what are the facts of this case which distinguish it from any others occurring under the operation of military law?

First.—The sentence —150 lashes, though severe, is below the average punishment customarily awarded by military law for the offence —an assault on an unarmed superior officer with a murderous weapon, a poker. If the law be bad, correct it: while it is as at present, military judges can do nothing but enforce it.

Secondly.—The administration of the punishment was attended by no peculiar circumstances of severity. White enjoyed, it is fair to presume the customary robust health of a young English soldier on constant duty. Dr. Warren, after a minute examination, certified, under officia sponsibility, to the fact. The flogging was rfectly of the usual character: the evidence though somewhat discrepant, leaning to the supposition that it was rather lighter than severe; and Dr. Warren's non-interference favouring the hypothesis. The flogging took place on the 15th of June; the usual course to convalescence went on till July the 4th, when he was officially declared well and fit for duty; but instead of being discharged on the 6th, to his duty, as it was intended, White betrayed on that day *commencing* symptoms of some internal disease. For the first time he complained of pains in the region of the heart. After five days' illness, he died on the 11th of July, evidently of an acute disease—27 days after the flogging. Dr. John Hale, a staff-surgeon, sent down to Hounslow to see the patient on the day of his death, thus describes the progress of the disease, in a letter written on the same day to Sir James McGregor:—" White, it appears, received a corporal punishment of 150 lashes on the 15th of June, for military insubordination, which was inflicted in the usual manner in the presence of Warren, and without any degree of sev calculated to attract more than any degree of ordinary attention. His back healed kindly, and nothing occurred to mark his case until the morning of the 6th instant, the day on which he was to have been discharged from the hospital to his duty, when he began to complain of pain in the region of the heart, extending through to the back and shoulder blade, which increased in severity, notwithstanding the measures adopted by Dr. Warren for its relief, until yesterday morning, when paralysis of the lower extremities and retention of urine were discovered, and he died, as I have stated above, at a quarter past 8 o'clock this morning."

A *post-mortem* examination took place within 24 hours of the death, of which the following is the statement:—

" *Post Mortem* examination of private Frederick White, of the 7th Hussars, aged 27, made 42 hours after death, in presence of staff-surgeon Dr. Hale, surgeon Dr. Warren, 7th Hussars, and assistant staff-surgeon Dr. Reid;

" General appearance—Body muscular, and not much wasted; marks of venesection at the bend of the right arm; marks of a blister on the epigastrium, and of another on the back below the scapulæ; marks of corporal punishment across the shoulders, particularly over the right scapula, but the punishment does not appear to have been severe, and the part where it was inflicted was quite healed; back discoloured from the gravitation of blood since his decease. Thorax —right side—Old adhesions binding the lung to the ribs and diaphragm throughout its whole extent: left side—inflammation of the pleura with recent adhesions, and effusion of serum, containing shreds of lymph to the extent of 12 oz.; lung engorged and infiltrated with serum. Heart—Muscular tissue soft and friable throughout; endocarditis on both sides of the heart, the inflammation extending some distance along the pulmonary artery, and over the valves of the aorta; cordæ tendineæ of the tricuspid valve matted together with fibrine; pericardium healthy, and not containing more than its natural quantity of fluid. Abdomen—Liver enlarged, and extending three inches below the margin of the ribs, but not altered in colour or structure though there are old traces of inflammation on the peritoneal covering of the right lobe; gall bladder small, and containing a portion of pale-coloured bile; kidneys, bladder, and spleen healthy; intestines distended with gas, but healthy. Head —dura mater healthy; pia mater injected, and the tunica arachnoides opaque in several places, similar to what is generally found in confirmed drunkards; lateral ventricles capacious but empty; plexus choroides enlarged, and the veins running along the floors of the ventricles distended; substance of the brain marked with bloody points when cut into, and softened at one point on its under surface. A portion of integument was dissected from off the shoulders and spine, where he had been punished, and all the parts underneath were found perfectly sound and natural. The integument itself, with the exception of some discolouration of the cutis vera was quite healthy.

" JOHN HALE, M.D., Staff Surgeon, First Class.

'July 13."

'Copy of a Certificate which was drawn up and signed by the party present at the *post mortem* examination, for the satisfaction of the officer commanding the 7th Hussars.

" Cavalry Barracks, Hounslow, July 13.

" Having made a careful *post mortem* examination of private Frederick White, of the 7th Hussars, we are of opinion that he died from inflammation of the pleura and of the lining membrane of the heart; and we are further of opinion that the cause of death was in nowise connected with the corporal punishment he received on the 15th June last.

" JOHN HALE, M. D., Staff Surgeon, First Class.

" J. L. WARREN, Surgeon, 7th Hussars.

" F. REID, M.D., Assistant Staff Sur."

The further evidence given by these three gentlemen as to the cause of death supports the report.

Dr. Hale tells us:—" He was treated for inflammation of the pleura of the heart. There were found, on examination, old and strong

adhesions on the right side of the heart, and inflammation and recent adhesions on the left side. The pleura pulmonalis and pleura costalis were inflamed; the lungs were not inflamed. The pulmonary artery and the aorta were inflamed for an inch and a half; the pulmonary vein was very slightly inflamed. The inflammation extended from the heart to the larger vessels. There was no inflammation of the pericardium. The cause of death was inflammation of the heart and pleura, but it was impossible to say what was the cause of that inflammation. I have seen the history of the case given in the register, and I should ascribe the inflammation, to the change of temperature at the time the deceased was recovering. A change of weather, bringing rain and cold winds after great heat, took place in the end of June. A corporal in the regiment I know died yesterday from inflammation of the lungs. I do not think that the death of White had any connexion with the punishment he received."

Dr. Reid says:—"I have heard Dr. Hale's evidence, and agree in it. I look on the endocarditis as the immediate cause of death. The lining membrane of the heart was of a deep red, and this was not from the imbibition of blood, for it was not present; nor was it from decomposition, for the heart was not decomposed. The membrane was thickened by effused fibrine, and soft and slightly adherent. The membrane itself was readily torn from the heart, showing the decreased vital cohesion, and there were polypiform concretions of uncoloured fibrine adherent to and interlacing the fleshy columns and the cordæ tendineæ. That proves the inflammation to have been recent. In the left lung there was pneumonia in the first stage, but I do not attach much importance to that. The marks of pleurisy on the right side, and of inflammation in the liver, were of old standing."

Mr. H. G. Day, M.R.C.S. and L.A.S., says:—"I live in Church-street, Isleworth. During his life I did not see the deceased man, but on the Thursday after the death. I examined the body in the presence of my partner, at the barracks. I knew nothing of the history of the case previously. I opened the cavity of the chest and abdomen, and found the parts very much decomposed, and, of course, out of their usual position. The heart appeared rather smaller than usual, and of a softened texture. It had been cut open in each direction. I saw nothing decided about the lining of the heart, though it appeared rather inflamed and redder than usual. The lungs appeared gorged, particularly the left side. There were traces of inflammation on the left pleura, but I cannot speak of adhesions, as they had been torn through. The portion covering the ribs was more inflamed than that covering the lungs. The body was in a very decomposed state, and it was difficult to make observations. The liver looked larger than usual, and I thought rather paler. I have heard all the evidence thus far, and I think the cause of death was pleurisy and pneumonia. I suppose the death was caused by change of temperature and exposure to cold."

One might fancy that with all this evidence of four medical men, all in strict coherence and mutual support, and with all this natural sequence of morbid phenomena which are occurring in every-day practice—that there was really very little of the mysterious, or the marvellous, of the extraordinary in this poor man's death. Every circumstance, indeed, seems to have concurred to strip the business of what, in theatrical language, may be described a startling situation or dazzling effect. But the sagacious, popularity-seeking coroner was not to be disappointed. He had opened the public's mouth with wonder and curiosity, and it would be hard indeed if, with his unscrupulous ingenuity, he could not get something wherewith to fill or amuse it. Accordingly his *protege*, Mr. E. Wilson, formerly sub-editor of the *Lancet*, "Wakley's ambulatory *post-mortem* man," as he is generally called, was despatched to exhume the body a fortnight after the death—the three surgeons whose characters were implicated in the examination being carefully excluded by a special order of the prudent coroner (*that* coroner who makes such public scenes to have the accused *present* at inquests to hear the evidence alleged against them). A body in the last stage of decomposition, after a fortnight's interment, during the heat of one of the hottest of summers, is an excellent subject for finding in it whatever may be wanted; and the coroner's scientific hanger-on and partner in *post-mortem* fees is not long in finding out a pathological "discovery which had never been made before"—we quote his own words—"a discovery not to be found in any volume yet published." The microscope, that disenchanting instrument, which, in the hands of the youthful, ardent, unscrupulous, fame-seeking discoverer, has penetrated already the innermost recesses of organic nature, shown us the primordial cell of this nether world, verified by intuitive evidence, the wildest theories of the Greek philosophers, and through which the imaginative anatomist may, with every facility, see whatever he likes, tinting his glasses with phantasmagoric effect,—this wonderful instrument of talismanic qualities, enabled the writer of *Healthy Skin*, "a book, he is happy to say, that is out of print," to detect in the deepest muscles of a putrid corpse injuries they never could have sustained—muscles unapproachable even by convulsive action—and to "discover" that they occupy a position in regard to the membranes of the chest which they have never been known to hold since the creation! We appeal to the common sense of any medical man, if credence can be placed in the testimony of any writer—whether he be a book compiler or not—who tells a public court that the multifidus spinæ lies on the membranes of the chest; that an inflammatory action, arising from a disorganized muscle, can traverse a plate of bone of at least half an inch in thickness, and that a muscle whose actions at all times must be of the feeblest character, (and which in the grown man is of a half-tendinous structure, and therefore not susceptible of the smallest action under any circumstances,) can be suddenly seized with convulsions which spare the enormous and energetic super-imposed masses of muscle from the longissimus dorsi to the integument: masses of muscle, so susceptible of convulsive action themselves that, from a slight injury to the foot or head, they bend the body back into an arch, presenting the frightful appearance of opisthotonos. We are almost ashamed to dilate on the ignorance and bad intention of this enormous blunder, including under it a succession of blunders, any one of which would be damning to the youngest country apothecary. The *Healthy-Skin* gentleman, to suit the wants of his friend the coroner, swears that layers of muscles of enormous power, and quick sensibility from their contiguity to the integument, remain passive, though all but touched with the instrument of punishment, while a muscle almost devoid of muscular action, and seldom, if ever, used in the adult (to show which an anatomist resorts to a subject not more than 15 years of age, so early does it lose its muscular character) is endowed by him, in the teeth of all science and experience, with the opposite qualities to those which it possesses and ignorantly displaced from its natural position to be brought in contact with a membrane which it cannot touch, and all this to give a colour to a charge of legal assassination against a body of gentlemen—one of them a medical brother—for simply performing, and with extreme reluctance, those duties for which they are held responsible by their country. We believe that such a "discovery," and for such a purpose, never before formed the distinction of an English anatomist, and, we hope devoutly, never will.

We give this worthy person's evidence from the *Times*. A more unblushing piece of professional quackery, got up between himself and the coroner, including the address of the practitioner, we never read; and we will only further observe in reference to it, for the sake of our unprofessional readers that Mr. Wilson's "discovery" is not mended by the ingenious device of extending the alleged pulpy degeneration of the muscle to the adjoining part of the external intercostals—muscles to which he has vaguely alluded, prudently, however, withholding their name for reasons known to every anatomist and physiologist.

"Mr. Erasmus Wilson, the next witness called, said—I reside at 55, Charlotte-street, Fitzroy-square, and my profession is that of a surgeon. I am a Fellow of the Royal College of Surgeons, Edinburgh; Consulting Surgeon to the Royal College of Surgeons of London, and Lecturer on Anatomy and Physiology. Some years ago I was Demonstrator in the University College. I have written a work on diseases of the skin, and another work entitled *Healthy Skin*, which I am happy to say is out of print. Mr. Wilson then read the following statement of the observations made by him on examining the body of the deceased, and the conclusions which he drew from those obervations:—

"On Wednesday, July 22, I made a *post mortem* examination of the deceased, my attention being especially directed to his back and spine. On the skin over each shoulder there were marks of lashes, and on the right of the middle line between the shoulders there was a large gap occasioned by the removal of a portion of the skin. A small bottle containing a piece of skin was handed to me by the serjeant of police. I took the skin from the bottle, and found that, though much shrunk by immersion in spirits of wine, while the gap from which it had been removed was stretched to its utmost, yet that it corresponded with the gap, with the exception of the side nearest the middle line, where a part had been cut away and lost. I was informed that the last piece had been cut away in order to make the remainder sufficiently small to enter the bottle. From the position which the last piece occupied, I believe it was more protected from the lashes than the preserved portion, and, therefore, being less interesting, in a medical point of view, had been cut off. On the preserved portion of the skin there had been several marks made by lashes; the marks were red, and upon cutting into one of them, I found that the redness, which was indicative of inflammation, extended through the entire substance of the skin. On raising the muscles, or flesh from off the ribs and spine, I find a part of the deepest line of muscles, viz., that which lies in contact with the bones, in a state of disorganization, and converted into a soft pulp; in medical language, I should call this a pulpy softening of the muscles. The seat of this pulpy softening was the sixth and seventh ribs, near their attachment to the spine, together with their intervening space and, the hollow between the sixth and seventh pieces of the spine. The extent of the disorganization was about three inches in length, by about one inch and a half in greatest breadth, and between a quarter and half an inch in thickness. In the space between the ribs the muscles

had undergone this pulpy alteration, even so deep as the lining membrane of the chest, the softened muscles being in absolute contact with the lining membrane; that portion of the flesh which occupied the groove of the spine, and had undergone a similar disorganization, was one of the little muscles known to medical men under the name of the multifidus spinæ. In addition to softening of this little muscle, it was partly surrounded with blood. It was in a state medically called ecchymosed; the interior of the spine was in a state of extreme decomposition; the tissue between the spinal canal and spinal sheaths was filled with a dark coloured fluid, resulting from decomposition; the sheath itself was smooth and polished on its internal surface—a state indicative of health; it was perfectly devoid of nervous substance, which had been converted into fluid by decomposition, and had flowed away. The nerves remained, and presented a healthy appearance, so that, so far as the spine is concerned, I discovered no indication of disease. Two questions naturally arise out of the preceding examination—first, what was the cause of the pulpy softening of the muscles? secondly, could the state of disorganization, preceding the pulpy softening, influence the disease existing in the chest? The cause of the pulpy softening I believe to have been the excessive contraction of the muscles taking place during the agony of punishment. This excessive contraction would produce laceration, subsequent inflammation of the muscles, and the inflammation instead of being reparative would, in consequence of the depressed state of the powers of the nervous system of the sufferer, be of the disorganizing kind which results in pulpy softening. Had the man lived the disorganization of the muscles would, in time, have been repaired: as regards the second question, there can be no doubt that, although the common cause of inflammation of the contents of the chest is cold, acting in conjunction with physical or moral depression, and might have been the cause in the case of the deceased, yet the presence of a portion of muscle in a state of disorganization and inflammation, in close contact with the lining membrane of the chest, might be adequate to the production of the same effect. Certainly no surgeon would feel comfortable with regard to the state of his patient if he were aware of such dangerous proximity."

> Maxima pars vatum, pater et juvenes patre digni,
> Decipimur specie recti.—HORACE.

IN pursuing the subject we were discussing last week, let us, having finished with the collegiate life of clerical and medical students, look at them in their future professional career. We have already proved that, as a rule, the education of medicine is superior to that of the pulpit; and that the intellectual position of the physician or surgeon is at any time equivalent to, and often much above, that of the clergyman. We know that exceptions are occasionally met with, but these only prove a rule which we state thus broadly.

Now as to the status of each, as respectable citizens and approved moral characters, we utterly deny that the clergy have the smallest advantage over us. We do not mean to visit upon the mass of them the sins of a few, and say, because sundry of them are sinners, they are all of them summarily more or less so. Because, here and there, one of the "good old school" will hiccup a chorus to the tune of "A jolly full bottle," that he is any proof of his brethren being, *toto cœlo*, bacchanalians—because another glories in covering a scarlet coat with a surplice, that they are Nimrods every man—because a third nurses his housemaid on his knee, and proclaims to the less favoured lookers-on that—

> "It's all reality,
> No formality,"

he is any evidence that others of his cloth are more devoted to Venus than virtue. These, again, are exceptions, and the pulpit is not singular in being disgraced with them. It is the rule we are contending for, and we unhesitatingly aver that there is no greater personal respectability, and no purer morality, amongst the members of the clerical, than amongst those of the medical profession. We not only aver thus much, but we unhesitatingly challenge the world to prove the contrary. The clergy in general we know to be forward in any object having the welfare of their fellow-creatures at heart—many of them give largely of what they possess, and cheerfully devote their time, talents, and substance to the cause of humanity. It must be understood, however, that they have nothing else to do; and that these several items of charity are so many features of character which they pledge themselves to, and which most of them are well paid for representing. Nothing of this kind is absolutely required of the medical man—his profession could be scientifically and skilfully practised without such moral ornaments—and yet, how beautifully, how bountifully, they shine in him. He is not committed by oath or by promise, to benevolent or to philanthropic purposes, apart from his calling, and yet he is fulfilling these larger duties every day of his life. Rarely is any public scheme propounded for the "safety, honour, and welfare" of his fellow-creatures, but the medical man is a grand accessory to its origin and progress. Charity hardly records an enterprise unconnected with his name. From pausing, like another Samaritan, to heal the wounds, and help the weariness, of the afflicted, in the humbler and more deserted pathways of human life, where no eye, save that of God, regards, and none other recompense rewards him; up to that more liberal and open beneficence which the world views with ostentation, and requites with empty praise—from the one extreme to the other, the medical practitioner is perpetually employing himself in the service of his fellow-beings. We may be charged with bestowing panegyric upon a society of which ourselves are one; but we are speaking the truth nevertheless, and shall not fear to utter it, though it be imputed to us for vanity.

Now, why, let us ask, should one of our own community be less regarded, respected, and recompensed than his fellow in the church? What has the latter done, or suffered, that the former has not equally, or more largely, shared in? What public or private good does the one do, that is not also done by the other? None! emphatically, none! But we *can* say, that the physician and surgeon often perform services, without fee or reward, which the clergyman will not parallel unless he be paid for it. Look at these two facts. We are intimately acquainted with the condition and management of a large workhouse, containing some three or four hundred beds. Six surgeons attend to the patients in this place, and, additionally, have to attend, at their several homes, the paupers comprised in a town population of more than two hundred thousands. Six men have all this labour, which is sometimes so distressing, that, as one of them said to us the other day, "galley-slavery would be preferable to it." For this fearful toil, both bodily and mental, each man is remunerated with *twenty pounds a year!* To say nothing of his food, the sum will actually do no more than compensate for the wear and tear of clothes in the service. The six men, well educated, well skilled, and worthy of better pay, get among them, *one hundred and twenty pounds a year!* The chaplain to the workhouse, for Sunday duty, and an occasional visit of religious condolence, is paid annually *one hundred and fifty pounds!* For doing about a tithe of what each of the surgeons does singly, he gets, at the end of every twelve months, thirty pounds more than all of them put together! Now, in all common propriety, is this fairness? Is it anything like honesty? We quote this case, not because of its singularity, but because it is one which is personally known to us, and for whose accuracy we can vouch. There is nothing novel in it, we feel assured; plenty of examples, equally notorious, might doubtless be cited. We are not complaining that in these cases, the chaplain gets too much, but that the surgeons get too little. "The labourer is worthy of his hire," no doubt of it, and we are far from grudging the parson his pay—but why, we ask, are not the other labourers, who are equally deserving, recompensed as well? We affirm this paltry partiality to be a gross sin against that common honesty and justice, without which humanity does not even deserve its name.

Take the other case. We know an hospital, the medical officers of which not only attend all the in-patients and out-patients gratuitously, but annually pay over to the funds of the establishment, from three hundred to five hundred pounds, derived from students' fees to clinical lectures. Whilst the medical officers do thus much gratuitously, the chaplain does not even administer a cup of cold water in the name of his Divine Master, *without being paid for it!* Whilst six medical men serve this cause of charity "without fee or reward," not a man can be found amongst those whose sole business it is, or ought to be, to "go about doing good," to preach even the Gospel of God without a *bona fide* sum in hard cash as his compensation.

This case, again, is not singular; we know of many such. We are not acquainted with an hospital, the kingdom through, in which the non-resident medical officers are paid for their services to the sick; nor do we know of one in which the chaplain does his duty for nothing!

Be it understood, once again, that we are not complaining that the clergy make *their* demand, where we hesitate or refuse to make *ours*. Perhaps they are the wiser for doing

so; for they escape two notable vexations—imposition on the one hand, and penury on the other! But, in the contrast, let us ask which character shines the fairer? Which is the greater benefactor of the two? And which, of the public, deserves the better praise? Certainly not the man who gets it. When a new curate comes to a town, whether his pretensions be lofty or lowly, he becomes the fashion, and the favoured of the people: they greet his entrance with a triumph, and his exit with a tribute. Before he has stirred a step in their service, they take his goodness for granted, and give him the welcome of an old friend; when he leaves for "a better berth," they think him a martyr, and pay him accordingly. However excellently, or indifferently, he may have done his duty (for doing which, be it remembered, he has received his fees, aye, and his *feed* too, pretty regularly), there are always plenty of sympathies ready to suggest the getting up a trifle, if it be only as a *memento!* Dear kind man, he has preached to them, and has been paid for it; he has prayed for them, and called in at dinner or dessert time as often as he chose! This is how the parson is appreciated, applauded, and provided for! Is any such benignity bestowed on the medical practitioner? For having done gratuitously what the parson is well paid for, himself never gets more than a frigid vote of thanks. How many services of plate, and purses of gold, have been given to the clergy for having done nothing more than they bargained for; whilst the members of the medical profession have been allowed to leave hospitals and dispensaries, after years of gratuitous service, with a cold compliment for their reward! Again we say, is there not injustice in these things? Ought not the public to be ashamed of its partialities?

Here we anticipate an old crotchet, in answering which we close this part of our subject. It has been said that medical men are recompensed for their services, gratuitously given, by the introduction which is thus afforded them to practice; and that the clergyman ought to be paid in hard cash, because he has not the benefit of such introduction. In answer to the first part of this, all we can say, from pretty extensive experience, is, that for our public duties we would have preferred one hundred and fifty pounds a-year, regularly paid in mint money, to all the extra fees that the pauper attendance could introduce us to; and we apprehend that most institution-practitioners would say the same. As regards the second clause, we find the parson, as usual, stealing a march upon us. He is not only *paid* for his public position, but that very position gives him a publicity: and what is this, if creditable, but another name for *preferment?* Why does a man take a curacy of fifty pounds a year, but that he hopes he may soon get one of a hundred? Why one of a hundred, but that he hopes it will one day double itself? Curate, vicar, rector, prebend, bishop—all are the perquisites of the pulpit and good luck! Not only may a man in the lowest station aspire to the highest in the Church; but, contrary to ourselves, he has not to wait with empty pockets, between one extreme and the other, but is well paid in his several gradations. Thus, then, we see the double inducement of the clergyman—he is not only requited for his present position, but enjoys, additionally, its prospective advantages. Ourselves have neither. We have no recompense secured for protracted public service in hospitals, dispensaries, &c., and no "living well tithed," no honourable denomination, after lengthened servitude.

Why should the clergy have these privileges over us—their equals at any time, their superiors often? Why have we no endowments, as the honourable rewards of servitude administered for nothing? Why should title, emolument, and a seat in the highest legislature in the kingdom, be the recompense of the deserving, or the fortunate in the clerical profession; whilst to the medical, every chance of such preferment is denied? We are not less, intellectually, morally, or beneficently, than they, and wherefore do we fare worse? Have we not, with them, equal hearts to feel for and succour our fellow-creatures, and equal heads to govern them? We put these questions to the legislature, but most of all to the public, and "we pause for a reply." If we have it not, nothing daunted, we will continue to AGITATE until justice be done us!

Miscellaneous Correspondence.

THE PROVINCIAL ASSOCIATION AND THE GENERAL PRACTITIONER.

To the Editor of the Medical Times.

SIR,—I shall be obliged to you if you can find a little space in your columns for the insertion of a running commentary upon the lucubrations of a certain Dr. David Bell, published in the hebdomadal organ of the Provincial Medical and Surgical Association. The worthy gentleman sets out, by expressing a wish that "the Provincial Association" should maintain its position, in order to impress upon the government of the day the urgent necessity of re-arranging the laws by which the profession is governed. Does this elegant stylist know that those "much-to-be-desired changes," which the Provincial Association advocated three years ago, tended to the destruction of the class of the general practitioners, and to the elevation of the dubs and pures, who are the managers, despots and puppet-players of the Provincial Association? The influence of this association was employed to the political degradation of its members; and if Dr. David Bell wish to keep it alive for such a purpose, I trust that the general practitioners will resent the jesuitical and selfish scheme of their rulers, and forthwith withdraw from the Society.

He quaintly informs us that there is a large class of malcontents—by far the most sensible portion of the Association, who ask, "what amount of good has it effected?" and a little further on, he adds, in the guileless simplicity of his heart, that whenever he endeavours to promote the interests of the Association by conversation with general practitioners he is "told by them that they fear *we* gain no ground." The egotistical *we*, printed in italics too, refers to Dr. David Bell being a *member of the Council* of the Association! He admits also that they express dissatisfaction with the condition of the Journal as compared with others (why not have named the *Medical Times* at once?) and he acknowledges with that magnanimous frankness which must be so cordial to the feeling of Drs. Hastings and Streeten that the complainants have "truth on their sides." "Et tu Brute!"—mine own familiar friend!—the apologist of my frailties to expose them also mercilessly,—yourself a contributor, to sneer at the very pages you have assisted to blot! This is indeed too bad. Dr. Streeten might regard with complacency "the rent the envious Casca made," or even forbear to weep over the place where "ran Cassius' dagger through," but the hideous spot where the much-beloved Brutus stabbed, is "past all surgery."

In sober seriousness, Sir, the Journal in question is acknowledged even by its avowed defenders to be a thorough disgrace to medical literature. It ought not to be allowed to exist: and if the members at their next annual meeting, do not come to a vote to terminate its publication, they will not have done their duty either to themselves or to the literary character of the profession. It is a literary mendicant asking alms for its support, when it ought to labour hard for its own maintenance—or die. Die it must, in a very short time: it was born an abortion, vegetated as a dwarf, has been for a considerable period sinking under a marasmus, and not all the galvanism of Dr. David Bell, however skilfully applied will sustain the "*vis vitæ*" of the monster for another year.

The Doctor seems to have had an incontrollable itching in his fingers when he wrote his epistle, for, not content with showing up the delinquencies of the Provincial Association of which, as a member of Council, he might be expected to know something, but he goes out of his way to lecture the National Association upon matters of which he is, evidently, profoundly ignorant. He is however more harmless as an enemy than as a friend; and this is the very worst thing, I desire to say of him. He is very quarrelsome with the general practitioners because they seek to obtain a College for themselves: no wonder "Othello's occupation's gone" immediately the general practitioners achieve their object. The Doctor shews the instinct of his class; nothing more, when he declaims upon the propriety of there being but two grades in the profession, he should inform us, also to which grade he intends to attach the general practitioners, and how he means to invest them with their due rights in that grade. I assume that he would associate the general practitioners with the College of Surgeons. Wiser and better men, with all due submission to the Doctor, have said the same thing and tried it too, and with no better success than to draw upon themselves insult, derision, and contempt. This kind of counsel from quasi friends has become obsolete, because the profession have fully tested its uselessness. If Dr. Bell have nothing novel to suggest, he should in mere decency refrain from dishing up a banquet of "stale events.'

I am, Mr. Editor,

Your most obedient servant,

CRITO.

*** Our Correspondent, whose name we possess, if too hard on our contemporary—a journal as faultless as under *its* circumstances *any* journal could be, does but justice—a very merciful justice—to Dr. Bell: a declaimer as loud-sounding as he is inharmonious to the ears of sense. This sensible physician evidently does not comprehend the elements or uses of the association of which he is a committee-man. What absurdity to expect public union, prudent energy or combined *political* action in an association attracting members as a mere publishing club! An association made up, too, of physicians of all colleges and universities, abroad and at home, of surgeons, pure, or the contrary, and of general practitioners of all degrees of qualification! Well, indeed, may "it gain no ground!' The blunder of the scheme is so monstrous, that the obtuseness must be fatuous which does not see it. But the fact is in the medical profession, the *cacoethes scribendi* is at once universal and ungovernable.

There is a mania for seeing people's selves in print.

Scribimus docti indoctique passim."

Hence, of all professions ours is the most overrun and *infested* with book-making, and journalism; and this in the face of the fact, that medical men are neither great readers nor great buyers. We recollect an elaborate argument supported by statistics, in one of the reports of the Provincial or National Association, to prove that there were not at the outside, more than 7,000* English medical men in the kingdom; yet there are more books and journals annually printed than five hundred thousand of a public would suffice to pay for. We say it strongly and advisedly, therefore, that the heads of the provincial association ought to be ashamed to dabble in petty attempts at needless and inefficacious hebdomadal journalism. Personally, it is a mean ambition for them; publicly it places in jeopardy all the high ends for which the society is formed; and they are responsible. The payment of five or six hundred pounds a year to government for what when a thousand pounds more are spent on it, is worth, and must ever be worth, little more than as much waste paper, is an absurd waste of money, which has been given grudgingly, and is needed in a thousand useful directions excessively. If the respectable heads of this large society cannot get rid of such trumpery views of public conduct, by whomsoever forced on them, and manage the association efficiently for the only two ends for which an association need exist, viz..—for improving the state of the profession socially, and securing its amelioration politically, the honourable and manly thing for them will be to wind up and dissolve forthwith.—ED.

MR. PRESIDENT LAWRENCE.

SIR,—As the representative, and guardian of the interests and respectability of the medical profession, I venture to direct your attention, and that of my brother practitioners, to the recent insult, *so tamely borne*, from the Council of the College of Surgeons in the appointment of Mr. Lawrence as President! "*The geese*," I beg their pardon, members, are doomed to be plucked, and their placid manner of bearing it has been thought remarkable. The last feather perhaps is not yet reached, although, certainly, it has become wondrous white. As I have no wish it should be shown on my part, I cannot do otherwise than express my protest at the unworthiness of the object that now fills the President's chair, of what (per se) is a noble institution. Are our principles and respectability thus to be treated with contumely, *by those* who ought to be, and are professedly, the protectors of our interests? The *conscience* of *one* must already tell him that he has sinned against knowledge, and that whatever defence he makes must contradict his own internal conviction. He has acted in direct contradiction to those laws which he has sworn to administer faithfully, and protect inviolate. I recommend to the consideration of the general practitioner that he do not again meet in consultation one of the present council; by these means he will show them he does not intend quietly to submit to oppression or insult. "The geese" who were providentially ordained to save the capitol, may save the college from its rulers. I would put these questions to the president—"whether the members love him;" "whether they have confidence in him;" or being affected with admiration towards him, "whether they think he deserves honour!" Can he imagine that his late conduct is tolerated by an intellectual profession, or that their silence may be construed into something like apathy or approval of it? if so, let me assure him that he makes a mistake. Had he judged of what course would have been truly honourable to himself, he would have declined *at the present moment* the vacant chair. Common respect for the council, if he had none for the profession whom he was about to represent, should have taught him better things. Is it not *revolting* that presidencies should be thus obtained, and that vacant seats should be occupied, under the most painful circumstances; that there should exist men, *and big men, too*, who are ready, cash in hand, to purchase from those who are not proof against the extremity of distress though reproached by feelings, too naturally connected with despair? MEDICUS.

MR. WAKLEY AND HIS FIDUS ACHATES.

SIR.—In reading the evidence of Mr. Erasmus Wilson, before the coroner at Hounslow, on the flogging case, I was painfully struck with the incorrectness, to say nothing of the animus, of the witness, displayed in that evidence.

Mr. Wilson is not a fair witness in this case, for the following reasons- Mr. Wilson and Mr. Wakley have been intimately connected for several years. Mr. Wilson was tutor to Mr. Wakley's son, Thomas, Junior. Mr. Wakley orders Mr. Wilson (his intimate friend,) to examine the spine of the dead soldier, whose body had been twice examined before, informing him at the same time, that he (Mr. Wakley) had a notion there was something wrong with the spine, which the other surgeons did not find out.

Mr. Wilson obeys orders, and incontinently discovers a mare's nest, as much to please the Coroner as for the purpose of putting himself at the inquest. The mare's nest is called by Mr. Wilson "a pulpy softening of the muscles," which morbid condition he claims the honor of being the first to discover.

This pulpy state of muscle is nothing else than decomposition of the parts, infiltrated by blood from gravitation, in a body which was dead for more than a fortnight before Mr. Wilson opened it, and in the hottest weather known for forty years. In the course of his evidence Mr. Wilson congratulates himself and the jury on—what do you think?—that he discovered the real cause of death?- No such thing; but that his *books are out of print!* and then proceeds to edify the jury with his medical pedigree, with the sanction of the Coroner. What had all this to do with the case in point?

If Mr. Wakley wanted to puff his friend, he should confine himself to the pages of the Lancet, where, by the by, he abuses all puffery and quackery unconnected with himself, and not stultify the profession, and impede justice by such silly puffing twaddle as passed between himself and his surgeon on Monday last.

The whole case is evidently a got up one—Mr Wakley wants to puff himself with the public as a *friend of the poor*; and his friend Mr. Wilson wants to puff himself into practice. I am by no means a supporter of the flogging system, for I think it is brutal and barbarous; but, in the spirit of fair play and truth, let not an innocent and worthy officer be sacrificed in the attempt to put it down by a popularity-hunting Coroner and a foolish surgeon. It is abundantly clear from the medical evidence that the cause of death in the case of the soldier White was not the lash, and even Mr Wilson's evidence (although shaped to order) goes to prove this fact.

That the effects of the lash penetrated through the mass of muscle (very considerable in the thinnest subjects) which flanks the spine, produced old adhesions, inflamed the pleura, the heart, its valves, carneæ columnæ, and leading arteries, besides engorging the left lung with serum, is an assumption so truly ridiculous in a medical point of view, that were it not for the approaching general election, and the dearth of *popular* subjects for electioneering purposes, I should be inclined to think the Hon. Member for Finsbury demented, and his garrulity at the Hounslow inquest, a melancholy exhibition of an effete intellect.

July 28th. FAIR PLAY.

TEMPERANCE AND SKIN DISEASE.

[To the Editor of the Medical Times.]

RESPECTED FRIEND,—The following passage from the Lecture of James Startin Esq., Surgeon to the London Cutaneous Institution, has at least awakened my curiosity. Speaking of Acne Rosacea, he says, "But in justice to those afflicted with this often misjudged disfigurement, I must beg you will observe, that the intemperate are not its only victims, for the water drinker is by no means exempt; indeed I have fancied cases of acne rosacea have multiplied since the introduction of teetotalism, and this to an extent that has occasioned my regarding that species of abstinence as one of the predisposing causes of that disease, arising, probably, from the disorder it induces in the digestive organs, deprived, perchance suddenly, of an accustomed stimulus."

I am glad to find that the attention of James Startin has been turned to the relation between alcoholic liquors and cutaneous diseases, which is perhaps more intimate and extensive than has been generally supposed; but it is rather a bold move of the Lecturer to attempt to shift the disease in question from the class which has hitherto suffered the affliction, and fasten it on Teetotallers.

Perhaps I should scarcely have noticed this paragraph had it not appeared to me a serious thing to promulgate in a lecture to a class, the mere fancy, for he calls it by no higher name, that acne rosacea has increased to such an extent since the introduction of teetotalism as to have occasioned his regarding that species of abstinence as one of the predisposing causes of that disease. He attempts to account for it, from "the disorder it induces in the digestive organs deprived, perchance suddenly, of an accustomed stimulus." I must confess myself sceptical as to any disorder of the digestive organs being a necessary consequence of simply abstaining at once from intoxicating liquors, but that it should occur to such a degree as to induce acne rosacea, and to such an extent as to materially affect the prevalence of that disease, is at least highly improbable, unless indeed the complaint has assumed entirely new characters. Whenever disordered digestive functions supervene on total abstinence from alcoholic liquors, it is probable that careful observation would detect other causes, as errors in diet, having no necessary connection with abstinence; sometimes the drinking of flavoured, coloured, syrups sold under the name of temperance drinks; or immoderate quantities of coffee, tea, soda water, lemonade, &c., taken under the idea of a substitute for the liquor which has been given up. Yet even these dietetic errors are scarcely sufficient sensibly to increase the number of cases of acne rosacea, if indeed they had the power to induce a single instance.

I have paid attention to the health of Teetotallers from the commencement of the temperance movement. I have known moderate drinkers and hard drinkers; malt liquor drinkers, and wine and spirit drinkers, abandon their use at once, and I am not aware of a single instance in which the digestive powers were impaired or the general health injured from that cause alone. It is indeed highly improbable that any disorder should arise from withdrawing an unnatural stimulus like alcohol, on the contrary, the stomach generally seems delighted to get rid of so troublesome a guest, and performs its duty with alacrity and vigour.

When I speak of no injurious consequences resulting from the change from drinking to abstinence, I mean entire abstinence, at once, from all distilled and fermented liquors, without any exception or reservation whatever, the almost immediate effect of which is increased buoyancy of feeling. improved appetite, especially for breakfast, far more enjoyment of the flavour of plain food, less inclination for seasonings and condiments, less thirst, and yet a higher relish for pure good water. The results, however, will not be the same if the alcohol is attempted to be withdrawn gradually, either by diminishing the quantity taken at once, or increasing the intervals. A very little taken either occasionally or at stated intervals is sufficient to keep alive the alcoholic appetite, to tantalise and fret the stomach, and mar the whole experiment. Dr. Bateman says, "the perfect cure of acne rosacea

is, in fact, seldom accomplished, for whether it originate in a strong hereditary predisposition, or from *habitual intemperance* the difficulties in the way of correcting the habit of body, are almost insurmountable." Yes, the difficulty is great and altogether insurmountable on any other principle than that of entire abstinence at once, which would be found far more easy and practicable, as well as more efficacious in correcting the habit of body than any measures whatever short of this.

Good, Bateman, Plumbe and other authors all attribute acne rosacea to the intemperate use of intoxicating liquors. Plumbe has only known one case of this disease that was not connected with the habit of *hard* drinking. Dr. Todd in the Cyclopædia of Medicine says, "It is not however to be forgotten that acne rosacea *sometimes* appears in people of the most sober and temperate habits;" this, sometimes, shews that its occurrence in sober and temperate habits was looked upon as an exception to its general appearance. He also says ' it sometimes shews itself in conjunction with a state of exhaustion and general debility." If this exhaustion and debility could be shewn to prevail more amongst teetotallers than amongst habitual drinkers of any grade, it might favour the idea of some necessary relation between abstinence from intoxicating drinks and the prevalence of acne rosacea. Till this is done I apprehend some other cause than teetotalism must be sought to explain the multiplication of cases of that disease.

I am, very respectfully,

JOHN FOTHERGILL, M.R.C.S.

Darlington, 2nd. Mo., 28th, 1846

A QUERY.

SIR,—I am anxious to qualify myself for the specialty of witness to coroner's inquests; being on the point therefore of publishing a work on ——, a subject on which I am profoundly ignorant, and another on ——, which is now being written for me, at so much per sheet, I should be much obliged if you could help me to the name of some literary carpenter, who can knock up a discovery or two to order, on moderate terms.

F. R. S.

P.S. Are you acquainted with Mr. Erasmus Wilson? What are *his* terms?

GOSSIP OF THE WEEK.

ROYAL COLLEGE OF SURGEONS.—Gentlemen admitted Members, on Friday, July 24th, 1846, viz.: Messrs. T. H. Marshall, O. E. P. Chard, H. S. Saunders, W. L. Grundy, H. Sillifant, J. Rowe, and J. Bolton.

Admitted, Monday, 27th: Messrs. J. Olguin, T. Hooker, T. P. Davis, E. M. Teame, A. Y. Kayat, D. N. D. Basu, G. C. Seal, B. N. Rose, W. R. Black, M. Johnson, R. Nichol, R. D. Ball, W. Cross, W. S. Hill, and J. Spurr.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen were admitted members of this college on Friday, the 17th inst., viz., Messrs. C. O. West, R. J. Squire, W. L. Norris, G. D. Haslewood, W. H. Colborne, G. C. Leather, J. M. A. T. Croft, J. E. Wood, E. Fletcher, C. Nattrass, C. Peskett, and J. Nuttall.—Admitted Monday 20th. H. Leskett, W. S. Stiven, G. Hawksford, J. Yates, J. Kempthorne, G. H. P. Sparrow, C. R. Matthew, W. Knowles, H. Hides, J. Hooper, and J. J. Roughton.

WESTERN GENERAL DISPENSARY.—Dr. J. Hennen, has been appointed physician to this Institution.

APOTHECARIES' HALL.—The following gentlemen were admitted licentiates on the 16th July, 1846:—Charles Rooke Prance, Benjamin Miller, Walter Youge, Robert Smart, John Foster, Edward Cripps, Robert Niblett, Joseph Samuel Davies.

ELECTION OF COUNCILLORS.—A large meeting of Fellows took place on Tuesday last, in the Theatre of this College, for the purpose of filling up the vacancies occasioned by the resignations of Messrs. Anthony White and George Gisborne Babington. The chair was taken at three o'clock, by Mr. Lawrence, the President, supported by Messrs. Travers and Stanley; the election was as usual by ballot, the President declared Mr. Richard Wellbank re-elected, and Mr. Richard Dugard Grainger, the Lecturer on Anatomy at Saint Thomas's Hospital, and Mr. James Luke, Surgeon of the London Hospital, Members of the Council.

APOTHECARIES' HALL, 23rd July, 1846,—Septimus Lowe.

OBITUARY.—On Friday, the 10th instant, at his residence, in Stafford-street, Liverpool, aged 39, Mr. James A. Day, surgeon.

OBITUARY.—Dr. Souberbielle has just died in his 92nd year. He was the pupil of the celebrated Frere Come. M. Le Conseiller Domingos Ribeiro dos Guimaraes Peixoto, Baron of Iguarassu, first physician to H.M.H., the Emperor of Brazil, died on the 22th of April last. M. Beuzenbey, formerly professor of chemistry at Dusseldorf, died recently aged 72.

OBITUARY.—On the 4th inst., in the gaol of Appleby, Mr. James Towers, M.D. Deceased had been upwards of twenty-four years a prisoner in Appleby gaol. He was tried at the spring assizes, 1822, for the murder of his wife, and sentenced, on the ground of insanity, to be kept in strict custody during his Majesty's pleasure. On the 17th inst, at St. Lawrence, Thanes, Sir Thomas Grey Knight, M.D., F.R.S., and for more than twenty-five years magistrate of the county of Kent and the Cinque Ports.

On Sunday, the 26th inst., in the 34th year of his age, deeply lamented, Arthur Tibson, Esq., surgeon, of Spring-street, Sussex-gardens.

WAR-OFFICE, July 24th. 3d Foot.—Assist.-sur. George Fenton Cameron, M.D., from the 63d Foot, to be assistant-surgeon, vice Gordon, promoted on the Staff. 63d Foot: Josias King Carr, M.D., to be assistant-surgeon, vice Cameron, appointed to the 3d Foot. Royal Lanarkshire Militia: John Thomson, M.D., to be surgeon, vice Anderson, deceased. Forfar and Kincardine Regiment of Militia: assistant-surgeon Alexander Dickson, M.D., to be Ensign, vice Richardson, resigned.

NAVAL APPOINTMENTS.—Assistant-surgeons: Alfred Jackson (additional acting), of the Victory, to the Raleigh; J. C. Murray, M.D., to the Victory.

A commissary of the French police has lately seized a large quantity of tainted meat belonging to some butchers in Paris. This meat would have been sold to the keepers of small eating houses to form the food of the lower classes. About 2,000 weight of it has been sent to feed the beasts in the royal menageries.

EXAMINATIONS BEFORE THE FRENCH FACULTY OF MEDICINE.—In 1844, the faculty of medicine of Paris, on the proposition of the dean, passed a resolution requesting the minister of instruction to obtain from the chambers an annual salary of 1,000 francs each, for the *Agrégés* (assistant professors) of the faculty of medicine. In thus endeavouring to improve the position of the *Agrégés*, M. Orfila, the dean, proposed, at the same time to confer on them new offices in examinations and teaching, and thus to elevate a post already highly distinguished. After frequent requests to both the present Minister of Instruction, and his predecessor, M. Salvandy has demanded of the Chambers the sum of 50,000 francs, which has been granted. Thus, after the 1st of January next, the *Agrégés* will receive each a fixed annual salary of 1,000 francs, independently of their present share in examination fees, which was voted to them in 1823, and of their remuneration when called on to perform the duties of professor. In Paris this remuneration amounts to 2,000 francs, when an *Agrégé* is required to deliver the whole of the course of a professor who is absent or ill.

APPOINTMENTS.—Surgeon; C. Coffey, to the Recruit. Assistant-Surgeons: C. Grier, to the Cherokee; J. Forbes, to the Mohawk.

WAR OFFICE, July 11—11th Regiment of Foot: Assist. Surg. Richard Dane, M.D., from the 29th Foot, to be Surgeon, vice West, deceased.—29th Foot:—Alexander Mackay Mackay Macbeth, gent. to be Assist. Surg., vice Dane, promoted to the 11th Foot.—Hospital Staff: To be Assistant-Surgeon to the Forces, William Westall, M.D., Thomas Parr, gent., George Frederick Fletcher, gent.

KENT MEDICAL BENEVOLENT SOCIETY.—The fifty-ninth anniversary meeting of this Society was held at Canterbury, on Wednesday, the 8th of July; F. H. Sankey, Esq., President Allowances for the ensuing year were granted to nine applicants, amounting together to the sum of 215l. The gratifying announcement that the permanent stock of the society amounted to six thousand pounds, three per cent. consols, led to the consideration of the propriety of extending its benefits, and a resolution to the following effect was unanimously adopted:—"That a general meeting may grant relief under circumstances of peculiar distress, to any member or his family, at any period after his joining the society, provided he has done so previous to his attaining the age of thirty five years, and that two-thirds of the members present approve of such grant." An annual subscription of one guinea for ten years, or the payment of the sum of ten guineas, will still be requisite to entitle to the benefits of the society, by any person who may join the society after he has attained the age of thirty-five years. Assistance to the amount of nearly eight thousand pounds has been afforded by this society to thirty-four members or their families since its institution.

The quarantine question will be seriously discussed at the Scientific Congress at Genoa. It has been admitted, after some consideration, among the class of most important subjects.

The Emperor of Austria has just named a commission to arrange the building of a new asylum for the the insane of Vienna. The sum of 600,000 florins has been allotted to meet the first expenses

The prizes were distributed to the pupil-midwives of the Parisian School of Midwifery on the 23rd of June. M. the Viscount de Montmar presided at the ceremony.

A Hungarian has discovered a means of preserving cattle from the contagious typhus which has given rise to such lively disquietude to the breeders of a great part of Europe, especially France and Germany. The means is simple and easy. It consists in inoculating the animal to be preserved with the saliva of one of those labouring under the disease. This inoculation is said to be as efficacious as that of vaccine in preventing small-pox in the human subject.

MORTALITY TABLE.

For the Week ending Saturday, July 25, 1846.

Causes of Death.	Total.	Average of 5 summers.	Average of 5 years.
ALL CAUSES	1003	898	968
SPECIFIED CAUSES	991	892	961
Zymotic (or Epidemic, Endemic, and Contagious) Diseases ...	308	201	188

No. 358. SUMMARY. [A]UGUST 8.

PROGRESS OF MEDICAL SCIENCE,

INCLUDING CHEMISTRY AND PHARMACY.

France.

[From our own Correspondent.]

ACADEMY OF SCIENCES.

Meeting of July 27, 1846; M. MATHIEU in the Chair.

DIGESTION OF ALCOHOLIC FLUIDS.—By Messrs. Sandras and Bouchardat. In their previous physiological researches, the authors inquired into the digestion of fat, saccharine and feculent principles, and their share in nutrition; fermented liquids still remained to be studied, and the following are the results of the investigation they have instituted for the purpose of completing the history of what they call "the food of the organs of respiration." During the first part of the process of digestion fermented fluids are not dissolved, but are merely diluted by the saliva, gastric juice, and the other liquids which occupy the cavity of the digestive viscera. As M. Magendie had already shewn, the absorption of the alcoholic fluids is performed by the venous orifices in the stomach, and the lacteal vessels have no share in this action—a circumstance proved by the facts, that after the ingestion of alcohol, not a particle of that substance can be detected in the chyle. The organs of secretion do not eliminate fermented fluids, a small portion of which only, is evaporated from the pulmonary surface. When excessive quantities of spirituous liquids have been admitted into the circulation their first effect is to prevent the arterial blood from acquiring its florid colour, and to expose the patient to asphyxia. The oxygen largely introduced into the sysmte during the act of respiration may often convert the alcohol into water and carbonic acid; but in several cases an intermediate product, acetic acid, has been obtained. Fermented fluids, very soon pass entirely out of the body; and their elimination is more speedy when they have previously been in combination with dextrine or glucosis.

FISTULOUS GASTROTOMY.—M. Sedillot presented the first part of a memoir on fistulous gastrotomy. The author gives this name to an operation, which consists in establishing a permanent opening in the parietes of the stomach, in order to furnish an artificial passage for food, in those cases, in which, the œsophagus being completely closed by a permanent stricture, the patients necessarily die of inanition. In this first part of his work, M. Sedillot gives a summary of the considerations on which he founds the indications and the probability of success of the operation he proposes. These considerations are based on cases of cure of wounds in the stomach, and on the existence of permanent gastric fistulæ being compatible with life; on the possibility of producing directly a permanent fistula of the stomach, and on experiments made on animals. Among the different questions which presented themselves for examination, the author considers the following: 1st, Will food introduced directly into the stomach, through a fistulous opening, be retained by the organ? 2ndly, Will it be digested? 3rdly, What alterations in the composition of the chyle, and, consequently, in nutrition, will be caused by the absence of mastication, of insalivation, and of the action of the pharingo-œsophageal mucus, and by the presence of the fistula? 4thly, By what means can these accidents be partly or entirely relieved, if found to exist? He then gives the following considerations on each of these questions:—1st, Cases in which gastric fistula has occurred show that the patients are able easily to close the orifice, by the use of tents, bandages, or metallic bodies of a proper size and shape. Most of these patients enjoyed good health, and the food and drink never escaped involuntarily from the wound. If this be the case in accidental fistulæ, at first of considerable size in many cases, the closure, by a fit instrument, will be very easy in fistulæ made by operation. 2ndly, A fistula being formed, and capable of being opened or shut at pleasure, it is clear that the food, reduced into a pap or semi liquid state, will be carried into the stomach from above downwards, and that it will thus fill the organ. But will this viscus reduce it into chyme? No doubt can exist on this point, because we daily introduce food into the stomach through an œsophagus bougie. What difference can the defective insalivation and mastication of the nutriment produce? Mastication is a mechanical trituration, easily performed artificially; insalivation, therefore, only remains to cause defective nutrition. The author, in conclusion, seeks to prove, by considerations founded on pathology and human physiology, that fistulous gastrotomy is an operation well founded, both in theory and fact.

M. Serres wished to inform the meeting, on the occasion of this paper, that having been much occupied in considering the horrible condition of patients affected by an organic disease of the œsophagus, which prevents the introduction of food, he had conceived the idea of an operation similar to that described by M. Sedillot; but that as he had not had an opportunity of putting it in practice, he had avoided mentioning his discovery to the Academy. M. Serres congratulated M. Sedillot, on suggesting the same idea. The object of the present paper being something of the same nature as that in which M. Maisonneuve some time since proposed a new method of invagination for the relief of intestinal strangulation, M. Serres proposed that it should be sent to the same commission.

M. Flourens observed, that the author being already a corresponding member of the Academy, there was no occasion to refer his memoir to a commission. An abstract of it would be inserted in the *Comptes Rendus*, when the commission would notice it.

[This proposition was agreed to by the Members present.]

HOPITAL DE LA CHARITE.

CLINICAL LECTURE BY PROFESSOR VELPEAU.

Polypus of the Nose and of the Ear.—You have lately seen in the wards, a case which was operated upon and in which surgical interference was rendered very difficult from the presence, at the same time, of fibrous polypi in both nasal cavities and in the pharynx. The impossibility of excision and ligature obliged us to have recourse to another method, that of crushing, which performed in the nose; after a few days the polypus of the pharynx was spontaneously detach[ed]. [To] this case we now call your attention; it is important, because it might serve to establish a new treatment for polypus. In the throat, extirpation is a difficult and dangerous operation, which may be followed by hæmorrhage, a severe accident in that region. The method we employed in the case just referred to—crushing—might be likewise applied to uterine polypus. When the latter is crushed it is also cured, gangrene bringing on its separation from the womb. This is also the case when the tumours occupy the nose: in a word crushing is a safer plan for the patient and a more convenient method for the surgeon. This of course refers only to fibrous polypus.

We also have in the wards a case of vegetations of the left ear. In this region polypi are not very common; they deserve besides, to attract some degree of attention because they are usually symptomatic of another disease, and are more frequently connected with an affection of the cavity of the tympanum than of the membrana tympani. They may be cellular, fibrous or cancerous. The first form, the cellular polypus, depends often upon caries of the petrous bone, and its prognosis is of course therefore, [ext]remely serious. In this respect a great difference must be made between the polypus of the nose and that of the ear. We do not find it produced by caries in the nasal cavities, whereas this alteration often occasions vegetations from the meatus auditorius, and is followed with abscess which sooner or later terminates in cerebral disorder. The woman who presents polypus of the ear, has always complained of hardness of hearing; sharp pains have been felt in the organ, and a discharge has for some time existed. At present, a greyish production may be distinctly seen in the ear, and its surface is free from any trace of suppuration or hæmorrhage, a fact which may lead us to admit, with some reserve, that the origin of the disease lies in the membrane, and not in caries of the bone. Long dissertations have been written on the subject of aural polypi; the ear is a region which has given rise to a family of special pathologists, who have found it advantageous to their own purposes to write long books on trifles and to say many useless things. In the ear almost all tumours, whatever their nature, assume the shape of polypi; this circumstance is clearly due to the form of the duct which, communicating with the pharynx by the eustachian tube, present besides a mucus mem-

brane, nerves and vessels, and also with the mastoidau cells and labyrinth, is occupied by tumours as different in nature as they are in origin. When caries is suspected, it is at first useless and imprudent to examine the parts with a probe; when the instrument can penetrate into the cavity of the tympanum, it may lacerate one of the three delicate little muscles which are attached to its bones and, coming into contact with these, may furnish, on account of the extreme thinness of their periosteum, an erroneous sensation which could readily be mistaken for that given by caries and if that sign were consulted, a false diagnosis might be the consequence.

Poisonous effect of Belladonna.
(From the Repertoire de Pharmacie.)

Case.—M. X. was seized on June 23, 1845, with a slight rigor; which had for two or three days been preceded by headache, sore throat, and pain in the right elbow. The patient aged 21, was of a vigorous, healthy temperament, and had lately had a slight blennorrhagic discharge, which had yielded to the balsam of copaiba. On June 24, two physicians met in consultation, and they agreed to exhibit extract of belladonna in *grain* doses every hour. During the following day the patient took 18 grains of the extract, and a mild form of delirium having supervened, the medicine was suspended. Three other pills were however, given at more distant intervals, during the ensuing day, when two attacks of violent mania occurred, the patient becoming dangerous to approach, and being at the same time affected with the most singular hallucinations. The attacks were preceded by a condition, which the medical attendants compare to angina pectoris, and caused the greatest apprehension. The rheumatic affection of the elbow joint had not been in the slightest degree improved by the treatment. During one of the attacks, life even seemed to have departed, a deep fainting fit having occurred. This state of unconscious and violent insanity lasted for 24 hours, after the last dose of medicine, when the patient took some strong coffee, and gradually recovered, the rheumatism not being however modified.

In this case, the dose of the drug seems to have been unwarrantably large. Several instances of acute rheumatism are on record, which have been rapidly cured under the influence of the extracts of the Solaneæ tribe: but in the case above related, it is not even certain that the physicians had to do with acute rheumatism. The circumstance of the disease attacking only *one* joint—and that, a few days after the cessation of a gonorrhœal discharge, points in a very marked manner to blenorrhagic arthritis; on the other hand the extracts were never recommended by Dr. Lebreton, the promoter of the method, to be used in such immense doses: that practitioner exhibits only one-fourth or one-fifth of a grain of the extract of stramonium, or of hyoscíamus, or of belladonna every hour—the medicine should be continued until incipient delirium appears, and then its exhibition slackened. In this manner no danger attends the treatment; and if success be not certain, still the physician cannot be accused of having placed in jeopardy the life or reason of his patient.

Dan. M'Carthy, D.M.P.

Germany.

Obliteration of the Œsophagus, with Communication of the Lower Part of the Canal with the Trachea.—Professor Levy, of Copenhagen, relates two cases of this malformation, in the *Neue Zeitschrift fur Geburtskunde.* The first case was that of an infant, apparently healthy when born, but which was unable to suck, and rejected everything that was administered to it. The day after birth a catheter was introduced into the œsophagus, but was arrested at a depth of about four inches. Milk injected through the catheter was immediately returned by the nose and mouth, producing symptoms of suffocation. Closure of the œsophagus was accordingly diagnosticated, and some broth was injected into the rectum. At the period of its birth, the infant weighed six pounds and a half; forty-six hours afterwards it only weighed five pounds and a half; fifty-eight hours after, it weighed five pounds and a quarter; seventy hours after birth, it weighed five pounds and an eighth; eighty-two hours after, five pounds. The infant died eighty-three hours after birth. The child lost, therefore, during four days, one pound and a half in weight, half-a-pound being the loss during the last two days. The urine and fæces presented a natural appearance; they were passed at long intervals, and scarcely exceeded the weight of the broth injected. On post-mortem examination, the upper portion of the œsophagus was found to terminate in a cul-de-sac, in which the catheter introduced by the mouth, was arrested. This sac was about an inch long, and twice the size of an ordinary œsophagus. The structure of the muscular fibres presented nothing abnormal, except that they converged towards the truncated extremity of the tube. The inferior portion of the œsophagus was connected with the trachea and larynx; so that a catheter introduced through an incision in the cardiac extremity of the stomach, passed easily through the trachea and larynx into the mouth. The communication between the trachea and the œsophagus took place about a line below the bifurcation of the trachea, and was formed by an oval opening, three lines long and one line wide. The posterior wall of the air-duct and the respiratory mucous membrane were continuous with those of the digestive canal. In the second case, the fœtus was born before the full period of gestation, and died immediately after birth. In this case, Professor Levy found besides several malformations in the region of the pelvis; that the upper part of the œsophagus terminated in a cul-de-sac, and that the lower communicated with the right bronchus. The communication of the tube with the trachea differed from that in the former case, inasmuch as the œsophagus contained some cartilaginous rings in a part of its extent. With the exception of the case of Martin, republished in the pathological anatomy of M. Andral, Professor Levy has never seen any other examples of this malformation than those just related. These cases support the opinion of those who regard monstrosities as arrests of development.

Report of the Cases in the Lying-in Hospital of Gottingen during the Years 1841, 1842, 1843, and 1844.—Dr. Siebold, in the *Neue Zeitschrift fur Geburtskunde*, gives a statistical account of the practice of the Gottingen Lying-in Hospital. During four years, 461 accouchements took place, of which six were twin cases, making the number of births 467. 240 of these were boys, and 227 girls. 229 deliveries took place between the hours of six in the morning and six in the evening, most of them occurring during the early part of the day; and 232 between the hours of six in the evening and six in the morning, the greater number being after midnight. The longest duration of any labour was eighty-four hours; the shortest, three-quarters of an hour. Of the 467 births there occurred:

Natural labours	422
Turning cases	4
Footling cases	3
Forceps cases	36
Perforation of the cranium	1
Cæsarian operation	1
	467

All the women delivered by the forceps recovered, and two infants only were born dead. It is remarkable that, generally speaking, in these cases, the accoucheur placed himself by the side of the woman, without disturbing her from her natural position in the bed, either to apply the instrument, or to assist in the extraction of the child. The four children delivered by turning died. Of the three foot presentations, one infant survived, the second died, and the third was in a state of decomposition previous to labour. Artificial labour was brought on prematurely in one woman, who had been previously twice delivered by means of craniotomy. The infant lived a few hours only. Craniotomy was performed on one infant in consequence of contraction of the pelvis, the child being evidently dead before the operation. The cæsarian operation was indicated in one case in consequence of osteomalacia, although the child was evidently dead. The mother died on the fifth day after the operation. Artificial extraction of the placenta was necessary in eleven cases, on account of hemorrhage, and was performed in all cases with success. It was necessary to detach it four times, once on account of adhesions produced by calcareous concretions. Twenty-two children were born dead, and twenty-one died soon after birth. Ten women died; six of peritonitis, two of nervous (?) fever, one of delirium-tremens, and one from the effects of the cæsarian operation. Out of 467 deliveries, the head presented in 453; the right parietal protuberance being the presenting part in 311, and the left in 123. In 434 cases, the lesser fontanelle was in advance; and if, at the commencement of labour, it had been placed posteriorly, it was found in advance at the moment of the expulsion of the head. In eight other cases only the fontanelle remained posteriorly, and the rotation of the head did not occur. M. de Siebold always found the sagittal suture placed in the oblique diameter of the pelvis and the fontanelles directed towards the sides, even at the moment of passing the vulva. Presentation of the face was only observed once, in which case the labour terminated naturally. Of 1400 labours, which M. De Siebold has attended in the Lying-in Hospital since 1833, face presentation has only occurred three times. In six breech presentations, the delivery terminated without assistance, and the mother and child both did well. In one case of breech presentation, it was necessary to make some traction to deliver the head, and the child died. In a second case, assistance was required in the delivery of the shoulders: the child survived. Out of five footling presentations, manual assistance was necessary three times, in order to extract the child. In one of these cases, the child was born alive; in the second, it died during labour; and in the third, it was born in a state of putrefaction. In the two footling cases left to nature, one child did well, and the other was born in a state of putrefaction.

Ovarian Dropsy.—Dr. Schreiber reports four cases of ovarian dropsy, in the same journal. He gives the following resumé of the cases: The patients were aged respectively forty-one, sixty-seven, thirty-six, and thirty-nine years. Menstruation continued regular in the woman, aged thirty-six; it ceased soon after the commencement of the disease, in the woman of forty-one, and its suppression seemed to hasten the progress of the dropsy. The woman aged forty-one had been delivered of eight children; the one aged sixty-seven, of five; the woman aged thirty-six, of two; and the woman aged fifty-eight, of two. The seat of the disease was twice on the right, once on the left, and once on both sides. On the points of its development and duration, Dr. Schreiber says that the patient aged thirty-six suffered, at the age of twelve, from an abscess in the right ovarian region; notwithstanding this, she married, contrary to the advice of her physician, and at the age of thirty, several years after marriage, became a mother. After a laborious accouchement, a swelling appeared in the right side, but, after the escape of a large quantity of pus and serum by the rectum and vagina, she recovered, again became pregnant, was twice delivered easily, and aborted in a fourth pregnancy. In the patient aged fifty-seven, the disease commenced with hysterical symptoms at the age of forty-two. The patient aged forty-one suffered during pregnancy from severe colic, fifteen years before the positive diagnosis of the dropsy of which she died. The patient aged fifty-eight had suffered from cramps in her stomach, pains in the belly, and had one bad abdominal inflammation; she died at the expiration of eighteen months. In addition to the usual symptoms of dropsy, there were difficulty in passing urine and stubborn constipation, in three cases; and in one case there was vomiting of fecal matter. The patients were able to follow their usual occupations during the greater part of

the disease, and were only obliged to keep their beds a short time before death. Puncture, performed early, gave relief; but towards the close of the disease, it seemed to hasten death. The operation was repeated every six or eight weeks, and the quantity of fluid removed was usually about fifteen pints.

CÆSARIAN OPERATION.—Dr. Kunsemuller records three cases of cæsarian operation, in the same journal. In the first case, the patient was forty-one years of age, and had been previously delivered of six children; at the close of the seventh pregnancy, the cæsarian section became necessary. The child was extracted dead, and the mother died on the next day. In the second case, the patient was forty-three years of age, and had had ten children before. The pelvis became deformed by osteomalacia, so that the cæsarian section became necessary at the expiration of the eleventh pregnancy. The child was dead, and the mother died on the sixth day. In the third case, the patient was thirty-eight years of age, and had been safely delivered of five children. She had been much exposed to want and misery, in addition to disease. Her pelvis became deformed, and at the sixth labour, the antero-posterior diameter was found diminished; however, the child was extracted, with some difficulty, by means of the forceps. At the end of the seventh pregnancy, osteomalacia had made so much progress, that the cæsarian operation was necessary. Both mother and child were saved.

ATTEMPT TO FORM A SCALE OF THE VALUE OF DIFFERENT SUBSTANCES IN THE ANIMAL AND VEGETABLE KINGDOMS, BASED ON THE PROPORTION OF AZOTE CONTAINED IN THEM.—Drs. Schlossberger and Kempt have published, in the *Archiv fur Physiologische Heilkunde*, a valuable paper with the above title, of which the following is a full abstract. The distinction of alimentary substances into plastic or azotised, and those serving for respiration, or non-azotised, is one of the great steps of modern physiology; all former attempts which had been made to classify nutritious substances, according to their more or less assimilable qualities, having failed, and not proving serviceable in forming dietetic rules.

Prout suggested that the more carbon any substance contained, the fitter it was to sustain life; but experience has since shown, that although all food should contain carbon, the presence of azote is indispensable, because the organism of animals cannot convert unazotised matters into azotised, although in constant contact with the azote of the atmospheric air, and of ammoniacal vapours. Still, however, Prout's scale was of service, inasmuch as it taught us the abundance of alimentary matters suited to purposes of respiration, which matters sustain so much the more easily pulmonary hematosis and animal heat, as they contain more hydrogen and carbon; such, for instance, as oils, fats, fecula, saccharine, and spirituous substances.

But the nutrient matters, properly so called, that is to say, those which serve to renew the blood and the tissues, are not the richest in carbon; those only which assist in the formation of cellular and fatty tissues, need contain much carbon; those destined to renew the compounds, called protein, should, on the contrary, contain much azote.

In general, those substances which contain much protein, are also strongly charged with phosphates, and the calculation of the proportions of these salts, in an alimentary substance, will probably also, hereafter, furnish a means of appreciating its nutritious qualities. This may be expected of the gelatinous substances amongst others.

As far as regards the alimentary nature of pure gelatine, it is now proved that this immediate principle is no more able to support life, when given alone, than any other. But, if animals fed on gelatine alone soon die, they do not support any better a regimen of any other single alimentary principle, however nutritious it may be, such as fibrin, albumen, sugar, fat, &c. Substances containing protein (albumen, fibrin, casein), and gelatinous substances (gelatine, chondrin), present the greatest analogy in the elementary composition; and they also are the most nutritious, when properly mixed; that is to say in plain language, that good broths and soups are the best food, as well for the healthy as for the convalescent and sick.

In a scale in which it is sought to arrange articles according to the quantity of nutriment contained in them, their relative digestibility cannot be considered; but it is very likely to happen that substances, poor in nutritious principles, may, on the contrary, be much easier of digestion than those which are richer.

All articles of food, as nature furnishes them to us, are mixtures pretty nearly alike; but the culinary art changes considerably their nutritive qualities. Thus a bromatological treatise on all kinds of meat would become an exceedingly complicated work. Up to the present time the assimilable property, that is to say, the richness in azote, has only been studied in certain vegetable products, especially in those which serve as food for herbivorous and graminivorous domestic animals.

Azote has been found in varying proportions in 100 parts, well dried, of each of the following substances, viz:, in

Rice	1·39
Potatoes	1·50
Turnips	1·70
Carrots	2·40
Rye	1·70
Maize	2·00
Barley	2·00
Wheat	2·20
Oats	2·20
Peas	3·80
Pulse	4·40
Beans	5·10
French Beans	4·50
White Bread	2·27
Black Bread	2·63
Artificially made Bread from Glasgow	2·17
Meal from Essex	2·17
Meal from Canada	2·21
Three species of agaricus respectively	4·60 4·20 3·20

To these tables M. M. Schlossberger and Kempt have added the results of their recent chemical researches on food, obtained both from the animal and vegetable kingdoms. In order to ascertain the quantity of azote contained in any given organic substance, they have adopted the method of Will and Warrentrapp, and weighed the ammoniuret of platinum, obtained by the combustion of 100 parts of the substance, when completely desiccated. Thus 0·438 grammes of human milk gave them 0·110 of ammoniacal platinum, equal to 1·59 of azote; 0·404 grammes of cow's milk, desiccated in a water bath, being much richer in azote, gave, by combustion, 0 241 of ammoniacal platinum, equal to 3·78 of azote.

Then, taking female milk as an equivalent, and marking it 100, M. M. Schlossberger and Kempt have given the following scale of the nutritious properties of different kinds of food.

Female Milk	100
VEGETABLE FOOD.	
Rice	81
Potatoes	84
Turnips	106

America.

TRISMUS NASCENTIUM.—Dr. Marion Sims, of Montgomery, Alabama, has published the following views on the pathology and treatment of the Trismus of new born infants, in the *American Journal of Medical Sciences*. After alluding to the universal presence of Trismus nascentium, under every variety of climate, and in every class of society, Dr. Sims proceeds to point out the various explanations which have been given of its causes. Of these Dr. Sims mentions irritation produced by retained meconium, cold and a vitiated atmosphere, excessive purgation, and costiveness, injury inflicted by cutting the cord with dull scissors, inflammation and ulceration of the umbilicus, pouring cold water on the head in performing the ordinance of baptism, the want of swathing or proper bandaging, the application of scorched linen or cotton to the navel, the smoke of burning wood, &c., as causes which have been proposed by different authors as exciting the disease. Dr. Sims then proceeds to give some cases of his own observation of which the following is an interesting one: Mr. Henry F. Stickney's negro woman, Patsey, aged twenty-six, of a light bronze colour, gave birth to twin girls, in July, 1844; this was her fourth pregnancy. On the 15th July, 1845, she was taken in labour at the end of her fifth pregnancy, and delivered about midnight of twin girls again. The birth of the second child was more tedious than that of the first. It was still-born, several minutes elapsing before respiration could be fully established. It was larger than its predecessor by a pound or more. They appeared to be doing very well, till Monday evening, the 21st (6th day after birth), when the second child refused to suck, became restless, and seemed to be unable to open its

mouth. On Tuesday it screamed and cried a good deal, appearing to be in great distress, its jaws still closed, with the addition of occasional attack of jerking or spasms. On Wednesday, about seven o'clock, P.M., Dr. Sims saw it for the first time, being forty-eight hours from the time of attack. Its body was rigid; legs straight and stiff, there being a just balance between the flexors and extensors which held them parallel; the toes everted and heels resting against each other. If the heels were separated and then let loose, they suddenly flew together like the blades of spring forceps. The arms were pinioned to the sides; the forearms flexed firmly at right angles; the hands clenched tightly; and the jaws closely locked. The least effort to extend the forearm caused great pain, and excited general clonic spasms. To open the hands was impossible. The expression of countenance was mild and serene, notwithstanding the great rigidity of the body and extremities, till the supervention of clonic spasms, which happened every few minutes, either spontaneously, or as the result of some external exciting agent, such as sound, motion, or the alighting of a fly on the face, when the whole frame seemed to become more rigid, the hands more tightly clenched, with a quivering motion, giving the child the appearance of shaking the fist; the jaws more closely locked, the head jerked backwards; the lips compressed; the angles of the mouth widely retracted; the eyelids spasmodically closed; the cheeks elevated, thus giving the face a most horrid, sardonic grin; and all accompanied with a pitiably mournful, whining cry. This aggravation of symptoms, lasted for a few moments, passing off to give place to the former calm expression of countenance, though not attended by any relaxation of the muscles of the body and extremities. This scene of comparative tranquillity lasted but a short time, from three to fifteen minutes, and then the clonic spasms as already described again came on. Deglutition was somewhat impeded, but not suspended. The condition of the pupils could not be ascertained, in consequence of spasms being excited by any effort at separating the lids; respiration greatly accelerated; bowels costive. It had taken syr. rhei., magnesia, and occasionally tr. opii, but with no effect. Ordered a warm bath, calomel, oil, and enemata. On the next day (Thursday) the child was worse; all the symptoms being aggravated. An antispasmodic was ordered. The child rested better, but on the following morning (Friday) he was much worse, being quite unable to swallow, the spasms more frequent, and the general rigidity greater. Dr. Sims now commenced experiments on the reflex action of the excito-motory system.

To show the great rigidity of the frame, he caught hold of the feet and raised the whole body without flexing the thighs on the pelvis. At last he ran his hand under the head for the purpose of elevating the body in the same way, when he immediately detected a remarkable irregularity in the feeling of the bones. The child had laid during the whole of its illness exactly in one position, the weight of the head resting wholly on the os occipitis. Its pulse was now uncountable; respiration more frequent than Dr. Sims had ever seen it before under any circumstances; it was breathing 120 times in a minute, and looked as if it could not possibly live an hour. He raised it up to examine the head more particularly and sat it on his knee, or rather leaned it against the knee, for the tonic rigidity of the muscles prevented the flexure of the thighs to a sufficient degree for the sitting posture. After holding it so for some ten or twelve minutes, a rapid amelioration of all its bad symptoms took place! The tonic rigidity remained the same, but the clonic spasms became less frequent and less intense; the whole expression was less disturbed and the respiration fell, in this short space of time, from 120 down to 70 in a minute. Dr. Sims now felt convinced that position had a great deal to do in the production of this disease.

On examining the head, he discovered that the fontanelles were open and very large, particularly the anterior, that the bones were loosely attached by their commissures, and that the os occipitis was pushed in on the brain, being overlapped for a quarter of an inch or more along the whole course of the lambdoidal suture, by the edges of the essa parietalia. He had the child laid on its side, so as to take the weight of the body from the os occipitis. It died about sundown, on Friday, 25 July, having been sick about 96 hours.

At the post mortem examination, the following appearances were observed.

No emaciation; countenance tranquil; slight cadaveric discoloration of back.

Head.—Anterior fontanelle large, triangular; coronal suture open in its full extent; sagittal same, open to ossa nasi; parietal bones overlap the frontal slightly; the occipital for the fourth of an inch along the whole of the lambdoidal commissure; gentle pressure on the occipital bone projects the brain forwards, producing a considerable fullness of the anterior fontanelle.

Brain.—Superficial vessels full of black blood, particularly posteriorly. Interior of the brain natural in appearance.

Spine.—Coagulum of blood occupying the spine in its whole length, enveloping perfectly the medulla spinalis; thicker as it approaches the brain. Spinal veins full of black blood.

Thoracic and abdominal viscera healthy; nothing unnatural about the appearance of the umbilicus.

Dr. Sims then proceeds to give a description of the anatomy of the parts with which of course we need not trouble our readers; after which he begins to explain his peculiar views on trismus nascentium which we shall lay before our readers fully. According to Dr. Sims then the head, by the labour, is elongated in the occipito-frontal diameter to its greatest possible extent, and it is consequently diminished in its vertical diameter to its smallest dimensions, by the parietal bones overlapping the occipital through almost the whole length of the lambdoidal suture. The edge of the occipital is always forced up under the edges of the parietal, at the posterior fontanelle, in every labour. There is not an exception to this rule. Now, as the parietal are compressed laterally, to diminish the biparietal diameter, they exercise a degree of traction over the "pars occipitalis" (independently of the forces acting on it from behind), drawing it upwards in a line towards the anterior fontanelle, and thus shortening the vertical diameter. After birth, the bones of the head gradually acquire their proper relative position: the head loses measurably its elongated shape; its vertical diameter increases; the occipital slides slowly from under the parietal; the frontal becomes more prominent; and the whole cranium assumes the normal oval appearance that of right belongs to extra-uterine life.

Now, suppose the fœtal cranium is not sufficiently well ossified to regain its proper shape by its own inherent elasticity; or, suppose the child is imprudently retained for a length of time in the recumbent posture on a hard mattress or a folded blanket with a little bit of hard old quilt, or a bunch of dirty clothes (as often found amongst negroes), wadded up and stuck under the occiput, what will be the consequence? Why, the occipital bone, instead of regaining its proper position, will be pushed further under the edges of the parietal; and the whole weight of the head resting on the occipital protuberance will thus force the *entire* "pars occipitalis" upwards. If this condition be persisted in, the whole cerebral mass will be displaced; the cerebellum will be compressed between the fossæ cerebelli and the tentorium; and it will thus be tilted forwards so as to produce great pressure on the whole tract of the medulla oblongata as it rests on the basilar process of the os occipitis. What is the result of this long-continued mechanical pressure, with its peculiar displacements? The circulation through the sinuses and veins of the brain is retarded; the compression of the cerebellum obstructs the cerebellar veins; the posterior edge of the foramen magnum becomes a constricting point on that portion of the medulli-spinal veins which empty their blood into the inferior cerebellar; the force communicated to the medulla oblongata powerfully obstructs that portion of the medulli-spinal veins which run forwards over the anterior or lateral edges of the foramen magnum to empty themselves into the petrosal sinuses; and thus the spinal venous circulation, as connected with the brain, is entirely cut off.

What is the consequence of this constriction, this ligaturing, as it were, of the medulli-spinal veins? Why, at first, there is a simple venous congestion within the dura mater of the cord, produced exactly in the same way that it is effected in the veins of the hand and forearm in the ordinary everyday operation of venesection. After a while the long tortuous network of thin delicate medulli-spinal veins is overcome by the persistent constriction above; the blood is extravasated within the dura mater of the cord, enveloping the medulla spinalis perfectly; and then we have the aggravated symptoms that always mark this infallibly fatal stage of the disease.

What is the reason that extravasation does not take place as soon as the constriction is made at the edges of the foramen magnum? Because the medulli-spinal veins communicate by transverse branches with the great spinal lying exterior to the dura mater, and thus the blood is carried into the general circulation by their anastomoses with the vertebral, intercostal, azygos, lumbar and sacral veins. But let the child remain long in this position and this collateral circulation becomes obstructed. By force of gravitation the spinal veins all become congested; there is no visa-tergo to drive the blood horizontally forwards, or, rather (as the child lies on its back), perpendicularly upwards; it almost ceases to flow; and the medulli-spinal ligated above and dammed up on all sides, having no outlet for the blood brought down by the anterior and posterior spinal arteries, must necessarily very soon yield and pour out their contents within the tube of the dura mater. Dr. Sims thinks it clear that the assemblage of symptoms constituting trismus nascentium is the result of pressure on the spinal cord exerted by venous congestion and extravasation; and equally clear that this effused blood is produced in the way that I have described.

Dr. Sims afterwards relates several cases illustrative of the probability of his theory.

England.

[The following are the only articles of interest to the profession in the last number of the Lancet.]

INTESTINAL HÆMORRHAGE.—DEATH.—Dr. Ormerod relates two fatal cases of intestinal hemorrhage which occurred in St. Bartholomew's hospital, under the care of Dr. Roupell. The first was that of a policeman, aged forty-four, a large, well-made man, married, and temperate, who was admitted on the 22nd of October, 1845, in the following state:—Flesh flabby; face dull; surface of the body quite blanched; tongue moist, with a thick brown fur on the dorsum, elsewhere pale and smooth; pulse 100, soft, thready, with a little thrill; bowels relaxed; profuse discharges of red coagulated blood from the bowels during the previous three months. He had been liable to attacks of giddiness; one severe attack three years ago he particularly remembered; but he was not aware that he had any discharge of blood from the bowels about such times. Three months before admission, he casually noticed, for the first time, that a large quantity of blood was mixed with his evacuations; he was not ill at the time, nor did he afterwards feel ill; since then he had vomited blood, from time to time, in small quantities, and had repeatedly passed large quantities from his bowels; he had gradually become so weak, that, eleven days

before admission, he laid up in bed from sheer exhaustion. After he laid up, a sore formed on the sacrum; he slept well; his appetite was moderately good; and, were it not for the colour of the evacuations, he would be quite unaware of any disorder of his alimentary canal. On auscultation, the heart's sounds were heard quite distinctly without any murmur; beneath the right clavicle there was some crepitation, with long expiration and pectoriloquy. He continued in the hospital during twelve days, getting gradually weaker, though he passed hardly any blood from his bowels during that period. He had not perfect control over his bladder or rectum; but as he appeared to suffer much when disturbed from the dull, sleepy state in which he always lay, no accurate examination was made of his condition, and he died on the twelfth day. The following appearances presented themselves at the post-mortem examination:—Limbs rigid; blood generally firmly coagulated in fibrinous and coloured clots. The coagula filled the cavities of the heart, and one extended into the aorta, whence a clot was withdrawn long enough to reach to the popliteal space. The veins also contained coagulated blood, and the clots in the auricles were plainly continuous with those in the ventricles. The heart was large, pale, and healthy in structure, but there were four pulmonary valves, one of them much smaller than the other three. The right pleura was universally firmly adherent; the left was free. Lungs generally slightly emphysematous, pale, remarkably destitute of blood in front; but here and there was a little congestion from gravitation, in which, on the left side, were some scattered granular masses of pale-grey tubercle. The same pale-grey tubercle was extensively deposited about the apices, especially the right, the tubercular matter was hardly distinguishable by colour from the rest of the pale-grey tissue of the lung. In the middle of the right apex was a single cavity, hardly so large as a hazel-nut, with smooth walls, lined by an opaque, soft, white membrane. The stomach and intestines, both small and large, were healthy, with the following exceptions:—Just beyond the pylorus was a large excavated ulcer, which had eaten through all the coats of the duodenum, and the base of which was formed by the apparently healthy pancreas, to which the edges were firmly attached. The ulcer might have been an inch and a half in diameter. The whole of the parts in the neighbourhood were coated with a thick layer of mucus; but there was no blood, nor any visible trace of vascular action, nor was it ascertained what artery had been laid open. The liver and spleen were, in all respects, quite natural. The kidneys were small, hard, pale, and tough, breaking with an irregular fracture. The capsule of the kidney was firmly adherent; the surface exhibited a few small cysts. On section, the cortical structure seemed rather deficient, and was marked with a scanty, buff-coloured deposit. The second case was that of a woman, aged twenty-four, delicately formed, admitted on the 24th of February, 1846. This patient appeared in the last degree of anemia. Face pale, quite bloodless, pulse rapid, like a thread; tongue moist and pale; gums crusted with blood, and spongy; numerous purpura spots on the chest. She lay on her right side, and was hardly able to whisper her complaints of intense pain in the head, and profuse bloody discharge from the bowels. She had always had good health, and since her marriage, twelve months before, had never had a day's illness till the present attack, which commenced gradually, with pain in the limbs, and weakness, and advanced so far as to lay her up a month before admission, suffering from pains and weakness, and passing blood from the rectum, which was said to be obstructed by hemorrhoids. She had had all the necessaries of life, and had never complained of anything beyond habitual constipation before this illness began. The blood mixed with the evacuations from the intestines was red, and partially coagulated. On auscultation, metallic clique was heard, loudest at the base of the heart, with the first sound; also a systolic murmur at apex and base, in the pulmonary artery and aorta; between the base and apex a double friction sound was distinctly audible, and there was an intensely loud murmur in the jugular veins. All the ordinary styptics having been tried without any effect, as they were constantly rejected by the stomach, the patient was ordered stimulants, wine, a blister to the region of the heart, and to take five grains of gallic acid every four hours. The next day her bowels were much less relaxed, the motions dark, with some fæcal matter. She had retained the medicine, and had no vomiting. Ordered to continue the treatment; to increase the quantity of wine from six ounces to ten ounces. On the 26th she was more lively, smiled, and expressed her feelings; she was perfectly free from headache; pulse 132, like a thread, tongue dry, rough, and brown, with some white papillæ; she had passed three liquid evacuations, with a sooty sediment. Her feet were a little œdematous, as they had been all along. Ordered to continue the same treatment. In the evening she asked for a cake, which she ate, and did not subsequently reject. She gradually changed during the night, passed three red, bloody evacuations; the next *morning* she lay on her right side, quite pale, with a rattling in her throat, and died about mid-day. On examination after death: The blood in the large veins was evidently quite watery; in the auricles the coagula looked like thin jelly. The lungs and pleura were considerably diseased. The heart presented spots of purpureous matter, its surface was dotted with bright red spots, and the serous membrane was puckered into wrinkles. The stomach was of the natural size, containing a good deal of closely adherent mucus, with dark shreds, as of altered blood. Through this coat of mucus could be seen numerous purpura spots in the mucous membrane of the stomach, with some distinct depressions, the result of follicular ulceration, chiefly occupying the great curvature, nearer the cardiac than the pyloric end of the organ. The duodenum was healthy; the jejunum and upper part of the ileum were marked here and there with dark stains, having a honeycomb appearance, probably disorganised Peyer's glands. The colour of these patches became more livid on descending the ileum. The situation of all of them was distinctly marked on the peritoneum by dark purple stains, dotted with little opaque, white spots, some of which also were scattered on the mucous surface of the lowest of the patches. The solitary glands were generally enlarged. The colon was ulcerated throughout; there were large patches where the mucous membrane had been removed from the walls of the intestine, and now hung down in brown sloughy strings, and hundreds of smaller ulcers, out of which small round sloughs were protruding. The large patches were chiefly in the ascending colon, the smaller round ulcers were pretty evenly distributed, only larger, and apparently of longer standing near the upper end of the colon. The upper part of the rectum was comparatively, but not absolutely, free from ulceration: this part of the intestine was rather contracted, but below where the canal was again distended the ulcers appeared as numerous, though not so large, as those above. All the ulcers had a thickened base, surrounded by an elevated ring of mucous membrane; in the more recent ones the mucous membrane could be turned aside, and a slough of cellular tissue removed with little difficulty, a little crack only remaining in the membrane, without any loss of substance; only in the more advanced had any of the lining of the intestine been destroyed. There were marks of vascular action round many of them, as well as round some of the hundreds of circular ulcers that existed above, as also some of the solitary glands, which were enlarged, but had not yet ulcerated, in the lower part. The mesenteric, and especially the lumbar glands, were large, soft, red, with white deposit; there was some sub-serous ecchymosis in the mesentery and omentum, and a little pure blood had gravitated into the pelvis. No blood was found anywhere in the intestines, only some bilious chyme in the upper, some dark fæcal matter in the lower part of the small intestines, and a small quantity of solid, dark fæces in the colon. The liver was large and flabby, the right lobe constituting almost the whole bulk of the organ. The upper surface was connected by tough, old adhesions to the under surface of the diaphragm, the under surface less firmly to the spleen. The spleen was large and hard, presenting two or three pale buff spots, one of them corresponding to a white patch on the capsule, while to another a flocculus of fresh fibrin hung. On section, the largest appeared about two-thirds of an inch in diameter; they were hard, yellow masses, surrounded by more or less vascular congestion. The kidneys were pale, having exactly the appearance of lumps of fat; their texture and structure under the *microscope* was quite healthy. The uterus was pale, small, and empty. The right ovary contained a cyst filled with dark fluid, and the left presented a corpus luteum. In this case the benefit derived from the internal exhibition of gallic acid was marked, for a short time, but the patient apparently was too much worn out by the disease to receive permanent benefit from any remedy.

NEUROMA.—The case of an ostler, aged forty-five, affected by neuroma of the posterior tibial nerve, treated in the Royal Free Hospital by Mr. Gay is reported. The patient was muscular, of middle stature, and was admitted on the fifth of September, 1845, complaining of dull gnawing pain along the course of the sciatic nerves, increased by pressure, occasionally shooting with great severity along the posterior tibial and the articular nerves of the knee, the peroneal, saphena, and other cutaneous nerves of the leg. Behind the trochanter, the pain was constant, but in other situations it was lancinating and irregularly paroxysmal; though most severe and frequent at night; foot benumbed; nights almost devoid of sleep; appetite gone; flesh and strength wasting; pulse feeble; and the patient unable to follow his usual occupation. The symptoms commenced about two years previously, with slight sciatic pains, which continued to increase and extend, until they became insufferably severe. On examining the course of the nerves, a tumour about the size of a large walnut was discovered above the tuberosity of the os calcis, and wedged in between the tendo-Achillis and the posterior aspect of the tibia; firm and inelastic; capable of being moved from side to side, but not upwards and downwards. Squeezing it gave severe pain, increased numbness of the foot, aggravation of the neuralgic pains, which he had so long endured, and arrested the circulation through the posterior tibial artery. These symptoms led to a strong suspicion that the tumour was connected with the posterior tibial nerve, and, from the evenness of surface, and regularity of shape, Mr. Gay thought it might be a cyst. Under this impression, Mr. Gay *recommended* that the contents of the cyst should be evacuated, and an attempt made to consolidate it by exciting suppurative inflammation of its parietes. A tolerably free incision was accordingly made, with great caution, into the tumour, parallel and close to the edge of the tendo-Achillis. This gave rise to profuse and bilious arterial hæmorrhage (only checked by powerful compresses above and below the wound) and increased numbness of the sole of the foot. An attempt was made to set up suppurative inflammation, but desisted from on account of the increased neuralgic pain it occasioned. No diminution in the size of the tumour followed these abortive attempts at treatment, but a small fungous growth sprung from it. Mr. Gay now determined on excising the tumour, which he did on the 11th of November. A free incision was made over the tumour parallel to, and about a quarter of an inch from, the inner edge of the tendo-Achillis, which laid it bare. From its lateral connexion, excepting the posterior tibial artery and veins, it was easily separated; and on proceeding to its superior and inferior attachments, it became immediately evident that the seat of the tumour was the nerve. The vessels were carefully looked for, and found imbedded in a groove on its posterior aspect, and firmly attached to it by cellular tissue. An attempt was made to separate the vessels, but

the difficulty appeared to be insurmountable, and it was decided to be less hazardous to put a ligature on the artery, both above and below the tumour, and to remove the included portion by means of a sharp and strong pair of scissors together with the diseased portion of the nerve About two inches and a half of the nerve, artery, and veins, were thus removed. Considerable hæmorrhage attended the operation; ligatures were applied to the bleeding vessels, and cold applications made to the wound; which, after half an hour, was closed by sutures. A distressing sense of numbness in the foot followed. The tumour was found to consist of, first, the ordinary neurilemma, and a layer of nervous fibrin, separated and regularly expanded over a thick, tough, and fibrous cyst, which was about the size of a walnut. This cyst contained minute cells, some filled with serous, others with bloody fluid. At the point where it had been punctured it had not healed, but the contained cellular growth had made its way through, and evidently formed the small fungous mass which had protruded. The patient suffered severely from pain and fever after the operation. After the healing of the wound, however, the sensibility in the sole of the foot gradually increased, and he had more power of moving his toes, though motion was principally confined to extension. He suffered severely from shooting pain in the course of the plantar nerves, and the remaining portion of the posterior tibial nerve, to the point of its division; but the sciatic and other pains which he had endured prior to the operation had quite left him. These pains commenced behind the inner malleolus, and lancinated along the plantar nerves. On the 1st of March, three months and a fortnight after the operation, the whole of the skin of the heel and sole of the foot was still benumbed, but he had more sensation in the toes, excepting the great toe; the shooting pains in the foot continued to return frequently during the night as well as day, and were brought on by using the foot in walking, but relieved by rest and rubbing in the tincture of aconite. The patient was unable to control and direct the movements of the foot with a precision sufficient to ensure an accurate fulfilment of the purposes of the will, unless the eye kept simultaneous watch over them. In ascending a flight of stairs he could not raise the leg to the exact height required for a single step, unless he kept his eye on the foot during the movement, and this assistance from his visual organs was required for each successive step. In standing no reliance could be placed on the defective foot. In walking great attention was required; and if, by accident, he set the foot on a small stone, or other body, which affected the evenness of surface, he lost his balance and fell.

Injections into the Uterus.—Mr. Tripe relates two cases showing the utility of injections into the uterus in certain conditions. The first case was one of passive hæmorrhage after labour, occurring on the twelfth day. The blood was red, containing small dark clots occasionally. The system was very much depressed; pulse 130, small, and jerking; face deadly pale; lips colourless; head hot; extremities cold, and skin clammy. The uterus was very high up; the fundus anteverted, in consequence of which the patient had difficulty, with frequent desire, of micturition. The os, looking almost directly backwards to the sacrum, was almost out of reach of the finger; but on hooking it downwards, it was found patulous, and nearly as large as a halfpenny. The finger passed into the uterine cavity, which appeared as large as a small egg, and was empty. No contraction occurred from the manipulation. A pint of cold water was injected into the vagina and womb. Ergot of rye and tincture of sesquichloride of iron were ordered every two hours, half a grain of oxide of silver, mixed with starch-powder, to be given during each interval, and a dose of black draught directly. The hemorrhage continued profusely, and the general symptoms increased in intensity. Four ounces of cold water, containing ten grains of tannic acid, were injected into the cavity of the womb, care being taken that but little force should be used, and that the tube should be carried within the os uteri some wine was also administered. After this the flooding ceased, and slight lumbar pains occurred. A clot was discharged of the size and shape of the cavity of the womb, with white fibrillæ attached to its surface. The patient recovered rapidl afterwards. In the second case injections of tannic acid were administered with much benefi in a case of profuse menorrhagia. Oxide of silver was at the same time administered internally and subsequently the sulphate of iron was taken.

Melanosis.—Mr. Holmes Coote reports two cases of melanosis (for which he is indebted to Mr Lawrence), and copies two cases from contemporary journals. The cases by Mr. Lawrence are of the ordinary kind, and neither in them nor in Mr. Coote's remarks on them, are there any points worthy of being transferred to our pages.

Placenta Prævia.—Mr Lloyd briefly record a case of Placenta presentation occurring in a twin pregnancy. Slight hemorrhage came on in the eighth month, and continued to a small exten for four or five days. A more severe discharge of blood then occurred, and Mr. Lloyd was sent for. During his visit a large gush took place, and the patient fainted. Mr. Lloyd therefore immediately proceeded to dilate the os uteri, passed his hand between the placenta and its attachments and, feeling a foot, ruptured the membranes. Slight pains came on and a small female child was delivered in a state of asphyxia. The usual means revived it however. On examining the patient another foot was found presenting, and a second female child was delivered also asphyxiated; this was also restored. The uterus was grasped by the nurse, and a firm bandage applied, the organ contracted and the placenta was expelled. The patient recovered, Mr. Lloyd states that he imagines the placenta in this case to have been attached, completely over the os uteri. This seems doubtful however. It was the patient's sixth pregnancy.

Neuralgia of the Uterus.—Mr. Davis mentions the case of a lady of full habit, aged twenty-five whom he attended in her confinement, and who progressed favourably towards recovery until the sixth day, when she complained of severe pain in the region of the uterus not aggravated by pressure. There was no fever nor any derangement of the circulating or digestive organs. Opiates and other sedatives were freely administered, both in a solid and liquid form, without benefit. The pain was intermittent in its attacks and during the intermissions, pain, was referred to the face, but not considered of much consequence by the patient. Various means were used to relieve the pain, and amongst other remedies calomel was administered, after which the pain in the face became more severe, and the patient, supposing it to arise from toothache, surrounded the parts with flannel. This circumstance led Mr. Davis examine the mouth, when he found the posterior part of the gum enlarged, red, and swollen. One of the dentes sapientiæ, was coming up; the gum was freely lanced, and the pain in the uterus from that moment subsided.

The Address to the Surgical Society of Ireland—by Mr. Carmichael, had been previously published in our number for May 23rd, 1846, page 160.

ORIGINAL LECTURES.

COURSE OF LECTURES ON PRACTICAL MIDWIFERY.

By EDWARD RIGBY, M.D.

Fellow of the Royal College of Physicians, Senior Physician to the General Lying-in Hospital, Lecturer on Midwifery at St. Bartholomew's Hospital, Examiner on Midwifery to the University of London, &c.

Delivered last session at St. Bartholomew's Hospital,' and revised by the Professor for the "Medical Times.

LACERATION OF THE PERINŒUM.

At our last meeting, gentlemen, I mentioned to you the fact that laceration of the perinœum, has been known to occur from the earliest periods, and that it is alluded to in the old Testament. I now have to inculcate the necessity of supporting this part, and to state to you the best means of doing so. I have before told you that towards the close of labour the perinœum becomes excessively distended by the pressure of the head against it, in fact in many cases it becomes so thin as to appear almost membranous, and to allow the inequalities of the child's head to be visible through it. To a person unacquainted with the dilatability of the parts, this immense distention would seem almost incredible, and this is the time when the danger of laceration may be said to commence. It is therefore well to be in readiness and to have a hand in the neighbourhood, when the head is distending the os externum for fear the head should suddenly burst into the world and thus rupture the perinœum. In primiparæ the frenulum perinœi is almost always lacerated, but this laceration ought not to extend further, which without great care it is very apt to do; in primiparæ therefore your utmost attention will be needed, both on this account and because the parts having never been distended before are not so dilatable as in females who have had many children. There are two periods when this laceration is most to be feared, one is when the head is passing into the world, the second and the most dangerous, during the passage of the shoulders. Often a slight rupture, as of the frenulum, during the passage of the head becomes a serious laceration during the delivery of the shoulders. Permitting the head to remain in the state of crowning during the interval of a pain assists greatly in dilating the parts, and preparing them for the passage of the shoulders.

The usual plan of supporting the perinœum recommended by writers on midwifery, is that by the right hand; I prefer using the left, gentlemen, because I have then the right hand free to perform any little manual operation about the child which may be necessary. You will find the position with the left hand rather tiring at first, but a little practice and dexterity will soon enable you to overcome this, and will make the use of the left hand quite easy. The use of the left hand is the plan generally employed by the Scotch practitioners. The best position for your patient during this period is that mentioned in my last lecture, I mean the usual one on the left side. Towards the middle of the fourth stage of labour when the pains are becoming pretty active and rapidly repeated it will be necessary for you to prepare for supporting the perinœum. You should apply a soft napkin to the perinœum and place your hand on this, both for the sake of cleanliness and to prevent the hand from slipping, and this napkin should be changed when wet. You will then place your hand with the palm towards the anus, and with the middle finger well over the centre of the perinœum. It is of considerable consequence to employ the pressure well and directly on the centre of perinœum. In order that you may be sure that you have your hand applied exactly in the centre of the perinœum you should place the examining finger of the right hand against the posterior margin of the os externum. If you apply the left hand so that the middle finger of it meets and touches the examining finger of the right, you may be sure your hand is in its proper position. Bear this in mind, gentlemen, bad support is worse than none at all. When the head is bulging out you may know by feeling the frenulum perinœi with your examining finger, whether the pain is likely to be the last or not.] If the frenulum be not tense you may be sure there will be more pains before the birth of the head. It is not necessary for you to keep up support of the perinœum during the whole of this period. Indeed you would find such a course exceedingly fatiguing. The plan I generally adopt is to keep my hand under the bed clothes, in readiness to make pressure the moment the head comes forward. The pressure should be applied with the palm of the hand directed backwards towards the anus and it should be made in a forward direction, as by this means we press forward the soft parts, and at the same time direct the head forward and against the other parts of the os externum, so as to ensure their bearing an equal share of the dilatation, and also thus avoid

the danger of the perinæum being perforated by the head. The fingers must be kept well together so that no space should be permitted between them.

Laceration of the perinæum may be a very serious injury, as it occasionally may extend backwards through the sphincter ani into the rectum. In such a case the probability will be that the patient will be rendered wretched for life. All the discharges of the uterus and rectum coming away in one vast cloaca, your patient, gentlemen, will be a misery to herself and to her friends. Fortunately, however, although considerable lacerations of the perinæum are not uncommon, they seldom extend through the sphincter ani; they usually take an oblique direction, and pass by the side of this muscle, and, of course, in these cases the rectum is rarely exposed to injury. Wounds in this situation are very disinclined to heal, partly on account of the difficulty of keeping the parts perfectly motionless, and partly on account of the irritation, caused by the discharges of the parts entering between the edges of the wound. Some practitioners have recommended that in the treatment of perineal laceration, the bowels should be rendered costive by a dose of opium, in order to prevent the wound being torn open by the passage of fœcal matter. In all cases, gentlemen, in which you may be so unfortunate as to meet with laceration of the perinæum, whatever may be the treatment you intend to pursue with regard to the permanent cure of the patient, let me advise you never to give a dose of opium to produce constipation of the bowels after her labour. Depend upon it, more harm than good comes of this measure; if the parts slightly or considerably unite, as by attention to rest and and cleanliness they often will do to a considerable extent, the passage of the hardened fæces after several days constipation will be sure to tear their edges asunder again, and you will then have your patient in a worse condition than before. Instead, therefore, of endeavouring to constipate the bowels, you should, on the contrary, render them as relaxed as possible.

My friend, Dr. Dieffenbach, of Berlin, has operated on many of these cases with great success. The following is the method he employs. Having pared the callous edges of the wound, he inserts very fine hairlip pins, with the twisted suture, bringing the parts accurately together; he then makes on each side of the laceration an incision through the skin and cellular tissue, which he dresses with charpie, so that the central wound is, as it were, completely isolated and removed from all danger of being disturbed by the patient's movements. The lateral incisions are allowed to heal by granulation. Dr. Dieffenbach, however, contents himself with attempting the union of the posterior two thirds of the wound only. I believe, gentlemen, the great fault in the treatment of perineal lacerations, is, that we attempt too much; by endeavouring to obtain union of the whole surface, the tension of the parts is greatly increased, so that the chance of union is much lessened; besides which, if you should obtain union of the part, the perinæum will be so contracted, that should the patient again become pregnant, laceration will be sure to occur during her labour.

Some writers have stated that support of the perinæum, during labour, is quite unnecessary. One of the arguments advanced by authors supporting this view is, that among savage nations it is never employed; but these gentlemen have entirely omitted to take the smaller size of the head among savage tribes, into the account. Besides this, women among savages, generally speaking, are more inured to hardship, and are ...y stronger, and bear pain better. Cases may occur, certainly, in which support of the perinæum may not be required, and on the other side of the question, cases do occur continually in which, in spite of all the care of the medical attendant, laceration cannot be prevented. Some surgeons have stated that they have never had a case of perineal laceration. Such gentlemen cannot have enjoyed a very extensive midwifery practice. One thing seems to deceive practitioners; that is, that the parts contract very much and a rent which, at the time of its occurrence when the parts were distended, appeared enormous, would, in the course of day or two, be scarcely worth speaking of.

When the head comes down very suddenly and the os externum is rigid, the perinæum may give way in the centre only, if assistance be not at hand; this, gentlemen, is called *central laceration of the perinæum.* The child in these cases is born through the aperture, and the frenulum perinæi is left uninjured. This chiefly happens in cases in which the part is unusually broad. I have witnessed two cases of this accident, and in neither one was the rectum injured. In these cases I merely ordered the patient to be kept quiet, and the parts to be kept very clean for 48 hours, and I found the rent contracted considerably. In about six days the opening remaining was barely sufficient to admit a catheter. This also healed eventually, and I afterwards attended the patient in a subsequent pregnancy, when she was delivered *per vias naturales* without injury of the parts.

When the head is delivered, you must by no means remove the support until the shoulders have been born, for as I before told you, laceration of the perinæum is very apt to occur during the birth of the shoulders. In fact most of the worst cases of laceration are produced by the passage of the shoulders, the frenulum having given way during the birth of the head; when once a small rent has been formed, the laceration spreads very rapidly. You must therefore not remove the support, and its continuance will also be of service in preventing the uterus from being too suddenly emptied of its contents, which rapid emptying is a very frequent cause of hæmorrhage. You should never in these cases seek to expedite the delivery by manual assistance but rather to retard it.

After the head is born, before the birth of the shoulders, you should examine whether the cord be round the neck or not; and this of course you will do with your right hand, if as I advise you, you support the perinæum with the left. If you should find the cord round the neck, gentlemen, what are you to do? authors recommend that it should be passed over the head of the child; but I can tell you, gentlemen, that if it be loose enough to be passed over the child's head you need not meddle with it at all.

You must endeavour to slip the cord over the foremost shoulder, and it will soon of its own accord slip over the other shoulder. All this you will find you can do much better with the right hand than with the left. You may sometimes have the cord tightly twisted round the child's neck and cutting deeply into its soft folds. Now what are you to do in such a case as this? It is very evident now, that you cannot pass the cord over the child's shoulder, still less over its head. It has been recommended to tie the cord in two places and divide it, but, gentlemen, you will not be able to do this. I advise in such a case as this, that the cord should be divided at once; the child will be immediately expelled, when you must instantly secure the cord. These cases, however, are very rare, for there are few where with a little care we cannot slip it over the shoulder. This subject, however, I shall speak of more fully when we come to the consideration of dystocia.

When the child is expelled in ordinary cases you need not be in a hurry to divide the cord at once; rather place the child in a comfortable position by the side of its mother, where it can enjoy the warmth of her body, and wipe out its mouth with a soft napkin. As soon as the child has cried stoutly, the respiration is pretty well established, and the pulsations in the cord have ceased, you may tie the cord. I have made many observations as to the time that elapses before this occurs, and I think that the average time before the action of the child's heart is fully established, is about six minutes. Bear this in mind: you should never tie the cord before the circulation of the infant is fully established.

The mode of tying the cord is in my opinion of some importance. It should be tied as tightly as possible at about two inches from the umbilicus, and a full inch should be left beyond the ligature, because when the cord shrinks the ligature is very apt to slip off. Some practitioners put on two ligatures before cutting the cord and then divide it between them; I do not see any necessity for this, as, even in twins, the circulation is, as I told you on a former occasion, perfectly distinct. I think the loss of the few drachms of blood contained in the placenta, rather advantageous as it lessens its size, and permits it to be more easily expelled. The same rule of following nature which induced some practitioners to imagine that the perinæum did not require support made others suppose that the cord did not require tying. The contusion of the cord from the mode of cutting it, or rather bruising it asunder among savage nations, and the laceration of it by animals in their mode of separating the placenta by biting the cord in two, prevents hemorrhage in these cases. Analogy would therefore lead us always to cut the cord with blunt scissors. Dr. Gooch told me that he once unintentionally cut the cord on the wrong side of the ligature, but in this case the child's life was saved merely from blunt scissors having been used. On the continent some time ago, it became a fashion with some practitioners not to tie the cord at all; but this practice was soon put a stop to, by the occurrence of several severe cases of hæmorrhage. On the mode of dividing the umbilical cord among animals, I will read you the following extract from Dr. William Hunter's lectures in manuscript, as quoted by Dr. Merriman in his synopsis of practical midwifery—a work by the way, gentlemen, which I strongly recommend to your attentive perusal:—it is very short, but at the same time very valuable. Dr. Hunter says "a ligature upon the navel string is absolutely necessary, otherwise the child will bleed to death; and when tied slovenly or not properly, it will sometimes bleed to an alarming extent. As we take such vast care to secure the navel string, you will naturally ask how brutes manage in this particular? I will give you an idea of their method of procedure, by describing what I saw in a little bitch of Dr. Douglas's: the pains coming on the membranes protruded, in a pain or two more they burst and the puppy followed. You cannot imagine with what eagerness the mother lapped up the waters, and then taking hold of the membranes with her teeth, drew out the secundines; these she devoured, also licking the little puppy as dry as she could. As soon as she had done I took it up and saw the navel string much lacerated and bruised. However a second labour coming on, I watched more narrowly, and as soon as the little creature was come into the world, I cut the navel string, and the arteries immediately spouted out profusely; fearing the poor thing would die, I held it to its mother who drawing it several times through her mouth, bruised and lacerated it, after which it bled no more." This shows, gentlemen, that if the cord be bruised and lacerated there will be no fear of hæmorrhage.

As soon as the child is removed, one of your most important duties comes on, you must place your hand on the abdomen to discover whether the uterus, which now contains only the placenta and membranes, be properly contracted. This is a matter of the utmost importance, as until the fundus of the uterus has firmly contracted, the patient is not safe from hæmorrhage for a moment. Although no blood may escape externally, still the patient may be dying of internal hæmorrhage. In these cases the fundus of the uterus becomes soft and irregular, and the os uteri may have become contracted either in consequence of irritation to it from pulling the cord, or from being plugged up by the placenta or a coagulum of blood. It is therefore of the very utmost importance to examine every few moments to ascertain whether the uterus be firmly contracted or not. If the organ be firmly contracted after the expulsion of the child before the removal of the placenta, it will be about the size of a child's head, when felt through the abdominal parietes. After the expulsion of the placenta

the organ contracts yet more firmly, and becomes about the size of a cricket ball. It may be felt just above the pubes in that state. But, gentlemen that our time is expired: I must therefore postpone the further consideration of this subject to our next meeting.

A COURSE OF LECTURES ON DISEASES OF THE SKIN

By JAMES STARTIN, Esq., Surgeon to the London Cutaneous Institution.

LECTURE XVIII.

SYCOSIS

GENUS	SPECIES
Sycosis.	Menti Capillitii

As proposed by Startin

GENERA AND SPECIES

Sycosis.		
S. Simplex vel Tuberculata	Menti	Sparsa
S. Pustulosa	Capillitii	Confluenta
S. Crustata		Inveterata
S. Ulcerata		

Gentlemen, our meeting last week, was devoted to the treatment of a cutaneous disfigurement chiefly of the face called acne, for the most part more prejudicial to the beauty, than to the health of the individual. I am now about to direct your observation to a very similar disease which affects the same part of the body, I may say, exclusively, its site being in the sebaceous follicles of the face and head, which are permeated by the hair of the beard, whiskers, eyebrows, or scalp, and which is also, unattended with any necessary derangement of the general health.

This disease has been known to ancient and modern writers on medical subjects by the distinctive appellation of sycosis, and was alluded to by Pliny, as a malignant affection under the name of Mentagra, which term is continued by most continental authors on cutaneous diseases, since the days of Plenck as however the whiskers, eyebrows, and scalp are attacked by this malady as well as the beard, I shall prefer using the term sycosis rather than a designation which would seem to confine the complaint to the chin.

Sycosis strictly means figlike, and has probably been applied to the affection under our notice, from some real or supposed resemblance its originator may have discovered to the fruit in question. But you have only to refer to your anatomical nomenclature, to perceive how common and fashionable, this mode of designation was in bygone periods of medical history, and on what slender marks of resemblance, it was usually founded. I show you a cut fig, and a model of the disease, so that your judgment may be settled on this point at least, by the fruits of observation, the resemblance you will observe, if any be existing, must depend upon the presence of numerous small yellow pustules, which, as it were, exude a greenish yellow ground of concreted secretion; which secretion, is the product of the rupture and discharge, of former pustules. Sycosis has been considered by most writers of authority as a pustular disease, yet were it to be so considered, it would not be distinguishable from impetigo, or porrigo affecting the same part of the body. I am therefore inclined with Bateman, to regard tubercles, as in acne, to be its more characteristic signs; and would consequently define sycosis as a non-contagious eruption of inflamed red tubercles or vari, resembling those of acne occurring on such part of the face and head as are covered by hair, (the precise seat of the disease being the sebaceous follicles permeated by the hairs). These tubercular spots, may vary from the size of a grain of mustard seed to that of a pea, and may be confined to one portion of the beard, whiskers, eyebrows, or scalp, or be disseminated very generally through these parts: wherever situated, they speedily suppurate and produce a small yellow pustule which is usually transfixed by a hair passing through its centre. These pustules break, coalesce and discharge a sanious yellow secretion, which attaches itself to the hairs so as to form greenish or sienna coloured crusts; beneath which, in inveterate varieties of the disease, ulcerations are occasionally found; and it is observable in nearly every example of sycosis, that tubercles, pustules surrounding the hairs, and incrustations, are to be simultaneously witnessed.

When the hairs plucked from a pustule of sycosis, are examined by the microscope, the extremity which was inserted into the skin, is found covered with a pulpy matter extending over the whole portion which was beneath the cuticle. I have not, however, so completely investigated this appearance microscopically, as was my intention before offering you these remarks, I trust, notwithstanding, to find leisure to do so shortly, and will then furnish you with the results.

It will be perceived from this definition, that acne differs from sycosis only in the implication of the hair follicle and bulb in the latter disease. The period of life is also similar to that in which acne, in forms of rosacea, and indurata, is commonly observed; namely, from twenty-five to fifty-five years of age. The subjects attacked are also similar, no condition being exempt, and irregular livers or intemperate persons being commonly its victims. In females, the disease is only witnessed on the eyebrows and scalp. When existing on the chin and cheeks, if this ever be the case, it is not distinguishable from acne rosacea, by any characteristics with which I am acquainted. By a reference to the chart you will perceive, I have divided sycosis into four species, which indeed are but so many stages in the complaint; yet, as in other instances of cutaneous disorders, I have thought it well to institute this sub division, that the exact period and aspect of the disease might be characterised, whilst the memory might be stored with its ordinary manifestations. Thus I have [illegible] genera of [illegible] as, as S. simplex, which comprehends the tubercular erythematous condition of the eruption; S. Pustulosa, when pustules are most evident, crustata, when scabs or crusts are most conspicuous, and ulcerata for the rarer instances, where ulcerations may present themselves. The divisions are according to the position of the disease on the beard, or other parts of the head, named after Bateman and others, menti, and capillitii: whilst the varieties relating to the form or continuance of the complaint, are entitled, Sparsa, Confluenta, and Inveterata.

According to my own experience, sycosis commences, three times out of five, on the upper lip immediately beneath the nostrils, by a raised tubercular erythematous swelling, which is attended with pain, heat and pruritus, and soon becomes covered with red elevated points that end in small yellow pustules which have a hair in their centre. The friction to which the patient usually subjects the part, and the effects of the heated and perhaps acrid breath, constantly passing over them, soon produce an extension of the eruption to other parts of the beard. The skin meanwhile assumes a deep red or violet tint, which is much increased by the use of soap and the razor, and the pustules multiply, till the whole hairy parts of the face and more or less of the scalp may become affected. In other instances this disease appears to commence in a similar manner to the above on some other part of the face, or it may, like acne, appear simultaneously on all the situations occupied by the hairs; while true acne exists on the cheeks, nose, and forehead, as the sycosis advances, considerable thickening and induration of the cellular tissue, beneath the skin take place, whilst the skin itself is much hypertrophied so as to present the lobulated appearance also observed in acne Rosacea.

Modifications of this complaint from a syphilitic taint, or scrofulous diathesis are of frequent occurrence, and will be hereafter separately mentioned.

Sycosis has been considered; even in modern times, a contagious disease, but this I have no doubt has arisen from its accidental complication with some other contagious cutaneous affection, as scabies or porrigo; with the latter of which complaints it is also not unfrequently confounded but the presence of tubercles, as in the models before you, and the origin and progress of the disease, will commonly furnish a sufficiently correct diagnosis. I am not aware that seasons, have much influence in the production or development of sycosis; the malady is very prone to remissions and exacerbations and the periods of the year which witness such occurrences, vary in different individuals afflicted with the disease. Tubercular syphilitic eruptions, and the disease called Ecthyma which we are about to consider, have some faint resemblance to sycosis, when they attack the face, but the seat of these affections is not in the hair follicles, nor does the root of the hair usually manifest the same morbid changes when it may happen to be implicated besides those eruptions are rarely, if ever, confined to the only sites occupied by sycosis, but are to be found in various other parts of the body never infested with the complaint under consideration. The causes producing sycosis are even more obscure than those enumerated as influencing the eruption of acne, yet in some instances they are undoubtedly the same, and may be distinctly traced to disorders of the digestive or chylopoietic viscera. The complaint is frequently very rebellious, and has been considered by nearly all dermatologists to resist every kind of treatment, sometimes ceasing spontaneously after a few months' duration, but more commonly having a protracted existence for years, which, in a great measure, as observed by Plumbe, is owing to the local irritation of the hair, acting like a foreign body in the pustules, and continuing and propagating the morbid inflammatory action constituting the disease. You will perceive, from what I have now said, that I agree with the author just mentioned, in his observation "that the existence of hair on the part, and consequence in aggravating the inflammation, form the only difference between sycosis and acne." (*Plumbe Practical Treatise on Diseases of the Skin. P. 59 et seq.*) With this view of the disease, I can have only one addition to make to the treatment I last week recommended for acne, particularly for the species known under the designation of A. Rosacea; and this is, that as the hairs constitute the only distinction between one affection and the other, it becomes a rule, as conclusive as it is practically useful, that they should be extracted by a forceps from all the inflamed vari as fast as they appear, and thus the maladies will be rendered identical, and require only a similar treatment. As this operation is not only tedious, but painful, requiring also daily attention, it can scarcely be accomplished at once, when the disease is extensive, or when, as is often the case, it is accompanied with much incrustation and matting of the beard: it is better, in these instances, to wash and bathe the parts freely with yolk of egg and tepid water, and to use the convex-bladed scissors to short n the beard or hair, and remove it with the adherent incrustations, when a small portion can be daily placed under the operation of the forceps, until every hair growing upon the inflamed portion of integument is scrupulously eradicated. Fomentations of decoction of mallows or poppies, of linseed, or of warm water, in which a little sulphur and bran have been boiled (in an earthen vessel), are very serviceable, both before and after this operation, and I would recommend the sulphur-vapour douche as a most valuable accessory.

This bath can be readily applied by means of any contrivance, at the end of the steam-pipe, which will exclude the nose, or, as is the preferable mode, the whole face may be subjected to the sulphurous vapour, if the nose be provided with a tube for inspiration. With regard to the prognosis of this troublesome, painful, and disfiguring complaint, I must again venture to place my own experience, and the results attending the practice at this institution, at variance with the observations of the authors, who have ranked acne and sycosis as amongst the most obstinate or incurable of diseases of the skin. By paying attention to the extraction of the hairs, to the use of the scissors

instead of the razor, and to washing and anointing the parts, after the manner recommended for acne in my last lecture (the use of the lancet: cauterization being also occasionally required) and the internal treatment directed as then advised I have often succeeded in curing sycosis of twenty or thirty years' duration, in as many weeks. If the cure has not been perfect, in all instances and if relapses have occurred from time to time as in acne, yet do I believe that this disease much more under the control of the medical art than many others which have no corresponding character for obstinacy and duration. As usual I shall verify these remarks, and conclude the subject by the citation of two or three cases which have furnished the modeller with the examples before you.

The first model of sycosis to which I shall bring your notice is numbered 6043; it is that of George Richardson, aged 38, residing in Cotten's yard, Hackney Road. He was admitted patient on the 29th of August, 1845, having suffered upwards of two years from his disease, which is very fairly represented by the cast you are inspecting. You will perceive that nearly the whole surface covered by the beard and whiskers is implicated in this loathsome looking malady; and, if I remember rightly, the eyebrows were also affected though the modeller has confined his attention only to the chin and parts adjacent. You will perceive on the boundaries of the greenish yellow incrustation, that tubercles are visible in several points, which in this individual contained pus surrounding some of the hair follicles; in other portions of the diseased parts, pustules are visible, which are transfixed by one or more hairs whilst much hypertrophy of the integuments is every where existing, where the complaint has extended, the whole forming together a frightful mass, which obliged its unfortunate possessor to seek relief from many sources; several hospitals had been tried in vain. There was great heat and tension of the parts affected, the breath was offensive, the tongue white, the digestive functions deranged, and the bowels costive. He could give no reason for the origin of the disease, which commenced by a swelling beneath the nose, which was hot and painful, and after a short time became covered with small yellow pimples full of matter, which broke and adhered to the beard and formed the crusts you witnessed in the model; in a month or two, the whole hairy part of the face became affected, and the malady increased under whatever treatment was adopted, until his presentation here, when the model was taken, and a very frightful looking affair it is, yet not so much so as the reality. After this patient left the modeller's hands, the parts were steamed with the vapour of boiling water, to soften the crusts, and then washed with the yolk of an egg and tepid water, until the curved scissors could be used, so as to see what we were about. Several small ulcers, with fungoid looking granulations were thus discovered, and a crop of pustules exposed, transfixed by the hairs in the manner I have described; the forceps were used freely and a mildly stimulating ointment afterwards applied, composed as follows,—white precipitate of mercury gr. xv., strong mercurial oint. ʒj. Liquor of acetate of Lead ʒss., Recent, pure Palm oil ʒvj. This made a smooth cream-like application which suited the parts very well. To combat the general disorder, brisk acidulated saline purgatives were administered, which, when the desired effect was produced, were combined with a chalybeate, and he attended at the end of the first week so much ameliorated in every way, that he could scarcely believe in his good fortune. Of course the same means were continued, daily ablutions with the yolk of an egg and water, the daily use of the scissors and of the forceps being persisted in, and so he went on, until the end of September, scarcely a month from his first attendance, when I had the satisfaction of writing *cured* against his name, and I sent for him here to-day that his presence might verify what I have told you concerning him.

The next case I shall relate, is that of James Beasley aged 82, residing at Sidney Green, Islington, admitted 12 days ago, the model of whose disease is numbered from its place in the register, 6868. I introduced this patient to you last week, when had been few days only under treatment, and even then some improvement had taken place in his malady, which I believe was visible on comparing it with the cast taken on his admission. I bring him forward again to day, so that his continued and satisfactory improvement may be witnessed. This individual has suffered more or less for seven years, and having been informed by the druggists he consulted, that his complaint was incurable, consequently he had never sought regular medical aid, before his present application. I shall not describe the condition of this patient at length, as you have just had the opportunity of witnessing it, and it is represented on the cast suffice it therefore to say, that his disease did not differ materially from that of G. Richardson just mentioned, yet the complaint was less violent and extensive, though of much longer continuance, a fact evident enough, on comparison of the two models. An acidulated chalybeate was administered in a vegetable bitter to this patient, and he was purged with a daily dose of sulphate of magnesia; the external treatment was precisely the same as that already detailed in the former case, save that the black sulphuret of mercury was substituted for the white precipitate in the ointment, and from the marked improvement manifest, I think you will agree with me, he should continue the same plan of treatment, and to attend once a week. I will take a future occasion to let you observe his progress. I have now to beg your attention to an example of this disease, which I consider by far the most remarkable case of Sycosis which I have been so fortunate as to conduct to a favourable termination. It is that of *Gavin* [illegible]*t*, aged 45, a native of north Britain, who was admitted about two years ago, having suffered more than twenty years from inveterate Sycosis, which had resisted the efforts of the medical and surgical officers of most of the best hospitals in Edinburgh and London, which, as this individual had been well educated, he had sought, as probable sources for relief, selecting those only which had a kind of special reputation in these matters; had besides read and thought much on his disease, which had kept him in a degraded position, during so many years of his life, and occasioned his being shunned, and as it were banished from all society. In this severe case the Sycosis had extended to the forehead, and all the hairy parts of the face, and so much hypertrophy existed in many of the diseased parts, that the disfigurement was hideously great: the upper lip was quite lobulated, and a stiff yellow beard grew out of the surface covered with fungoid-looking granulations that oozed, a muco-purulent secretion. I had more leisure at that period than now falls to my share, and I spent many hours at different times in removing the hairs from this diseased mass, and in opening the tubercles when suppuration could be detected, anointing him with my own hands; in short, in carrying out the principles I have detailed. He took iron in various forms, but received the most marked benefit from the iodide internally administered, and iodide of sulphur externally, in the form of ointment (15 grains to the ounce of lard,) by which conjoined means in two or three months he was perfectly freed from his disease, save that a few of the eye-lashes seemed to have been permanently destroyed. This individual attended unasked and unexpected one of the early public meetings of the Committee of this Institution, and by a forcible, clearly expressed and acutely felt, detail of what he had suffered, and the benefit derived, contributed, perhaps more than any other single case, to fix an assurance of the usefulness of this undertaking in the minds of its earlier supporters. I have seen Scott on two or three occasions since he was well, in consequence of a slight reappearance, as he thought, of the Sycosis; but the extraction of a hair or two, and a return to his medicine and applications for a week or so, have always been sufficient to remove any inconvenience from which he may have suffered; and for the past eighteen months I have lost sight of him, so that I feel assured he has experienced no return of his twenty years malady. At the same time, let me repeat a caution, which cannot be expressed too often on my part, or recollected too tenaciously both, by patients suffering under cutaneous diseases, and by those who undertake the treatment of these troublesome maladies:—this is, that they are very liable to return, unless the greatest care and watchfulness be exercised by all parties concerned.

The few minutes that remain of the allotted time of our meeting may I think, be more profitably employed for those gentlemen, present, by inspecting the morbid appearances manifested by the hairs plucked from the vari of Sycosis, as displayed beneath the microscope by Mr. Topping; a more minute examination of the two patients in attendance, who are recovering from this loathsome disease, may also be gratifying. I shall, therefore conclude to-day, by announcing that the next lecture will be devoted to the united subject of rupia and ecthyma.

THE NATURE, CAUSES, AND TREATMENT OF MENTAL DISEASES.

By M. PINEL, M.D., Member of the Academy of Medicine, formerly Physician to the Bicêtre and Salpetrière Asylums, Author of the "Traité Medico-Philosophique sur l'Aliénation Mentale," "Medicine Clinique," "Nosographie Philosophique," &c., &c. Translated, with Notes, illustrative of some important Doctrines in Physiology, Phrenology, and Moral Education

By Dr. COSTELLO,

Principal of Wyke House Asylum, Editor of the Cyclopedia of Practical Surgery, &c.

CEREBRAL CONGESTION.

M. Andral thinks, as regards the entire encephalic system, that the grey substance is the chief seat of sanguineous congestions, and he admits that they occur under five different forms. In those of the first form the symptoms are slight; the great cerebral functions, intellect, sensibility, and mobility are undisturbed; but we have headache, vertigo, stupor, somnolency, sluggishness of the movements, or a vehement desire to be moving and active. This form of cerebral congestion gives rise to convulsive motions in the limbs. The pulse is full, tense, hard, and vibrating; the temporal arteries beat strongly, the face is flushed, and the heart palpitates, with suffocation, and swelling of the superficial veins. These symptoms may last but a short time, or be prolonged; they may recur from day to day, or at much more distant intervals, or they may terminate in cerebral hæmorrhage, or in some other serious affection of the brain.

In the second form, there is sudden and complete loss of consciousness: the patient falls heavily, the limbs are relaxed or stiff: this is the apoplectic congestion. The insane attacked with general paralysis, almost all die from this form of apoplexy. In the majority of cases this congestion is not fatal; the health is restored gradually, the intellect remaining feeble, the senses weakened, and the pronunciation embarrassed for some time. This general congestion, which when violent, possesses all the characters of cerebral hæmorrhage, is only distinguishable from it some time after the fit, by its being followed by a speedy termination.

The third form is characterized by hemiplegia; and what distinguishes this form of hemiplegia from that which results from cerebral hæmorrhage is, that it may disappear suddenly. But the hemiplegia may persist, although there be no cerebral hæmorrhage: the tongue may become paralysed suddenly, and convulsions often occur in this third form.

In the fourth form, lesions of the sensibility and mobility predominate, either separately or combined. A patient had several attacks of general paralysis every day for a month, lasting five or six minutes; he was cured by abundant blood-letting. A child, four years old, was subject from its infancy to momentary attacks of paralysis; if the attack came on while the child was standing, the lower extremities suddenly

bent, and he fell to the ground; if in bed, the whole of the muscles became relaxed, the sensibility blunted, and speech impossible. He died of another disease. The superior longitudinal sinus was found obliterated.

In the fifth form, the disturbance of the intellect is the most prominent symptom; then delirium is intense, the muscular powers acquire enormous energy, the congestion extends to the origin of the respiratory nerves, and the patient dies as it were from asphyxia, with a livid and purple aspect.

M. Andral, having described cerebral congestion under these forms, asks how it is that a disease whose anatomical characters are the same, should give rise to symptoms so different and so various. He thinks justly that this difference depends on the difference of the seat of the disease, although it is obvious that we are not able to fix from what part of the brain such symptoms arise. I believe, however, that some of the ideas already enounced may now contribute to a more easy solution of the question.

We have yet to determine the exact relations of the motory and sensitive fasciculi with each other, their limits of demarcation, connexion, and especially the relations between their nervous extremities, and the peripheric cortical substance. Explanations will then be more easy, and already it is something to know what we have to look for, and to be able to foresee a possible solution in questions of so much difficulty.

Sanguineous congestion, is clearly a primary condition in all cerebral affections: if it persist, it readily degenerates into irritation, or even into inflammation, and these two causes of disorganization give rise, either slowly or rapidly, to the most profound alterations of the cerebral pulp. We have already seen that simple congestion, produces the most marked disturbance of the sensibility and motility; in its fifth form we have furious delirium, and a high degree of nervous cerebritis, which in this case is nothing else than a diffuse hæmorrhage throughout the capillaries, and which produces death, by asphyxia, before it has time to become developed. Now whether it be on a large, or a small scale, we shall always meet with the same elements, and the same symptoms in almost all the affections of the encephalon.

II.

CEREBRAL INFLAMMATION.

Inflammation of the brain, may be confined to a hemisphere, or a portion of one, or of the gray or white substance; or it may, like congestion, occur in the different parts of the encephalon, in a nervous centre, or in a few convolutions only.

Wherever it may be seated, its anatomical characters are always the same; it begins by congestion, followed by slight tumefaction, with redness of the inflamed parts. The first effect of this inflammatory injection, is to augment the consistence of the nervous tissue, whether cortical or medullary, and then to cause a ramollissement; but in such a case the ramollissement, is always accompanied with some degree of injection, from which it has been named, ramollissement.

After the inflammation has lasted a sufficient time, traces of suppuration may be found, and this is always a sure sign of inflammation, excepting in a case of phlebitis where the pus usually occurs in the state of infiltration. The membranes almost always participate in the peripheric inflammation of the brain, it may even commence in the membranes, and the reciprocity is attested by the frequent sanguineous and serous congestions of the piamater and arachnoid.

Certain chronic affections of the brain may become a centre, around which inflammation of the nervous tissue may be developed. Thus we find encephalitis following the formation of a cyst after cerebral hæmorrhage. It has been observed that a large number of scrofulous children die of inflammation of the brain; this is now known to be the consequence of tubercles in the brain around which inflammation takes place.

Andral moreover considers the symptoms of cerebral inflammation in reference to disturbance of the intellect, to be a variable delirium in its form and intensity—this delirium may be furious, loquacious, or taciturn, it may be complicated with disorder of sensation, or motion; it varies in duration, and may be followed by a state of coma terminating in death. In other cases, the patient dies during the furious delirium The delirium and coma often alternate with each other. Have we not here the symptoms of furious mania? And what then is maniacal furor, but acute cerebritis at its commencement? In some cases the delirium is shown o[illegible] in the beginning, in others it com[illegible]on later. It may continue after the inflamm[illegible]on, and it is not rare to find *mental alienation* succeeding encephalitis, or terminating in enfeeblement of the intellect, or of one of its faculties, the memory for instance; and the acute cerebritis passing into a state of indolence and chronicity and giving rise to symptoms on which we bestow the name of chronic mania or demency. On this point, the name is of no importance, but the physical cause in our estimation is every thing.

The lesions of motion and sensation are no less remarkable in acute cerebritis than are violent agitation, subsultus of the tendons, convulsions, contraction, and paralysis. The convulsions affect only certain muscles of the eyes the tongue and limbs: the paralysis extends successively to the face, tongue, limbs, to the muscles of the pharynx, larynx, bladder and rectum; it is usually preceded by convulsions and contractions which may alternate, or succeed each other in the limbs.

As to the lesions of sensibility, they are shewn in cephalalgia, illusions of the senses, and general or partial exaltation; sometimes by abolition general or partial, or by an exquisite sensitiveness of [illegible]t or hearing.

If i[illegible] beginning, or almost throughout the entire progress of mental alienations, we observe any other than these symptoms, we shall be forced to admit that their organic causes must be different; but as this sketch corresponds closely with its principal phenomena, we must not hesitate to acknowledge it, and to seek by deep study of their physical causes, correct notions on the seat and nature of the disease.

III.

CEREBRAL RAMOLLISSEMENT.

Softening is characterized in the dead body by a softish, pulpy, state of the nervous substance; sometimes instead of the nervous substance, we find only a liquid matter in which shreds of white and grey matter held in cellulo-vascular tissue, are floating. In other cases of softening, the grey substance both peripheric and central is often discoloured. The local and partial ramollissement is the most common; it has been found chiefly in the convolutions, optic tracts, corpora striata, cornua ammonis, corpora callosa, septum lucidum, or disseminated in several points.

Lesions of the intellect coincide mostly with softening of the cortical substance of the convolutions. Rostan who was the first to notice this pathological decomposition, has observed the intellectual powers equally disturbed in a case where the softening occurred at the base of the posterior lobe of the brain.

Softening has been found at all periods of life, in infancy, and in adult and old age; it shews itself frequently in autumn in the infirmaries of the salpetriere. In its progress, as well as in its anatomical characters, it exhibits the effects and traces of the general debility of old age, and here it is more a senile decomposition than a result of inflammation; and this is the character amongst those old people, of almost every inflammation; in them pneumonia is latent, without cough, pain, or sputa, erysipelas of the skin indolent, and requiring stimulants to make it progress. The cerebral softening is in the same condition; it is asthenic and has not strength enough to be inflammatory.

Paralysis is one of its most constant effects; it comes on gradually or suddenly; it begins by prickings, and odd sensations in the fingers and arms, and then assumes the character of a sudden apoplectic seizure. When the patient is first seen in this state, the diagnosis is uncertain; we have to wait a day or two, in order to ascertain, whether the case is one of cerebral hemorrhage, or softening. In hemorrhage, unless the outburst be very great, there is always some slight amendment next day; but in the softening which first shews itself in this manner, the symptoms become more and more aggravated, and the symptoms affecting motion and sensation are those which demand our most attentive examination.

The lesions of sensibility are marked by fixed pains in the head, sometimes at the point of disease, sometimes in the opposite point; these pains may be fixed, erratic, permanent, intolerable, sometimes intermittent, and often take the lead of all the other symptoms. As in other diseases of the brain, the sensibility may be extinct, or exalted, which is more uncommon; the senses are almost always more or less affected.

The following are the various forms under which cerebral softening may occur. 1st. Sudden loss of consciousness with simple paralysis; 2nd. Sudden loss of consciousness with contraction; 3rd. Sudden loss of consciousness with convulsions, partial or general; 4th. Consciousness intact, intellect somewhat obtuse, sudden alteration of motility; 5th. Consciousness intact, motility becoming altered only slowly; 6th. Softening, no longer revealing itself by the usual symptoms; and finally softening without any symptoms.

Induration is more rare than softening of the brain; it is the result either of an organic process which, in the fœtal state, has disorganized the brain, or in the adult age, of a chronic affection of the medullary substance. We related several cases of it in speaking of cerebral hypertrophy in paralytics in the state of demency. We find it pretty frequently associated with atrophy of one lobe in idiots and epileptics, whose extremities are distorted on one side of the body. I have mentioned several cases of this under the head of idiotcy.

Cerebral induration always affects deeply the intellect, motility, and sensibility; its most common symptoms are idiotcy, epilepsy, contraction, distortion of the limbs, tic of the face, a jumping instead of a walking gait, paralysis, and complete insensibility. The hypertrophic induration that we have met with in persons attacked with general paralysis, has exhibited all the symptoms of acute or chronic inflammation.

It may affect an entire lobe, or both lobes at the same time, or it may be confined to some particular nervous centre, such as the optic tract, the cornua ammonis, the pons, bulb, corpora olivaria, and in the cerebellum, to one of the lobes, or to the middle lobe. I once found it affecting the posterior part of the two lobes of the cerebellum.

IV.

CEREBRAL HEMORRHAGE.

We have seen that violent congestion presents the principal symptoms of hemorrhage, sudden loss of consciousness, paralysis in all its varieties, coma, and death; in the case of congestion we named diffused hemorrhage through all the cerebral capillaries. We now observe this congestion making an eruption into the interior of the nervous substance, and forming a focus of blood, giving rise to a morbid action, in itself constituting a fresh disease.

In closely observing the fugitive and remote symptoms that precede hemorrhage, it is impossible not to admit the existence of a preparatory process in the nervous tissue itself; there is sluggishness of mind, a tendency to sleep, fatigue, and general depression that to me seem quite characteristic. In other cases, the symptoms are the reverse of these, viz.: general excitement, desire of being in motion, and intellectual superactivity, all these symptoms denoting sufficiently that there is already a diseased focus in the brain. The hemorrhage has also been attributed to the tenuity of the arterial walls, which have no cellular coat in the brain. This second reason is very admissible in corroboration of the first.

The hemorrhage may occur in various parts of

the brain, its most usual seat being the optic tracts, the corpora striata, and the parts of the hemispheres that are on the same level with them. The corpus striatum is traversed throughout its entire length by an artery of some size, giving rise to numerous branches which may readily afford source to a hemorrhagic eruption. The hemorrhage may leave the corpus striatum untouched, unfiltrating the parts of the cerebral lobes external to it; in adults it is frequent in the convolutions. It has been thought that in old people the hemorrhage may be veinous, owing to the facility with which the veins become dilated.

When it takes place in the ventricles, it results most frequently from a rent in the neighbouring parts; after the hemispheres it occurs most frequently in the pons varolii, it is rarely met with in the cerebellum.

The blood focus is of various sizes, from that of a pea, or nut, to a large cavern in the middle of the cerebral lobes; it may occupy but one focus, or be disseminated into several small ones. The blood has not the same appearance at different periods of the disease; being at first liquid and dark, it soon assumes the consistence of currant jelly, then gradually becomes brown and more solid, until by the progress of reabsorption, nothing is left but a sort of calcareous residue with cellular bands. The blood may proceed from the rupture of a large vessel, or from exhalation from the capillaries without the appearance of laceration of any considerable vessel. When the hemorrhage does not prove fatal, the work of reabsorption is soon set up; a cellular cyst is formed, enveloping the blood. This cyst exhales serum, which mixes with it, dividing it into small clots, and thus favouring reabsorption; the blood by little and little disappears, and nothing is left at last but a little serum, a small citron coloured kernel surrounded with bands and vessels. Such is the first phenomenon leading to the cure of cerebral hemorrhage. But the organic process does not stop here, but it continues after the blood is reabsorbed, until the cyst itself is gradually removed, and nothing is left but a white cicatrix. Sometimes in the place of the cyst, a reddish white mass is found, traversed by veins, and appearing to be a tissue of accidental formation; this substance of a spongy nature is found in persons who have remained hemiplegic.

The work of reabsorption varies with the activity, age, and vigour of the individual; but it will in general take five or six months before the cicatrisation is completed; the cerebral substance, however is not reproduced, as has been asserted, the union of the parts is effected by means of accidental tissue.

It is important to examine the state of the blood-vessels: they are often studded with steatomatous, cartilaginous, or osseous patches, and these alterations, are undoubtedly one of the most frequent causes of their rupture in the aged; they are sometimes also remarkably friable. Lacerations have been found in the plexus choroides, in the basilar artery, the communicans of Willis, on the arteries of the cerebellum, and on the surface of the brain.

The hemorrhagic focus often presents no trace of nervous matter, amd it is only found surrounding the clot, torn, crushed, or reduced to a reddish pulp, and in its room, the cellulo-vascular substance clearly dissected. Doubtless this state of softening had preceded the hemorrhage, as the precursory symptoms indicated, and in confirmation, we find in some cases softening, red points shewing the orifices of vessels, as well as red spots of larger size, which are small effusions, as well as effusions in considerable quantity.

The nervous pulp surrounding the hemorrhagic focus is always of a clear or dark yellow, or violet; and this change of colour doubtless depends on imbibition. Its consistence may not be changed, although the imbibition must be considered as a frequent cause of the softening that takes place after hemorrhage.

Besides the central hemorrhage, the whole brain shows a general congestion, sanguineous turgescence in the encephalic mass, and great engorgement in the sinuses and other vessels. The turgescence is greatest at the early stage of the hemorrhage, and it is only when it begins to abate that the symptoms begin to show amendment, especially in the intellectual functions. The rest of the mass of the brain may be influenced in another manner. Thus, the blood often bursting through the septum lucidum, passes into the other ventricle, compressing the healthy hemisphere, and stopping its functions; and as the apoplectic symptoms depend as much on the congestions, and consequent compression, as on the hemorrhage itself, these facts should be taken into consideration.

The symptoms of cerebral hemorrhage may be distinguished into the precursory, such as stupor passing congestion, and depression; those arising from the effusion of blood itself, from compression and laceration of the brain; and those which arise from complications, such as softening, inflammation, congestion, or other lesions consequent upon the hemorrhage.

Paralysis is a constant symptom, and when it comes on suddenly, or persists for a long time it is a characteristic symptom; it only diminishes and disappears with the progress of absorption evacuations of blood favour the amelioration of the symptoms. The paralysis is greatest at the moment when the effusion takes place, and may become aggravated, if a fresh hemorrhage be added to the first. The commencement of the paralysis is almost always announced by weakness, slight numbness or a sense of weight in the limbs; the patient is observed to let what he may be holding in his hand drop, or to stumble at the slighest obstacle. I remember the case of a person, who was only sensible to the impression of cold of the night vase on one side; a week after this, he had an attack of cerebral hemorrhage.

Paralysis, a functional symptom, which according to Andral of itself indicates a hemorrhage, not only varies in intensity, but in the symptoms it presents according to the difference of its seat. In the brain, the paralysis affects the whole body the limbs, and is general when the hemorrhage extends to both lobes at once, or is so considerable as to burst into the opposite lobe, and compress it. In such a case, if we raise the limbs they fall again like inert masses. The most common paralysis is hemiplegia, occurring suddenly and persisting; it may affect the whole side, or what is more frequent, one limb of that side; a corresponding paralysis of the face is then observed, the mouth being drawn to the unparalyzed side, thro' the want of antagonism in the muscles of the affected side.

Hemiplegia always attacks (and a few exceptions cannot invalidate this rule) the side opposite to that on which the effusion takes place. The tongue too may only be paralysed on one side, and when the patient thrusts it out, it turns it to one side, the deviation does not always take place on the same side; it usually turns to the paralysed side, altho' it is sometimes observed to turn to the opposite side. These differences no doubt depend on the extent and sort of disease in the centres from which such a number of nerves are distributed to the muscles of the tongue.

The fact of crossing paralysis, may however be taken as a general law, in cerebral hemorrhage, and anatomy explains it by the crossing of the fibres of the upper part of the medulla oblongata. Some cases have been related, which seem to establish the probability of a direct paralysis on the diseased side. But may they not be the result of anomaly of structure? May there not be sometimes juxtaposition, instead of crossing of the fasciculi in some cases, as we have now and then, displacement of the heart?

The hemiplegia may be more intense in the upper than the lower limb. Some writers have thought that the hemiplegia was complete only when the hemorrhage occurred in the middle lobe of the opposite side—that the lower limb was only paralysed when it occurred in the corpus striatum—and that it was confined to the arm when it occurred in the optic tract. I have myself most commonly met with paralyses of the upper limb coinciding with alterations of the posterior lobe. But the more we examine the more we become satisfied of the impossibility of attaching paralytic symptoms to lesions in any given seat, as the structure and nervous susceptibility of each individual, the extent and relations of the lesion with the surrounding parts, produce, in paralytic symptoms, combinations so various, that we must confine ourselves to general results.

When a hemorrhage occurs in the convolutions, it may also give rise to paralysis. I have no doubt in the case mentioned by myself, that the alteration, although situated in the upper part of the brain, interested the extremity of some nervous fibre of the fasciculi, arising from the medulla.

It has been stated that when the hemorrhage occurs in the mesocephalon, the symptoms of the paralysis are general; but the facts shew that very often in this case the symptoms are those of hemiplegia only; when it occurs in the cerebellum, still the symptoms of paralysis are oftener crossed than direct, and they are direct only when the hemorrhage occurs in the spinal marrow.

In the muscles of the face the paralysis is observed always on the same side as the paralysis of the limbs, only from the want of antagonism, the mouth is drawn to the opposite side.

Once the paralysis is produced, it may last a long time, giving rise in the affected limb to a diminution of its nutrition, and consequently atrophy. It may remain stationary for years. When it has a tendency to disappear, the amendment proceeds gradually: the cheeks, lips, tongue and limbs successively recover their motility; but the lower limbs remain weak for a long time.

The lesions of sensibility that most commonly precede cerebral hemorrhage are coldness of the limbs, numbness, and certain prickings in the skin of the fingers; these sensations are usually felt in the limb that will be paralysed although they may occur generally. When the sensibility is abolished at the same time as the motility in a limb, and the disease tends to a cure, the sensibility is almost always restored before the power of motion. The disturbance to which these lesions give rise before the attack is greatest in the organs of the senses, some think they see flies before their eyes, or a fog or small atoms floating about, or the natural objects coloured red, black, or green. Some see double, and this affection with some is transient, while with others it is permanent, and in some cases, the sight becomes unusally powerful.

The sight may be lost on both sides or only on one, and in this case, the alteration must occur on a level with the commissure of the optic tracts; the upper part of the tracts might be affected without causing blindness. But the blindness often occurs in the case of an effusion which occurs at a distance from the optic tracts, as for instance, in the cerebellum. The dilatation or contraction of the pupils depends also on the same lesions.

Lesions of the intellect are shown before the attack by sluggishness, and remarkable inaptitude of the mind, a continual tendency to repose, and drowsiness, and by momentary failures of the memory. After the attack, it is always more or less disturbed; but the patients are very anxious to conceal their feelings, unless the attack is very considerable. The intellectual operations are also disturbed, when the hemorrhage occurs in the cerebellum and mesocephalon, whether it be, that these organs, take share in the acts of the intellect, or that their diseases affect them secondarily.

Throughout the cerebro-spinal axis, there prevails a general consent, by virtue of which, the derangement of one point produces secondary disturbance in the other parts; in this manner, a small circumscribed hemorrhage occurring in the anterior pyramidalia has been known to abolish the intellectual functions completely.

In cerebral hemorrhage, the other lesions of the intelligence deserve to be carefully studied.

When the effusion is small, the patient is soon aroused and recovers his faculties. Scientific and learned men resume their wonted [illegible] with fresh ardour, but can no longer discover in their productions the vigour of thought and [illegible] of imagination, by which they had been distinguished long before, by a gradual [illegible], and an inability to sustain an ardu[illegible] for any time. The last productions of celebrated men arrived at old age, bear the stamp of this decay, which at the same time excites respect and pain. Successive attacks of hemorrhage lead to a state of childishness and imbecility, which puts an end to all his habitual relations, making him laugh, or cry without motive, and giving rise to momentary bursts of demented furor, sometimes a febrile delirium supervenes, depending generally on some complication of encephalitis.

The most curious lesions of the intellect are those that occur singly, such as the loss of speech, or of memory, or even the partial loss of one of these faculties. Speech may be affected partially or completely, the patient being unable to articulate certain words, or letters. The tongue being but an instrument, and articulation being only a result of the associated action of the other muscles of the mouth, pharynx and larynx, we can only rationally attribute the lesions of speech to the nervous centre from which the nerves moving these muscles arise, and this centre is the corpus olivare.

There may also be partial lesions of the memory from an attack of haemorrhage even when the rest of the intellectual functions appear intact. Some hemiplegic patients resume the management of their affairs with perfect lucidity, but they cannot remember proper names, substantives, adjectives, numbers, and these partial losses of memory, which however shew that there still a morbid process going on in the brain, may be independent of any other lesion of the intellect.

There is a particular symptom which I have often observed in old hemiplegic patients reduced to demency viz, a strong disposition to masturbation. It may be that the hemorrhagic focus becomes a cause of excitation to the nervous fasciculi, exerting an influence on the genital organs, and especially on those of the cervical portion of the spinal marrow.

In other patients we observe other phenomena, no less singular. Some are impelled to move constantly forward. There is a hemiplegic patient at Bicetre, who can only stop himself by placing himself against the wall. Some, after advancing two or three paces, make suddenly five or six backwards, as if they were forced by a spring. I am acquainted with a hemiplegic patient, who has partially recovered mobility, and who, when he has advanced about fifty paces, describes, in spite of himself, two or three circles running, and then begins to walk gently again. In some we observe an inclination to turn, to *pirouette*. All these varieties of lesion depend on the nervous centres being affected, such as the corpora striata, and the crura of the cerebellum.

ORIGINAL CONTRIBUTIONS.

CASE OF COLLAPSE FROM EXPOSURE AFTER EXCESSIVE DRINKING.—DEATH.

By John Alexander Morris, Esq., Surgeon.

On the 29th of June at 9 o'clock, a.m., A. B was brought to me presenting the following appearances. Profound insensibility, deep and difficult stertor, yet unaccompanied by any apparent movement of the ribs or respiratory muscles; entire body perfectly cold, and rigid as marble; skin dry and insensible to the touch; tongue slightly protruding, slight foaming from the mouth, lips cold and of a purplish hue; jaws nearly but firmly locked; eyelids closed; pupils insensible to light. The continued application of the vapor of the Aqua Ammon. Fort. for about five minutes produced no sensible effect, with the exception of a slight but momentary modification of the breathing in the form of an attempt at a deeper inspiration. Action of heart, carotid, and temporal arteries imperceptible. I learnt from the [illegible] that the patient was brought on a [illegible] that he [illegible] addicted, at long and [illegible] intervals, to drinking to excess; whenever his [illegible] or opportunities permitted, he could indulge [illegible] largely without inducing intoxication; that on the preceding evening both had been drinking until the patient not being able to stand was compelled to lie by the side of a ditch on the highway, where he was suffered to remain by his companion, who went home under the asserted opinion that probably he might return to his senses and take care of himself; on proceeding, however, to the spot on the following morning he discovered him in nearly the exact posture in which he was left; he had therefore remained exposed to the night air during eleven hours, at the expiration of which he was found in the state I have just described.

The man evinced no symptom from which I could augur a favorable result, and I feared lest dissolution might take place before sufficiently active measures could be put into operation; I directed, therefore, that he should be vigorously rubbed over the region of the heart and abdomen with strong Aqua Ammon. a bottle of which was also kept applied to his nostrils; the bladder was emptied and from the quantity of water drawn off seemed to have been in a state of considerable distension. No appearance of resuscitation whatever succeeded these measures, although persevered in without intermission for about three quarters of an hour, the pulse however, and the action of the heart became perceptible. Under these circumstances, I got him immediately stripped and placed in bed, supported by an attendant in an upright position, his legs immersed up to the knees in a bucket of water of about 100° into which were thrown four handfuls of common salt; each hand to above the wrist was also subjected to the same treatment, the temperature of the water in which they were immersed being considerably under that in the bucket. I was surprised to observe that the heat seemed to act more sensibly on the hands than it did on the feet as was evinced by his making efforts to remove them; the body during this process was well wrapped in blankets. Immediately on the immersion of the feet I observed a diminution of the circumference of the neck gradually but perceptibly take place, and the head become more flexible on the shoulders. I now attempted to induce vomiting, by tickling the throat and fauces, for the purpose of aiding in rousing the oppressed powers of the system; a scanty quantity of thick mucus was the only result. After the lapse of a little time I injected into the stomach a solution of four grains of Tartar Emetic and followed it with a copious supply of warm water, until the stomach, being completely charged, was forced to reject it. The effort thus caused was succeeded by easier respiration which now lost its peculiar laryngeal character; the jaws became a little more relaxed and the tongue somewhat receded. The hair was now cut off and cold applied to the head; six leeches to the temples and dry cupping to the nape of the neck. The water in which the feet had now remained for nearly an hour, was removed and replaced by water of a considerably higher temperature. The hands were similarly treated, and about half an ounce of hartshorn largely diluted with cold water was injected into the stomach; vomiting was shortly after induced and the stomach again charged with cold water and hartshorn, which was immediately after succeeded by the affusion on the vertex of the head of a gallon of cold water, allowed to pour from the spout of a kettle at a height of three feet in an uninterrupted stream; not the slightest evidence of returning sensation followed these continued and energetic measures and I began to give up all hope of saving him. Soon after the cold affusion, however, and about half an hour after the renewal of the water, I could distinguish slight mobility of the pupils, the jaws were relaxed, the breathing again assumed its stertorous character, and the ribs and respiratory muscles their legitimate functions, after a long cessation; the face became more developed, and the whole body was in a few seconds bathed in profuse perspiration, his shirt was completely saturated with it, and it flowed in innumerable currents over the entire surface of his body; he was now well dried and the feet and hands removed from the hot water; the former were well blistered. He was laid in bed with the head slightly reclining backwards, and the shoulders elevated as being the most convenient posture for easy respiration. In the course of a few minutes copious vomiting ensued which was encouraged. This subsiding without any amendment whatever taking place, I, as a last resource made a quart of the strongest infusion of black tea which, with about three drachms of spirit of hartshorn in a pint of cold water, I threw into the stomach, and left him at 2 o'clock, p.m. having remained with him five hours. I calculated on the occurrence of dissolution early the following morning, and thought no more of the matter until 5 o'clock in the evening when I received a message from the nurse in attendance that he had returned to a state of almost perfect consciousness. I immediately visited him and found him to my great astonishment sitting up in the act of drinking copiously; his face was red, eyes injected, speech quite consistent but enunciated with slight difficulty; his manner and appearance were those of one waking from a drunken fit yet not quite free from its effects, his pulse was strong, full, and regular. These appearances began to manifest themselves immediately after my departure. After giving directions respecting the applications to be made to the blistered legs I left him, cautioning the nurse to watch him narrowly, and despatch a messenger to me the moment the least appearance of collapse should set in, and to administer nothing with the exception of cold water or cold whey. Between 11 and 12 o'clock of the same night I received a message that he was dying, I went immediately and within ten minutes after my arrival he died. From what I could learn of his history after I left him at 5 o'clock, it appeared, that immediately after my departure his pulse began to waver and his manner to look suspicious. These symptoms continued progressively assuming a more decidedly threatening aspect until 11 o'clock, when, no symptom remaining from which to augur favourably, I was summoned to witness his dissolution. On *post mortem* examination sixteen hours after death the brain was found loaded with blood, an appearance which may partly be accounted for by its having gravitated to that organ during its depending position after death. The ventricles and lateral sinuses contained a small quantity of serum; no other abnormal appearance presented itself. The stomach and intestines were simply vascular, but the liver was perfectly healthy. The man was strong, of a well developed muscular system, and evidently of a robust constitution. I regard the cause of his death to be collapse succeeding a high and long-continued excitement. The case I conceive to be rare and interesting as evincing the necessity of unremitting vigilance, and the prosecution of a system of careful but bold stimulation. I should have observed that no spirituous smell could at any time be perceived by me, although I sought for it during his life as well as at the *post mortem* examination. Some of the attendants however assured me that to their senses it was quite perceptible when he was first submitted to treatment. The measures employed to effect resuscitation were very powerful but justifiably so, as it seemed a matter of extreme improbability, if not impossibility, considering his state when I first saw him that he could otherwise have been made to evince even the temporary return to consciousness which took place.

M. Melays, Doctor of Medicine chief of the Anatomical division of the school of Medicine of Rouen has been appointed by ministerial *ordonnance* professor at the school, in place of M. A. Flaubert.

HOSPITAL REPORTS.

UNIVERSITY COLLEGE HOSPITAL.

Reported by J. T. Griffith, Esq., M.R.C.S., late House Surgeon.

DISLOCATION OF THE FEMUR INTO THE ISCHIATIC NOTCH.

Maurice Coghlan, aged 60, an Irish bricklayer, was brought into University College Hospital on the 11th of June, 1845, quite dead, having fallen above 30 feet from a ladder, up which he had been carrying a pail of water. On making an external examination of the body, there was found to be a fracture of the skull, with depression; two or three ribs were found to be fractured on the right side, and the right femur to be dislocated into the ischiatic foramen, with all the characteristic signs of such an accident. The foot was turned considerably inwards—the great toe pointing to the opposite instep. There was seen an apparent shortening of the limb, the right knee being nearly three inches above the left. On measuring, however, this was found to arise from the pelvis on that side being much higher than on the other, no perceptible difference existing on the two sides in the distance between the anterior superior spinous process of the ilium and the external malleolus. External rotation of the injured limb was impossible to any extent, but the thigh could be readily flexed upon the trunk.

On dissecting the gluteal region, a considerable quantity of extravasated blood was perceived among the fibres of the gluteus maximus muscle and under the integuments of the back part of the crest of the ilium, which portion was broken off, and entirely separated from the body of the bone along its whole length. The gluteus maximus muscle was large, and fully developed; it was uninjured, and on raising it from its attachments, the head of the femur was seen completely exposed beneath it, lying over the sciatic foramen, just below the inferior border of the pyriformis muscle, and in contact with the sciatic artery. The great sciatic nerve was stretched tightly over the neck of the bone, and appeared to have burst through the fibres, and got in front of the quadratus femoris muscle, which was completely torn across, as was also the tendon of the obturator externus; indeed the head of the femur appeared as though it had burst through between that muscle and the other external rotators of the thigh, for the gemelli and the obturator internus remained attached to their insertions in the trochanteric fossa; the pyriformis, too, was entire, and as it lay directly above the head of the femur, it did not appear to have undergone much tension. The gluteus medius, at its upper and posterior part, was quite torn from the bone, which was fractured beneath it. The small sci[illegible] nerve was seen beneath the head of the fem[illegible] and a quantity of extravasated blood was found in that neighbourhood; there was also a great deal of blood near the small trochanter, but the tendon of the psoas and iliacus did not appear to have been injured. The ligamentum teres was torn out of the fossa in the head of the femur, but remained attached to the acetabulum. On examining the capsular ligament, it was discovered to have been ruptured at its posterior part only.

The fracture of the skull was found to extend completely across the base, rupturing the internal carotids of both sides during their course through the cavernous sinuses.

GLASGOW ROYAL INFIRMARY.

Reported by WALTER BAIN, ESQ.

COMPOUND FRACTURE OF THE FEMUR—DEATH.

John Orr, aged thirteen, was admitted into the Royal Glasgow Infirmary, under the care of Dr. Hannay, August 2nd, 1845, at four, p.m.

At seven o'clock in the morning he was caught by some part of his dress, upon a revolving shaft in the factory in which he worked, and drawn round along with it several times, his limbs and head coming in contact with some barrels standing near the machinery.

On admission, his right lower extremity was three inches shorter than the left, the foot was everted, and the thigh much distorted there was no pulsation in the popliteal artery or in the vessels of foot.

The right femur is fractured transversely at its middle third: the fractured extremities overlap each other very much, and the lower fragment approaches very close to the integument posteriorly.

The anterior portion seems pressing on the femoral artery, as it is tucked forwards. When the limb is reduced pulsation is restored to the anterior tibial. Over the fracture, and exactly in the mesial line of the thigh posteriorly, is a small wound, large enough to admit a probe, and leading into a large bloody cyst.

Much pain is complained of across the lower part of the chest and upper part of the abdomen. No ribs fractured. Had no vomiting, and passes urine freely and without difficulty.

His face is much swollen and discoloured Both palpebræ infiltrated with blood. There is a small ecchymosed spot on the forehead over the external angular process of the frontal bone, conveying to the finger a feeling as if of a ridge with a portion of bone depressed; but on minute examination, no fracture can be detected Much abrasion of the integuments over and below the chin, and in the mouth about an inch of mucous membrane is torn from the jaw at the roots of the lower incisor teeth, and on the mucous surface of the lower lip is a deep, contused wound, large enough to hold a bean

Has no headache. Pupils are natural. Tongue clean. Pulse 80.

The limb was put up with lateral splints, and hot fomentations applied.

3rd. Patient has passed a restless night. Pulse 108, feeble. He complains much of bruised parts. Urine copious. Ordinary diet.

Contin. fotus. Hab. hor. somni. Pulv. Doveri gr. xii.

5th Swelling of face abated; chin and lower lip painful, swollen, and tense, complains considerably of chest; sound on percussion, and respiratory sounds natural; limb is easy and easily kept in proper position; swelling abating, skin warm; pulse 112; tongue clean; bowels regular.

℞ Sp æth. nitros. ʒij., Vin tart. antim ʒi. potus imperial. lbj. Sumat in dies part. vicib.

7th. Copious discharge of a thin, dark-red fluid from the wound; limb easy, chest less complained of; skin still hot and dry; tongue slightly loaded; bowels natural; pulse 96, of good strength.

Contr. potus. Foment limb as formerly.

9th. Had a short rigor last evening, and a restless and feverish night. The limb is in a tolerable position, but there is much thin, unhealthy discharge from the wound Pulse 96, small, and easily compressed, thirst, but no appetite, bowels natural.

Hab. in dies vin. rubri, ℥iv: Hor. somni hab. haust. c. tr. opii, m. xii.

10th. The draught soothed him, and procured a good night's rest. Pulse 96; improved in strength. Discharge from the wound very abundant, but of better character; no return of rigor; uneasiness in the chest gone; mouth healing; skin moist; tongue clean; less thirst; bowels rather sluggish.

To have beef-tea and arrowroot.

11th. The probe reaches bare bone by the wound; a large abscess in the back part of the thigh; discharge is improved in character, and its free escape is procured by slinging the leg and leaving the opening patent. Is at present quite free from pain, and inclined to sleep.

Augeat. vin. ad ℥vi.

12th. An uneasy and sleepless night from pain in the limb; some return of febrile symptoms; bowels confined.

Hab. stat. pulv. jalap. c., ʒss; et enema commune post hor. ij. Contr. mistur. et vin.

13th. Discharge less and improved in quality; bones easily kept in position by lateral splints. Scultetus' bandage, and fomentations. The limb still continues slung, the opening of the abscess looking directly downwards; febrile symptoms diminished; some appetite.

Contr.

15th. Constitutional symptoms moderate; discharge diminished still more and improved in quality. Relishes wine.

Augeat. vin. ad. ℥vij.

18th. Still slight febrile symptoms; appetite improved. Desault's splint to-day applied; limb laid on a cushion, with an aperture to allow of escape of pus from abscess, which is more healthy. Collection of matter formed in the mouth, discharging itself by the side of some denuded bone.

Contr.

29th. Has remained pretty well since last report till to-day, when he had a severe rigor, anorexia, and vomiting, followed by febrile symptoms and profuse sweating.

Contr. omnia.

30th. The upper fragment of the femur is much tilted forwards; the limb to-day was bent on pelvis, and laid on outer side on a concave splint (the only position which will permit the free exit of pus).

31st. Passed a restless night; much distressed with general irritation, and complains of that part of his hip which rests on bed; febrile symptoms continue, with dry tongue and hot skin.

℞ Aq. acet. ammon. ℥ij., Vin. antimon. Tr opii, aa. ʒss.; Aq pura, ℥iij. Sumat ℥j. tertia q. q. hora. Bibat imperial.

Sept. 1. Febrile state continues; complains much.

Contr.

4th. Restless and almost pulseless; countenance pale and sharp; low muttering; takes no food or wine.

Hab. sp. hordei, ℥ij., c. aq. bullient. et sacchar.

5th Moribund.

6th Died this morning.

The parents would not permit an inspection of the body.

PHLEGMONOUS ERYSIPELAS OF LEG AND FOOT, TREATED BY INCISIONS AND FOMENTATIONS CONTAINING A SOLUTION OF SULPHATE OF IRON. RECOVERY.

John Kennedy, aged twenty-six, an Irish policeman, married, was admitted July 30, 1845, under the care of Dr. Hannay.

Patient is a stout, muscular man, of temperate habits, but much exposed from his occupation to vicissitudes of weather.

Seven days [illegible], after exposure to wet and cold, and, at th[illegible] time, great fatigue, he had severe rigor[illegible]ed by headache, acute pain in left foot and [illegible] heat of skin, thirst, and loss of appetite Shortly after the foot was observed to become swollen and red. Fomentations and poultices were applied, but without relief.

At present the left foot and leg are swollen, œdematous, red, and acutely painful, especially across the instep, where the integument is tense and glossy. At this point there is distinct fluctuation, and the surrounding parts have a boggy feel.

The pain deprives the patient of sleep; skin hot and dry; pulse ninety-six, full and bounding; tongue clean and moist; bowels costive.

Incisions over left leg and foot Low diet.

℞ Aq. acetat. ammon. ℥ij., Vin. antimon., Tr. opii. aa. ʒj., Aq. puræ ℥iij. Sumat ℥j tertia q.q. hora.

31st. Patient expressed himself very much relieved by the incisions, which have bled copiously. The redness and swelling have considerably abated; has had a good night; skin still warm but moist; less thirst; tongue clean, bowels opened; pulse 80.

Contr. mistur.

℞ Sulphat ferri ʒij., Aq. puræ ℥vj, Ft. sol. Admov. p.d. et crur. lintea madef. in hac solut.

August 1. Pain, swelling, and redness remarkably abated; discharge from incisions pretty copious, but healthy; pulse, tongue, skin, and countenance now natural; appetite returning.

Contr. solut. et mistur.

4th. Some increase to-day of pain about three inches above the ancle; the part is tense and shining, and fluctuation is evident. Foot quite easy; swelling nearly gone; discharge scanty

and healthy; incisions granulating; skin natural; pulse 80, full; bowels costive.

Aperiat. abscess.

Contr. solut. et mistur.

Sumat stat. ol. ricini ℥j.

5th. The patient was much relieved by the exit of a considerable quantity of pus, by incision yesterday: swelling nearly gone; tension abated; bowels freely moved by the castor oil; has perspired freely; pulse 74.

Cont. omnia, bibat imperial.

6th. Febrile symptoms gone; takes his food well.

Omittr. omnia,

℞ Sulph. ferri ℥j., Aq. bullient. lbj. Sit pro lotione, quocum madd. sit fasc. scultetus et ped. et cruri applicand.

To have ordinary diet.

9th. The limb is perfectly easy; and the swelling is gone; incisions alone remain to be healed.

Curat. ulc. c. emplastr. adhesiv. et fasc.

10th. The incisions are healed to a point; he has been walking about for a few days; is free from pain and every inconvenience, save some stiffness; general health perfect, though he is considerably less stout than when he was admitted.

Dismissed cured.

CHRONIC ECZEMA. CURE.

George Sutherland, aged 34, a scotch stone-mason, single, was admitted under Dr. Watson, February 25th, 1845.

Over several parts of the surface is an eruption which is said to have commenced about 2 months ago on the arms and to have spread thence over the greater part of the body in 4 or 5 days.

At present the skin of the arm pits, over the flexures of the knees and elbows, of the scrotum and penis and immediately contiguous parts, is red, excoriated and discharging a considerable quantity of a clear fluid.

Around the margins of the red excoriated parts are some thin greenish crusts. Over the abdomen and inner aspect of the thighs are a number of small acuminated milky vesicles surrounded by a red areola and in most instances with a hair in their centres, also numerous small ulcers covered with brownish scabs.

The neck and arms are affected in a similar manner but to a very slight extent; ears and face are scaly and were affected before admission; feet, hands and back are quite free from disease. The affected parts have repeatedly desquamated and there have been several successi[illegible]rops of vesicles. He has constant severe pain and [illegible]tly excessive itching in the diseased skin. [illegible]

Eight months ago he had sy[illegible] for which he took mercury to the extent of affecting his mouth; his general health is said to have been very good. Appetite good; tongue white; bowels regular. Pulse 90.

26th. Fiat venesect. ad ℥xij. Sumat in die, tart. antimon. gr. iij. Aq. puræ ℥vi. ℞. Sulph. aluminis ℥ss. Aq. puræ lbij. Solve, lavent. part. affect. hac solut. mane et vesp. Milk diet.

28th. Iterum mittat. sang. brachio. ad. ℥xij. Add. sol. tart. antimon. tart. antim. gr. ij.

Contr. solut. sulph. alum.

March 2nd. He is in some respects, improved; complains of general itchiness, particularly in the ulcerated spots on his thighs. ℞. Sulph. precip. ℥j. Adip. suill. ℥iij. ft. ungt. adhib. ulcer. femoris regione.

Contr. alia.

7th. The eruption is much better but he complains still of itchiness.

Contr. medicam.

℞. Chlorid. calc. ℥ss. Aquæ puræ lbij., utat. pro lavatione subinde.

9th. Eruption still better. Itchiness remains.

Contr. omnia sed omitt. sol. tart. antimon. Sumat omni nocte. pulv. doveri. gr. xv. et secund. q. q. mane. haust. nig. ℥iij

March 10th. Itchiness has increased very much; eruption looks very much improved.

Omit. medicament.

Descend. omni nocte in baln. tepid., adhib. part. affect. cataplasm. emoll.

℞ Submur. hydr. gr. ij.; Pulv. opii, gr. j. Ft. pilul. o. nocte sumend.; Hab. secund. q. q. mane haust nig., ℥iv.

12th Itchiness somewhat relieved.

Omittr. cataplasmat.

Curent. part. affect. c. ungt. oxid. zinci.

14th. His complaints are again increased, and the discharge from the diseased parts is copious.

Contr. pilul. et haust. nigr.; omittr. omnia alia.

℞ Pulv. tart. antimon., gr iij.; Aq. acet. ammon. ℥i; Aq. puræ, ℥v. Sumat ℥j. quarta q. q. hor.

℞ Hydriod. potass., ℥ iij.; Aq. puræ, lbij. Solve; utat. pro lavatione ad part. affect. mane et vesp.

17th. He is feverish to-day; eruption much as formerly, pulse full and quick.

Omittr. lot hydriod. potass.; contr. sol. tart. antimon. Fiat V. S. ad ℥xij. Lavent. part. affec. c. sol. sequent.

℞ Aq. acetat. Ammon., ℥iij.; Sp. camphorat., Aquæ puræ, aa. lbj. M.

18th. Blood drawn yesterday is buffy; patient still feverish; eruption more painful, red, and irritable.

Adhib. ulcer. cataplasm. emoll. et cras. mane. hirudin. viij. Contr. alia.

20th. Rept. hirud. xij. Contr. alia.

21st. Rept. hirud. xij. iterum.

Contr. alia.

25th. Eruption much the same; fever gone.

Contr. omnia.

27th. Not much improved.

Omittr. medicine. omnia.

℞ Decoct. Sarsæ, lbj; Sol. arsen. Fowler., *m.* viij. In die sumend.

Adhib. ad cutem rubent. pulv. tritici.

30th. Again somewhat feverish; pulse 104, full; skin much the same; several parts discharging considerably.

Adhib. cataplasm. emoll.

℞ Aq. calcis, ℥viij.; oxymur. hydr., gr. viij. Solve; lavent. part. exudent. hac sol. ter in die.

Contin. alia.

April 1st. Redness, discharge, itchiness of skin, somewhat relieved.

Contr. decoct. c. sol. Fowlerian.; Adhib. iter. pulv. tritici.

3rd. Again complains of excessive itchiness; discharge from skin slight; general health improved.

Contr. omnia.

Hab. hor somni. pulv. Doveri. gr. xv.

4th. Omittr. pulv. tritici.

℞ Aq. acetat. ammon., ℥iij.; Pulv. tart. antimon. gr j. Syrup. simpl. ℥j.; Aq. puræ, ℥iv. In die sumend.

Contr. decoct.

9th. Improved; some pain of the thighs.

Fricet. femor. c. ungt. simpl. Mane et vesp.

Adhib. hirud. vj. part. dolent.

10th. Complains of sickness; skin rather hot. Bowels regular; leeches have relieved. Omittr. Decoct.; contr. mistur. salin.

11th. Skin improved but still feverish with considerable cough. Adhib. C. C. ad stern. super., ut. educant. sang. ℥vj.

Contr. Mistur. salin. diaphor.

18th. Is again free from fever. Rept. decoct. sarsæ c. sol. fowler. contr. mistur. salin.

20th. Some pain in the left thigh. Adhib. hirud. vi. ad femor. sinistr.; contr. alia.

21st. Iterum adhib. hirud. viij femor. sinistr.

28th. Complains still of his limbs; adhib. cataplasm. emoll. part. dolent.

May 3rd. Legs remain the same, particularly the left. Otherwise he is nearly well.

Adhib. cruri sinistr. lintea c. decoct. ulmi madefact.

13th. Much improved; left limb still a little irritable.

Adhib. hirud. viij. ad. crur. sinistr.

Contr. alia.

June 4th. Has improved rapidly since last report. His disease is now entirely gone, except in left lower extremity, which is still affected, but to a much less extent than formerly. Skin of affected parts a little tender; scaly laminæ of cuticle peeling off.

Omittr. medic.

7th. Dismissed; cured.

COMPOUND FRACTURE OF CRANIUM; DEPRESSION OF BONE.—RECOVERY.

July 29, 1845. John Rankin, aged 13, a school boy, was admitted at half past 12 p.m. under the care of Dr. Hannay. An hour before admission the patient was said to have received a blow on the crown of his head from a brick bat, which fell from a height of four stories.

On admission, he lay quietly in bed on his back, his eyes were shut, expression quite calm, and respirations natural. When spoken to he seemed much annoyed, and when touched opened his eyes, moved his limbs violently and cried out loudly, relapsing again into his quiet and relaxed state immediately on being let alone. He did not put out his tongue when asked. Pupils widely dilated and insensible to light; urine been passed in bed. Limbs cold. Pulse 40.

Over posterior part of left parietal bone is a clean incised wound of the scalp 3 inches in length, at the bottom of which the skull is fractured and a portion of considerable extent depressed to a depth equal to the thickness of the bone. Depressed portion is triangular in shape, and a fissure is found running forwards towards the sagittal suture. There is no swelling or puffiness around the scalp wound. On right side of forehead, an inch and a half above the orbital ridge is a small circular wound with considerable surrounding ecchymosis and in which bone is felt bare. There has been no bleeding from ears and very little from wounds.

Hab. stat. fotus pedib. Injiciat. stat. enema terebinth. Abradt. capill.

2, p. m. He lies on his back, and his limbs are bent in the most relaxed manner; he cannot be made to speak or exhibit any consciousness, though his external senses are entire. No convulsions or paralysis. Left pupil is contracted and very dull, the right dilated and insensible. Pulse 64. Respirations 22, calm and full. Temperature restored. Eyebrows knitted, though his expression otherwise calm. Injection operated, dejection scanty. Occasional vomiting. Milk diet.

℞. Calomel. gr. vi. Pulv. Gambog. gr. viii., ft. elect. ℞. Calomel. gr. ij. Pulv. Jacobi. gr. ij.; ft. pulv. sumat j. tert. q. q. hora.

30th. He lay quiet till one this morning; he required an enema after the powder, when the bowels were freely moved; stools passed unconsciously and in bed. At present he lies on his back like a person in calm repose. Pupils similar in size; responsive to light but sluggish; no swelling, redness or tenderness around wounds. Pulse 60. Small, slow and regular. No vomiting; swallows readily. Voids urine in bed without being conscious of it.

Sumat pulv. iv quarta q. q. hor. tant. Injiciat. enema domestic. quamprim. et [illegible] vesp.

Pupils, though sluggish, [illegible] nearly natural; some improvement has taken place as regards consciousness; he is occasionally restless and difficult to manage; pulse 72, of good strength, regular and soft; heat of scalp moderate; wound free from tenderness, redness, and swelling. One free dejection has occurred, and he has passed a large, lumbricus teres.

Contr. pulv., et injiciat. enema domestic. s. o. s.

August 1. Some small improvement of consciousness; still lies in a drowsy state; pupils still sluggish; occasionally restless; bowels freely opened; pulse 72, regular. Urine and dejections passed in bed, and apparently without his knowing it. Wounds as yesterday.

Sumat pulv. 8va. q. q. hor. tant. utat. lotion frigid. p. r. n.

2nd. Expression improved; opens eyes and gazes around him; answers yes and no, but seemingly without understanding the questions asked; yawns frequently, and seems drowsy. Urine and dejections passed in bed, the latter consisting chiefly of mucus and blood. Wounds as formerly. He has taken some porridge and broth with apparent relish. Pulse and skin as formerly.

Omitt. pulv., contr. lotion. frigid.

3rd. Consciousness and intelligence slowly return-

ing. To-day he desired to get out of bed, when having a stool. When asked to show his tongue, he gazes fixedly, but does not betray any token of understanding the request; still heavy and drowsy, but easily aroused. Pupils now natural. The wound on the forehead has healed, and the posterior wound is perfectly healthy; pulse now natural, but towards evening it becomes quicker, with some heat of skin.

℞ Sp. æth. nitros. ʒij., Vin. antimon. ʒi, Potus imperial. lbij. Part. vicib. in dies bibend. Hab. pulv. hydr. c. creta ʒss. in chart. viij. equal. divid. Sumat j. decoct. avenæ 8va. q. q. hora.

4th. Still sluggish, somewhat confused, and lethargic, but easily roused; seems to know the persons about him; takes some nourishment; bowels relaxed; pulse 72.

Contr. omnia., sed sumat pulv. ter in dies taut.

7th. Has continued to improve in the same gradual manner, and now his consciousness and natural appearance are quite restored. His pupils are natural, and he sleeps well, and takes his food with relish; he voids his urine and stools with perfect consciousness, and answers rationally. The wound is well, the scalp cool, and the skin cool and moist. There is still slight confusion and a fixed, unmeaning gaze, however; some slight irritation of the ●ctum, mucus, and traces of blood in stools; pulse 68.

Rept. abras. capill.; contr. potus.

8th. Much as yesterday; answers rationally, and speaks of home and affairs there; pulse, tongue, and skin, natural.

Contr.

10th. Frequent natural dejections; no complaint. To have beef-tea and rice for diet.

Contr. alia.

11th. Wound on the scalp is uniting at each extremity; the bone is bare at the bottom of wound, of an ivory colour, and no granulations are present on or around it. Free from complaint.

Omittr. medicament.

14th. Continues well. Wound filling up at extremities; slight discharge,

20th. Wound nearly filled up, save a small position in centre, leading down to bare bone. Is in perfect health; occasionally gets out of bed; feels tolerably strong.

27th. The patient's parents wish to take him home, as he has gone on well since last report. Wound as before; slight discharge.

Dismissed.

Sept. 24th, 1845. Since his dismission from the hospital, the patient has come up about once a-week to have his head examined. He walks up unaccompanied.

Small pieces of the outer table of the fractured and depressed portion of bone have come away, and the wound is now nearly healed.

A depression can be easily felt through the scalp. His general health is perfect.

REVIEWS.

Anatomical and Clinical Researches on Various Diseases peculiar to Infancy. By F. L. Legendre, M.D., interne and laureate (gold medal) of the hospitals of Paris. Paris, Masson. 1846. 8vo. p.p. 449.

The work before us is the result of several years' attentive and fruitful observations. It contains valuable practical results, and most accurate researches in morbid anatomy. It may not therefore be out of place to lay before our readers a rapid sketch of its leading chapters, particularly as it will afford us an opportunity of bringing forward the opinions of the best French authors, on the most disputed points of the diseases of infancy. The discrepancy of statements relative to some of the most important points, and, to those it would seem, most easily ascertained by statistical research, may be explained by the fact, that, it is only during seven years, that an hospital has been opened in Paris for infants under two years of age: every assertion therefore of M. M. Louis, Rilliet, and Barthez, and even of Dr. Legendre must be considered to apply more particularly to children of more advanced years.

M. Legendre studies in separate chapters, tubercular meningitis, meningeal hemorrhage, pulmonary inflammations, scarlatina, diarrhœa, etc. We will confine ourselves in our first critical remarks to the analysis of the two first chapters.

Tubercular Meningitis.—M. Legendre begins this chapter with the assertion, that general tuberculisation is observed more commonly between the ages of six and fifteen, than at any other period of infancy. On this point he agrees perfectly with M. M. Rilliet and Barthez. Dr. Louis on the contrary states, that in childhood tubercles are common between two and eight years, and diminish in frequency from that period, to puberty. Professor Trousseau, on the other hand, distinctly asserts, that under two years, more infants are carried off by consumption (tubercular), than by all other causes of dissolution put together. Our author distinguishes two forms of meningitis, according as the cerebral symptoms are noticed in subjects apparently healthy, or in infants evidently labouring under a tubercular diathesis. The distinction is one which must strike all those who have had opportunities of personally observing numerous cases of meningitis; this classification would however, have much gained in value, if Dr. Legendre had pointed out the diagnostic marks, which separate his first form from essential meningitis. The symptoms of the disease occurring in apparently healthy children, are, according to Dr. Legendre, remarkably regular in their succession, — not so, in the second form: the morbid cerebral manifestations are obscure, and often cause some hesitation in the diagnosis. The description of the progress of the disorder is most accurate: — The irregularity of the pulse, and the changeable nature of the paralysis, during the second period are pointed out with care: we should have wished to have also M. L's opinion of the value of Professor Trousseau's sign—the macula meningitica,—the importance of which we have often seen tested by practical experiment. Two other remakable appearances are insisted upon by the learned authority, we have just quoted: the first of which is the singular irregularity of the respiratory movements. If the comatose infant be watched attentively, he is seen to sigh deeply, and to make two or three rapid inspirations; an interval then occurs, which sometimes lasts so long as forty-five or fifty seconds, when the respiratory movement is again repeated. The other circumstance to which we refer, is the length of time, during which infants affected with meningitis preserve their flesh, contrasted with the extreme rapidity, with which the cellular tissue is absorbed in other acute disorders. All these symptoms mark the destruction of the connecting link between cerebral influence, and the function of nutrition, and as such deserve a place in the history of meningitis.

In the morbid anatomy of the malady, M. L. remarks the absence of pus in a *liquid* state; the constant integrity of the arachnoid membrane has also fixed his attention. The granulations of the pia mater, alone, are seldom in M. Legendre's opinion the cause of death: they are however the proximate cause of cerebral inflammation. In no one instance was the tubercular production limited to the envelopes of the cerebrum. M. Legendre's observations bore upon twenty-eight subjects, and in three-fourths of the cases, tubercular matter was found in more than three organs. When the patients had died from the progress of the second form of disease, the only anatomical difference was the more advanced state of general tuberculisation. The method of treatment recommended, in this almost constantly fatal malady, is local depletion, by the application of leeches to the pituitary membrane, and the exhibition of calomel in minute hourly doses.

Meningeal Apoplexy.—This is the only form of apoplexy noticed in children, it is the occasion of a peculiar form of hydrocephalus. Seven cases fell under M. Legendre's observation, during the space of two years, and permitted him to investigate the anatomical characters of the disease. Death occurring from the eighth to the twelfth day from the invasion of the symptoms, pure blood could not be met with in the arachnoid. Clots flattened by pressure to the shape of membranes, were however observed, and collections of bloody serum, varying in quantity from six to eight ounces. In general the hemorrhage occupied both sides of the head, no great enlargement of which was noticed; the sutures and the anterior fontanelle, however had not united. When life is prolonged beyond the first period of the malady, a cyst is formed, always attacked to the parietal arachnoid, by adhesions, and free from any attachment to the visceral portion of the membranes: the quantity of liquid contained in the cyst has been found equal to a pound and half, but M. Legendre never met with more than twelve ounces. The symptoms of the first period consist of fever, marked by heat of skin, and a quick *but regular* pulse, contraction of the hands and feet, and convulsions. M. Legendre never noticed any sort of paralysis. The great practical deduction, to be gathered from this chapter is that chronic hydrocephalus, arising from meningeal hemorrhage, is a disease in which more sanguine hopes are warranted, than in ventricular hydrocephalus. The diagnosis, between the two forms, is therefore a point of first-rate importance, and rests upon the following facts:—ventricular hydrocephalus, begins at, or soon after birth, and the head may acquire an enormous magnitude: arachnoidian hydrocephalus, begins only eight or ten months after birth, the head never acquires a very considerable size, and the disease is marked at its first appearance by fever and convulsions. For the treatment, of the acute stage, M. Legendre recommends cold applications to the head, and revulsion on the lower extremities. During the second period, he is of opinion that absorption of the fluid might be hastened by revulsion on the head, calomel internally, and diuretics. Compression of the head is also advised, but this method should be employed with the greatest prudence, We should not forget, that a learned professor, having employed this method, without the necessary precautions, the child died from rupture of the basis of the cranium.

TO CORRESPONDENTS.

C.—*The details of the "Fellow election" are not worth entering on. No gentleman was disgraced by being passed over: no "fellow" was honoured by being chosen.*

K.—*Though the grave-yard nuisance is not abated we have no doubt it will be. It is doomed. We have not overlooked the question.*

A Student *is thanked for his information.*

Justus.—*The letter cannot be inserted, because not authenticated.*

M.D.—*The matter is under arrangement. With respect to the Provincial Association, our correspondent may be convinced of the truth of his opinions, so disparaging to the members, who are general Practitioners, but he has failed to convince us.*

Medicus, *in allusion to the Fellows' dinner, writes, "Hear it, ye members of the Royal College! engrave it on your memories! your President declares, in the year of our Lord,* 1846, *'That the Council would resolutely persevere in their unpopular courses, if supported by the Fellows,'* '150 *of whom, it is said, received the assurance with enthusiasm!' What immaculate young gentlemen they must have been! It is not possible, surely, that such fellows can be at large in the nineteenth century? They must be restrained, or the scientific character of the Medical Profession forfeited."*

Mr. Morris *will find his paper in the present number.*

Mr. Finucane.—*An advertisement inserted in the* Medical Times *would most probably obtain for our correspondent the kind of situation he desires.*

Mr. Yates's *shall receive a private note from the editor.*

A. M. A's *request shall be complied with. We omitted the questions because we considered them unworthy insertion. The great desideratum we believe to be the fee paid for the fellowship.*

Mr. Burke, *surgeon, of Tuam, Ireland, writes,—"The extensive circulation which your Journal commands among pharmaceutical as well as medical men, induces me to make it the medium of communicating the following new and simple test for the detection of a substance with which nitrate of silver is extensively adulterated, viz., nitrate of potash. The suspected nitrate of silver being dissolved in distilled water, tartaric acid is to be added to the solution, which will have no effect if the nitrate be pure; but if potash be present there will be an abundant precipitate. This test is easily applied, and may be relied on."*

A Member of the Oxford Medico-Chirurgical Society *does not receive his papers directly from the office of the* Medical Times. *All numbers sent out from the office to subscribers are carefully and correctly folded: copies obtained through a bookseller are not folded at the* Medical Times *office, and are, consequently, sometimes liable to be paged incorrectly. The same fault occurs occasionally in the* Athenæum, *and, indeed, in all journals of very extensive circulation.*

D. S. S. *will find residence in an University where the degree of M.D. is granted, to be requisite for admission to the examinations of the University of Edinburgh.*

☞ *Gentlemen in arrears since Midsummer are requested to forward their subscriptions during the present week.*

The MEDICAL TIMES is the only Medical Journal published at its own Office, and which is free from the control of all Booksellers and Publishers. Gentlemen may procure it by an order on any Newsman or Bookseller, or it will be sent direct from the Office of the Medical Times, *to Annual Subscribers, sending by a Post-office order, directed "James Angerstein Carfrae," or an order on some party in town, One Guinea IN ADVANCE, which will free them for twelve months. Half-Yearly Subscription, 13s.; Quarterly, 6s. 6d. No number of the* Medical Times *can be forwarded, except to gentlemen paying in advance.*

THE MEDICAL TIMES.

SATURDAY, AUGUST 8, 1846.

Justitiæ partes sunt non violare homines; verecundiæ non offendere.—CICERO.

IN concluding our comparison of professions, and of professional rewards and honours, we will take a passing glance at the bar.

Curran used to say that the first *desideratum* for a man's success at the bar, was to be not worth a shilling. His own career was an apt illustration of his saying; and in the career of many a man besides, equally distinguished with himself, it has been amply corroborated. Favouritism may have occasionally done an obscure man some service, in his commencement as a barrister; but this favouritism is only another name for the gracious act of giving intellect and industry an opportunity of developing themselves. No amount of personal or political trickery can give to a simple man the superiority over a wise one, when they compete together openly, and have public opinion for their judge. The truth of this observation is fully attested in the preference often obtained at the bar, by comparative indigence and obscurity, over wealth and patronage. This is the cardinal advantage that the three professions of arms, divinity, and law, have over ourselves—their deeds are public, and if meritorious, popular—we "do good by stealth," and are expected to blush if we find it fame. We get none of the credit that they get, whatever the excellence or success of our exertions.

It is hardly necessary that we should pause to inquire what amount of mental qualification a man needs, as a *sine qua non* to his promotion at the bar? Some men have shone very well, and gathered a goodly recompense, with a very average stock of this commodity: others, better supplied in the aforesaid sense, have proportionately advanced in fame and fortune. At any rate, we have no proof that a larger intellectual capacity is wanted for law than for physic; and very certain we are, that the attainments are neither more diversified nor more difficult, in the former than in the latter profession. Concerning the ultimate object of the two professions, the loftier is certainly on our own side. "All that a man hath will he give for his life," says the proverb; and every day's experience teaches us that worldly professions bear an inferior ratio to the desire of existence and health. To rescue a man from the grave, is certainly to render him a greater service than to save his estates from ruin; and to preserve the health and strength of a nation, is surely not inferior to administering laws for its good government. However the legal and medical professions may be viewed in comparison, we are assured that, in moral and intellectual dignity, and in public usefulness, our own ranks in nothing inferior.

Now, look at the relative advantages offered to the votaries of these two professions. If a man only have a tolerable start at the bar, and have anything more than an ordinary head to make it available, there is no saying where his preferment or perquisites may end. Besides that his immediate occupation furnishes for him emolument unparalleled, at least in physic, there are ultimate gains and gifts, in the possession of which the bar is singular. One man, in this lofty legal circle, pursues a career of lucrative practice for some years, and then, a commissionership, or other such bounty, falls in his way, and he has little to do, and is largely recompensed, all the rest of his days. Another man, after a probation perhaps not very protracted, during which he has been in the reverse of a starving position, finds the bench opens its affluent arms to receive him, and he cozily sits down, largely wigged and wealthy, for the remaining term of his natural life. A third, more ambitious, enterprising, and energetic, than the others, "flies at higher game," and seldom fails to reach it. He was distinguished, was this man, at college, for his literary acquirements and oratorical brilliancy. Whilst keeping "terms," his skill in debate, and his amount of legal knowledge, attracted attention towards him, and his *debut* at the bar was consequently made under the favourable auspices of ready-made reputation. Success attended his professional career, and it was not long before he was persuaded to contest a public election, the issue of which was to number him amongst the political representatives of the people. No sooner in the house, than he attracted its regard, and one ministerial change and another hurried him along the line of preferment, until he found his final status on the cushion of the Chancellor. This circuitous path, however, is not essential to the attainment, from the bar, of one of the highest dignities in the realm. A man's legal reputation may make it desirable that the government should select him for the office of Solicitor-General, into which he is first duly installed, and then, he is leisurely returned M.P. for some snug place that dare do none other than accept him. Once enstalled into this legislatorial office, pay, pension, and title are his peculiar privileges. A knighthood, a baronetcy, and the peerage, are the insignia of his success. If not "the father of a line of kings," he may become the father of a line of lords, and create a name and a character that will live till doomsday.

Now, in this distinction we see nothing unfair or improper; on the contrary, we think it a tribute due to talent, and the withholding of it we should call injustice. The surest way to procure intellect, is to promote the possessors of it. It is a purchaseable commodity, and is likely to be offered in the greatest plenty where it is most demanded, and the best price is given for it. No doubt the celebrity of the bar is maintained by the inducements which it affords to enterprising intelligence. Were those inducements to be withdrawn, the intellectual affluence of this community would sink with its grosser wealth, and the honour and fame that are now its boast would be lost to it for ever. It was nothing more than considering "the labourer worthy of his hire," when it was first projected to give to legal distinction title and fortune; and valuable though these are, they are not more than equivalent to the talent that inherits them.

Having freely accorded to the legal profession all the merit that is due to it, and grudged it none of its preferments and perquisites, we feel quite at liberty to ask why ourselves are shut out from every shadow of such advantages? Intellectually, morally, and in public usefulness, we are not an iota behind the bar, and yet how differently do we fare! Why should there be no elevated position, the creation of a just and generous government, for the enlightened and experienced of our profession to attain to, as the reward of industry, benevolence, and skill? Would it not be worthy of the elite amongst us, that in their latter days they should have honourable preferment equally with the pulpit and the bar? Does consummate skill in one of the noblest of professions; do years of gratuitous exercise of that skill upon the suffering poor; does the advancement of that generous science which teaches the relief and cure of disease; does a life of rectitude, and of incessant devotion to the interests of humanity, disentitle the author of these things to worldly distinction and fame? For ourselves, we should look upon deserts like these as the greatest claims that could be made

upon the generosity and gratitude of the world. And wherefore is the dutiful tribute withheld? Why, in this country at least, does not the representative power give honour where honour is due? We are not aware that the profession would be anything advantaged were a dozen of its greatest men to be selected for title, and placed on a bench in the House of Lords; and yet, we see no reason why the pulpit should send sundry of its members to this elevated quarter and ourselves send none. We are not aware that parson's heads are any better fitted for legislating than our own would be, were we afforded the opportunity of exercising them. At any rate we see a gross injustice in shutting us out from title and emolument when the clergy have these things so open to them. And the same may we say of the bar. In the walks of legislation we have no desire to be their rivals; but these said walks are the recompense of talent and industry. And why, again we ask, is there no like *ultimatum* for us? Anywhere but in England the medical profession is judged of in proportion to its merits, and rewarded accordingly. But here, in the face of boasted liberality, and encouragement of literature and science, we get no quarter. In France, the physician and surgeon are appreciated as they deserve, and are not denied the honours to which other professions attain. They are decorated with some of the choicest insignia of the realm, and are admitted without scruple to the dignities of the peerage! This is generosity and justice in happy companionship. And who will say that France does not reflect honour upon herself in this virtuous judgment? And when may we hope that England will do itself the credit of imitating so lofty an example? When may we hope to see the mean, offensive old prejudices swept from the minds of our senators, and their hearts opened to reward and dignify the deserving? We should particularly like to know why a peerage is closed against us, when it receives members of other professions without scruple? We are aware that there must be some drawback, but we have never yet been able to learn what it is. In none of these qualities that adorn mankind, can we find ourselves one jot or tittle inferior to others more favoured than we are, and hence our cry—wherefore the injustice? We shall feel deeply gratified if any one, having authority, will solve a problem that has so long puzzled us. George the Fourth, we know, was a great admirer and friend of Sir Henry Halford, and, it was said, desired to have him raised to the peerage, but all to no purpose. The man who was physician to four sovereigns, a distinction unparallelled, enjoyed a baronetcy in common with many a retired linendraper, cheesemonger, or tallow-chandler, but nothing beyond, save two little, almost nameless, distinctions, given by the last William and George. Whilst their contemporaries, on the continent, were in the enjoyment of the titles of nobility—a title, the noblest, when worn by those who have earned it, Baillie, Halford, Cooper, Abernethy, and others of their order, in generous England, gained the distinction of retired tradesmen—*and nothing more!* Oh! how pitifully, contemptibly mean does our country's character look, when, with all its boasted enlightenment and love of learning and science, and its patronizing propensities forsooth, it is on these very counts weighed in the scale against other nations and found wanting! We can only blush for its faults, and pray Providence to hasten their amendment. We have been prompted to the utterance of these unpalatable truths from a stern sense of the injustice under which, as a profession, we labour. Our heart's desire is, that those who are in high places may be speedily disposed to render us the recompense that is our due.

Quum tua pervideas oculis mala lippus inunctis,
Cur in amicorum vitiis tam cernis acutum,
Quam aut aquila, aut serpens Epidaurius? At tibi contra
Evenit, inquirant vitia ut tua rursus et illi.   HORACE.

The Council of our English College of Surgeons have so habituated us to follies, perpetrated on the largest scale, as to have spoiled our relish for any ordinary piece of turpitude or blundering. Our editorial tablets hold against them this week, the tale of a small wrong, mischievous, *directly*, to no more than an individual, but in asking attention to it we feel like the barrister, who, after convicting a prisoner of some half dozen capital felonies, puts the wretch under trial for a petty larceny. Yet, in our case, the labour is perhaps not all lost. If the criminals be past punishment as past recovery, it is something still to do justice to their innocent victim. Let us briefly tell our tale therefore.

The appointment, some years since, of three studentships in comparative anatomy, with a salary of one hundred pounds a year each, has been, as our readers know, the only decent thing done by the Council during the last decade of their deplorable reign. It was the one solitary fact that indicated a knowledge that there existed such a thing as "public" and was such an idea as a "duty." As might be expected, the deviation has been matter of repentance ever since. It was an anomaly not to be forgiven even to themselves; like a dove in a rookery, it was a *rara avis* to be pecked out of place and plumage the first opportunity. Since that unfortunate day of partial goodness, therefore, the great policy of these large-minded men has been to retrograde practically whence, in a moment of weakness, they advanced speculatively. True, to their system of the worst possible mismanagement, they have been superlatively active in making their one boon inoperative.

Two years since, one of these studentships (cut down from three to two!) was obtained, after the usual competition, by a clever young man, Mr. Pittard, recently a student of King's College. For months his good fortune set the Council's ingenuity at defiance; but, unfortunately, as an evil fate would have it, in June last, the managers of the Aldersgate medical school, did the college the honour of asking its pupil, Mr. Pittard, to take the situation of its summer lecturer on comparative anatomy; an office that might be discharged in over hours, and which, in every sense, was a post the reverse of incompatible with the duties of his studentship. The college patronage had won its legitimate consequence; its prize had at once attracted and rewarded merit; its liberality had opened to a worthy young man a high career of science. So much the worse for Mr. Pittard, and so much the greater reason for collegiate interposision and collegiate obstruction. The boon was doing, alas! but too much good without such an unexpected contingency. The Council met in haste—a general indignation was felt at so insulting an amount of deserved success. Without more ado than hearing the "*report*" that there was such a lectorship, they suspended Mr. Pittard from his studentship! They asked no explanation from their too fortunate *protege*; they content themselves with a verbal announcement, through one of their servants, that Mr. Pittard was suspended "till an enquiry should be made."

Castigatque, auditque.

They punish first to make sure; and then "*enquire*" whether there were grounds! Any thing to avenge the scientific successes of a *too* scientific pupil!

This wrong differs from most others in this:—that not even the fragment of a case can be set up for it. Radamanthus like, they punish on a rumour which is not matter of *belief* but of "*enquiry*." Then, the "rumour" implies no charge that Mr. Pittard abstracts any time from the College which the college can claim from him, or that the over time given to other labours is given to any thing not akin to the duties of his studentship. On the contrary, the discharge of his collegiate duties stands unimpeached, and his other labours have a direct bearing on the science the college affects; to encourage. Finally, what Mr. Pittard has done has been done, unreproved, by those who have preceded him in the same office; and consistently to condemn his conduct the Council must first perpetrate the outrage of censuring a Quekett and an Owen for their extra-collegiate contributions to sanatory and scientific improvement. The injustice, we own, is intrinsically small, and affects but one individual, but the Council, with their customary fatality, have contrived to throw about it every possible adjunct of mis-doing. They touch nothing but to deform it—to deform it in excess! But we have already said too much, on this small matter, of a body whom to mention on any matter is to condemn. Our readers will pardon us the needless inculpation, and overlook our brief trespass on an attention palled by larger by the reflection that if on one side we cannot make black blacker, it is something on the other to keep white undarkened by the contact.

THE CHOLERA.

It is our pleasing duty to state that the official statements of the existence of Asiatic cholera in the metropolis are wholly unfounded in fact. Some cases of diarrhœa and dysentery have occurred in about the proportion we might have expected from the excessive heat of the season; but, as yet, no instance of the much dreaded visitor has made its appearance. The civic proclamation which recently alarmed the public

arose from some hasty mistake of a functionary long known about the corporation precincts as the "Columbus of mare's nests"—we mean Sir Peter Laurie.

INQUEST AT HOUNSLOW.

We have much more to say on this interesting subject. If the coroner's inquisition be not quashed by law, it shall receive the equivalent justice from the public, and be valued at its worth. We give as data for further comment, the medical evidence of Monday last, as given us though the (in *this* case) very partial report of *The Times.*

The depositions of the medical witnesses were here read to them.

Mr. Day made a complaint that Mr. Wilson had, *in addition to the statements they had agreed on making at the post mortem examination, given in evidence opinions which he (Mr. Day) had not acceded to,* and from which he dissented. He did not consider that inflammation of the pleura could be caused by the muscular disorganization observed, for that was covered by the intercostal muscles.

The Coroner.—*But is it not a fact, Mr. Day, that a formation of mattery substance connected with the veins of the skin is often the cause of inflammation of the lungs.*

Mr. Day.—Yes it is so; but I do not think that in the case of the deceased, the muscular disorganization was the cause of death.

When the reading of the depositions was concluded, *the medical gentlemen were ordered to leave the room, and each was summoned in separately* in the order in which he had given his evidence, to say what, in his opinion, after having heard all the evidence in the case, had been the cause of the deceased's death.

Dr. Warren.—The first in order who entered the room, repeated his former statement, that White had died of inflammation of the pleura and heart, with its connecting vessels, and that the flogging had in no way caused his death. The deceased was not depressed in spirits, for had he been so, he (Dr. Warren,) who visited the hospital twice every day, must have noticed the fact.

The Coroner.—It is your belief that if he had not been flogged, he would have been alive now?

Dr. Warren.—That is a question which no human being can answer; and the man who ventures to do so puts a great deal at stake.

The Coroner.—You cannot fail to bear in mind that on you devolved the duty of examining the deceased on the day he was tried, and again on that of his punishment. The jury will, therefore, infer that you satisfied yourself he was a sound man.

Dr. Warren.—I find, that in the admission and discharge-book, he has been only three times in hospital for six years. Had I found him faint during the flogging, I would have ordered him to be taken down. I admit that an intermitting pulse shows a greater state of danger than even fainting; but I have no instructions on such occasions as to how I am to discharge my duty—(A pause here, followed, after which Dr. Warren, with a degree of feeling which excited marks of applause in court, said)—I beg to say that it is to me a most painful duty to witness such an operation, and I should be most happy to think that I should never be called upon again to witness so disgusting a scene.

Dr. Hall, the next medical gentleman admitted, said,—after hearing the evidence, I am still of opinion that the deceased died from inflammation of the heart, lungs, and pleura, and notwithstanding the evidence of Mathewson and Reilly, cannot connect the disease with the punishment, or subscribe to the novel doctrine of Mr. Wilson. He does not ascribe this changed condition of the deep-seated muscles to the violence of the lash, as they were protected from that by their position, and by the superjacent parts, but to excessive contraction during the agony of punishment, and subsequent disorganizing inflammation from nervous depression. Now, White was in the prime of life, and does not appear, by the statements we have just heard read, to have suffered much from nervous depression. It is strange, therefore, and unaccountable to me, why nature should have made no efforts to repair this injury, or that her efforts should have been of a disorganizing kind in this particular spot, while the process of healthy reparation was proceeding rapidly in other parts of his frame. The injury itself, too, is one of a novel kind, and difficult to reconcile to our preconceived opinions of the limited power and action of the small muscles alluded to. White, the witnesses all say, bore his punishment without any struggling; and Dr. Warren says he observed no spasmodic action of the muscles of the spine. Besides, had Mr. Wilson ever witnessed the infliction of corporal punishment he would have seen that it is the superficial layers of muscles which attach the shoulder-blades to the spine that are thrown in action, and had any rupture of muscular fibre taken place from violent contraction, it would most likely have occurred amongst those, and not among the deeper-seated ones along the spine, which have such limited contractile power, and are so well protected from injury. Mr. Wilson lays much stress on the injurious effects likely to have been produced by this altered portion of muscular fibre lying in contact with the intercostal spaces; but it seems to have escaped his recollection that the cavity of the chest on that side was filled with diseased and disorganized viscera, and highly putrid, fluids, which were much more likely to have contaminated the adjacent muscles, than that the small portion of pulpy fibre should have occasioned the extensive disease that was discovered within the chest. The only wonder is, after 11 day's exposure of the body, at this hot season of the year, that the change of structure was not still more extensive. Mr. Wilson states that he has dissected from 500 to 1,000 bodies in the course of his professional researches. I have also served much in warm climates, where deaths unfortunately are very common, and decomposition of the body after death very rapid, and I should say from Mr. Wilson's description that the change he observed was merely the first stage of putrefaction.

The Coroner.—Is it not the limited powers of contraction in the muscles which Mr. Wilson refers to which makes them subject to injury?

Dr. Hall.—I should say that the change observed by him was the first stage of putrefaction. I regret that I was excluded from the subsequent *post mortem* examination, and I enter my protest against that exclusion.

The Coroner.—Will you state what right you had to be present more than any other person?

Dr. Hall.—I think it was only fair from the particular turn which public opinion had taken on the subject that I should be present.

The Coroner.—In point of fact, the irregularities which have preceded have brought us into many difficulties.

Dr. Hall.—I don't admit that those proceedings were irregular, because, in point of fact, it was a public examination.

The Coroner.—How happens it that you were sent for at all, Dr. Hall? What were the special circumstances which led to that? Do you not believe that it was in consequence of the deceased dying so soon after being flogged?

Dr. Hall.—I was sent to make the *post-mortem* examination in consequence of the report I had previously made about White to Sir James M'Gregor.

The Coroner.—In your report, you say, it appears, White received corporal punishment of 150 lashes.—Why did you mention that fact, if you did not connect it with his illness?

Dr. Hall.—I was bound to say all I knew, and I considered it important to state that fact.

The Coroner.—It would have relieved us of a great deal of difficulty if notice had been given at once to the constable, and an inquest had been constituted on the first *post-mortem* examination. You have made your report, and sent in your opinion, and now you complain that you were not present at an examination made by a surgeon who came before the court as an unbiassed person. You yourself have in your report connected the flogging with the death of the deceased.

Dr. Hall.—The connexion exists, but it is not one of cause and effect.

The Coroner.—Could you form any idea as to the state of deceased's mind from the *post-mortem* examination?

Dr. Hall.—No, I could not; the appearances of disease in the brain were not sufficiently decided for that; but they looked as if the deceased had had delirium tremens. Dr. Hall concluded by repeating his belief that the death of White was to be accounted for by the sudden change of temperature on the 5th and 6th of July, amounting to a difference of more than twenty degrees.

The Coroner drew Dr. Hall's attention more than once to the expression used in his report, that the circumstances of the case were peculiarly interesting.

Dr. Reid and Mr. Day repeated their belief, expressed in evidence on a previous day, that the deceased had died from inflammation of the heart, lungs, and pleura, brought on by atmospheric changes, and having nothing to do with the punishment inflicted on him.

The punishment might have had some effect in producing the disease.

The Coroner here asked Dr. Hall if he considered the letter, dated the 25th of June, written by deceased to his brother, to be the letter of a man in cheerful spirits?

Dr. Hall replied that there appeared only one passage in this letter which could indicate to the contrary, and, in opposition to the conclusion to be drawn from this, he set the statements of all the witnesses, that White had not been, and had not appeared, depressed in spirits.

Mr. Wilson was then called.

The Coroner put the question:—After hearing the depositions, what do you consider was the cause, of the deceased, White's, death. No question of it, the flogging, and its consequences upon his health. The inducement to me to form that opinion is, that death from flogging is of no uncommon occurrence. The diseases following upon flogging in general are identical with those which manifested themselves in the case of White. I hold in my hand some abstract cases of flogging, these will prove that my opinions are confirmed by the greatest men in the country.

Dr. Hall was here addressed by the coroner, and was asked if he had any opposing authorities to refer to. He had not. He had seen several hundreds of cases of flogging, and death ensued in one case only out of every thousand.

Mr. Wilson resumed.—Extensive injuries to the skin will produce serious internal irritation. Thus a burn will give rise to fatal disease of the internal organs, viz., stomach and bowels, heart and lungs, liver and kidneys, so that prolonged irritation of the skin in this case was calculated to produce disease. Then there might have been secondary disease, inflammation of the heart, and lungs, weeks after the application of the cause of the original disease. Such cases are frequently to be met with in our hospitals; so that, whether I look at the primary or secondary effects of flogging, I see in both a cause of fatal disease. Heretofore it has been considered that the injuries resulting from flogging are confined to the skin, but I have given evidence that, in this case, the flogging was followed by a pulpy, softening and deranged state of the muscles.

The Coroner.—You will remember that there was in this case a partial recovery.

Mr. Wilson.—It is not an uncommon thing that when, after flogging, the patient is pronounced to be, and thinks himself to be, out of all danger, internal inflammation then commences, and that results in death.

The Coroner.—Leaving out of the question mere speculations, is it your decided opinion, from all you have heard of the history of the case, that the death of White was caused by flogging?—I have not the slightest doubt that it was.

The Coroner.—After deliberating upon all the

facts heard in evidence or observed by yourself, and deliberating upon them as cautiously as you can, do you entertain a doubt on the subject? for if you do, it is your bounden duty to state it.—I have not the slightest doubt on the subject.

Some conversation having ensued between the coroner and Mr. Wilson, touching the contradiction which Mr. Day had offered to the testimony of the latter.

The Coroner said, you have opened from 500 to 1,000 bodies, and in cases of these examinations, did you find such a state of the muscles as that perceived in the case of White to result from decomposition?—No, in no one case.

The Coroner addressed the jury:—The inquest had been called, not because there had been a sudden death, or because there had been a suspicion of poison; the warrant had been demanded on the undisguised suspicion that White had lost his life solely in consequence of the violence of the punishment. The two staff-surgeons having made their examination, and reported their opinions that the death resulted from natural causes, it became necessary for him to intimate to the jury to name their own surgeon, to complete what had been only a partial examination. Mr. Day had been named. Mr. Day, however, himself made but a partial examination, and then confirmed the already-expressed opinions. It had been thought necessary by the jury that a gentleman should be called from London, and that the body, now buried some days, should be by him examined. *He had not hesitated in looking for the most competent person to fix on*—Mr. Erasmus Wilson. It was right he should say that Mr. Wilson was a gentleman of distinguished acquirements in his profession, a first-rate anatomist, and a gentleman with a high character for unimpeachable veracity. The jury, therefore, had to choose their own authority, to select between Mr. Wilson and the three others, also eminent medical gentlemen.

The jury returned with the following verdict:—"That the deceased soldier, Frederick John White, died on the 11 of June, 1846, from the mortal effects of a severe and cruel flogging of 150 lashes, which he received on the 15th of June 1846, at the Cavalry Barracks, on Hounslow Heath, at Heston; that the said flogging was inflicted upon his back and neck, under the sentence of a district Court-martial composed of officers of the 7th. Regiment of Hussars, held on the 10th of June previous, duly constituted for his trial. That the said Court-martial was authorized by law to pass the said severe and cruel sentence; that the flogging was inflicted upon him by two farriers in the presence of John James Whyte, the Lieutenant-Colonel, and James Low Warren, the Surgeon of the said Regiment; and that so, and by means of the said flogging, the death of the said Frederick John White was caused. In returning this verdict, the jury cannot refrain from expressing their horror and disgust at the existence of any law amongst the statutes or regulations of this realm, which permits the revolting punishment of flogging to be inflicted upon British soldiers; and at the same time the jury implore every man in this kingdom to join hand and heart in forwarding petitions to the Legislature, praying in the most urgent terms for the abolitino of every law, order, and regulation which permits the disgraceful practice of flogging to remain one moment longer a stain upon the humanity and fair name of the people of this country."

Miscellaneous Correspondence.

TEETOTALISM A CAUSE OF ACNE.

3, Finsbury Place, South. August 5th, 1846.

[To the Editor of the "Medical Times."]

Sir,—On the principle of the well known motto "*Audi alteram partem*," a principle fully recognized in your highly valued columns, I must ask for the insertion of a few lines in reply to Mr. Fothergill's comments on my opinion, that *Teetotalism* predisposes to Acne. I may in the first place remark that although not a Teetotaler myself, *no advocate of Temperance, however strict, can view with greater repugnance than myself, the vicious habit of excessive, or intemperate indulgence in inebriating drinks*; and that I am so conscious of their noxious tendency in diseases of the skin, (acne included) that few patients come before me, to whom I do not strenuously inculcate the Shakespearian lesson; not—

"To put an enemy in their mouth, to steal away their brains."

With regard however, to the usefulness of a moderate proportion of Alcohol in the dietetic treatment of Acne, I can assure your correspondent that I have daily opportunities of witnessing facts corroborative of this "fancy" of mine, and indicating very clearly that Teetotalism and acne stand in this relation at times of cause and effect. As an exemplification, I beg to subjoin a tabular arrangement of every case of acne, presenting itself at the Cutaneous Institution on Monday and Wednesday last. These memoranda, made in consequence of Mr. F's letter, were taken in the presence of a medical Practitioner (Mr. D. Davies) who is a student at the Institution. The leading questions biased the replies of the patient, which are given as they occurred and in the order of the individual's attendance.

CASE 1.—James Walker, aged 20, of 12, Pitfield-street, Hoxton, Reg. No. 8369.

Form.—Acne simplex et Rosacea, very severe case, 18 months duration, now convalescent.

Habit.—Never drinks beer or spirits at all "a Teetotaler from taste."

CASE 2.—Hester Clements, aged 32, of 10, Brewer-street, Golden-sqr. Reg. 7124.

Form.—Acne Rosacea, severe case of five years standing, now convalescent.

Habit.—Formerly drank beer, but five years ago on account of illness was advised to discontinue it, the eruption has since appeared, now drinks water, or a little spirit and water.

CASE 3.—Fanny Fryer, aged 36, of Brunswick Terrace, City Road, Reg. 8662.

Form.—Acne Rosacea of Acne indurata, of seven years duration, nearly well.

Habit.—Drinks a little beer with dinner, left it off for five months by medical advice when the complaint became much worse—"face not fit to b seen,"—now better.

CASE 4.—Mary Tibbs, aged 22, 15, Thomas-street, Bethnal-green; second application to the Institution. Reg. 9059.

Form.—Acne Pustulosa, "two years duration; applied some months ago, and got well; re-appeared this hot weather." Eruption very slight.

Habit.—Drinks quarter of a pint of beer per day. "No spirits."

CASE 5.—Mary Conder, aged 22, of No. 4, Lees buildings, Fetter-lane. Reg. 9063.

Form.—Acne Simplex indurata; rather severe case; some years duration.

Habit.—"Very poor; does not drink a pint of beer a week;" "can't get it."

CASE. 6.—Jane Enderson, aged 21, No. 8, Church-street, Blackfriars-road. Reg. 8868.

Form.—Acne Simplex inveterata, two years duration. Improving.

Habit.—"Drinks half a pint of beer twice a day. Married and suckling, and cannot do without it."

CASE 7.—George Cane, aged 16, of 43, Kingsland-road. Registered.

Form.—Acne Punctata. Two years duration.

Habit.—"Takes a pint of beer daily; ordered to discontinue by me. Rather worse since."

CASE 8.—James Charles, aged 28, Churchway-street, St. Pancras. Reg. 8671.

Form.—Acne Rosacea inveterata of seven years standing. Very severe case, so as to prevent his obtaining employment.

Habit.—Habitually drank two pints of beer daily since attendance here. Has taken two glasses of warm gin and water per day, and is now well.

CASE 9.—Harriet Pritchard, aged 34, No. 3, Kent-place. Reg. 8028.

Form.—Acne Rosacea; seven years duration; severe. This day discharged, cured.

Habit.—"Does not like beer; half a pint will serve three days, but has taken more lately instead of gin and water, as advised. Formerly drank *vin ordinaire* freely, when residing in France."

CASE 10.—Elizabeth Trevener, aged 34, of No. 5, Queen's-terrace. Reg. 8125.

Form.—Acne Indurata et Rosacea of ten years standing.

Habit.—"Used to drink beer; then left it off; became worse; now drinks gin and water, and is getting well."

CASE 11.—Anna Armes, aged 22, 5, New-road, Sloane-street. Reg. 8388.

Form.—Acne Punctata; four years.

Habit.—Never drinks beer; only tea and coffee; has lately taken gin and water, and this day is discharged, cured.

CASE 12.—Adelaide Benjamin, aged 23, No. 163, White Cross-street. Reg. 8790.

Form.—Acne Indurata et Rosacea; two years standing; now convalescent.

Habit.—"About a pint of beer a week is as much as she ever takes; as she does not take it now, drinks gin and water."

CASE 13.—Caroline Short, aged 22, of 87, Hare-street. Reg. 8852.

Form.—Acne Punctata et Rosacea; one year standing, but now well.

Habit.—"Has drunk one pint of beer daily."

The above thirteen cases, it is believed, will speak for themselves, as regards the point under discussion; and, perchance, demonstrate that in acneous disorders "a little wine for the stomach's sake" may be found useful.

I am, dear Sir,
Your faithful servant,
JAMES STARTIN.

PHYSICIANS AND GENERAL PRACTITIONERS.

[To the Editor of the Medical Times.]

SIR,—Poor Dr. David Bell has received so severe a castigation, at the hands of your correspondent "Crito," in the last week's *Medical Times*, that I ought not in mercy to add to his torture; but I cannot refrain from making an additional remark or two.

The doctor is evidently upon the wrong tack—for he insists that the acquirement of the physician, both general and special, *ought* to be greater than those of the general practitioner—and he would bring about this state of things—not by elevating the standard of the physician's education, but by depressing that of the general practitioner. Now, there's the rub—the education of the general practitioner of late years has progressed in a higher proportion than that of the physicians, consequently consulting practice is at a tremendous discount.

The doctor is aware of this fact, and therefore discountenances the use of the university degree of Doctor of Medicine—and its title, if obtained by a general practitioner—as if the *only distinction* between the two grades of practitioners resided in the empty title.

It appears to me, Sir, that any one who ever obtains a degree has a right to the title of it—whatever may be his mode of practice—and whether he practise his profession, or not. In fact you cannot deprive him of it—do what you will. A doctor is a doctor, whether he be M.D., D.D., L.L.D., D.C.H., or Ph.D., and it would be as erroneous to call a man possessing either of these degrees *Mr.*, as it would be to apply the prefix *Dr.* to a man having no degree at all.

The physician complains that the use of the title, five general practitioners out of six possessing the Doctorate, does away with the only public distinction between the pure physician and the man in general practice; the consulting surgeon would have the same reason to complain of the use of the term "Surgeon," by the general practitioner; but the mode of practice of each grade is known in each locality, and that is sufficient.

The doctor dabs on a little "soft soap," and shows a desire to keep in with the few general practitioners who may occasionally call him in—but throughout his letter there is an appearance

of antipathy to the class—very evident to the most superficial observer. His jeering at the Apothecaries' Company and the national Association comes with very bad grace at this particular crisis—and shows the animus which dictated the first attempt at medical legislation some two years ago.

It is but too evident that the general practitioners must look after themselves, and the only practicable mode is the establishment of the National Institute. The eyes of the medical world are directed with intense interest upon the important proceedings of the next week,—a combination of zeal, unanimity and prudence on the part of the first officers of the new Institute will place the entire class of general practitioners in an unprecedented position of importance and influence. I am Sir, your most obedient Servant

August. 5th. 1846. CHIRURGUS.

EXAMINATION OF THE UNIVERSITY OF LONDON.

(M.B.—FIRST EXAMINATION.)

Monday, August 3rd, Morning 10 to 1.

ANATOMY AND PHYSIOLOGY. — *Examiners* Mr. KIERNAN and Professor SHARPEY.—1. Describe that portion of the side and basis of the skull, which is bounded in front by the orbital process of the frontal bone and by the posterior surface of the malar bone; behind by a vertical line passing behind the mastoid process to the posterior part of the condyle of the occipital superiorly by a horizontal line passing over the squamous suture, and internally by the mesial line. Commence the description at the upper limit, and mention the parts in the order in which they are seen in proceeding towards the mesial line.

2. Give an account of the articulations of the scapula with the clavicle and humerus, describing the articular surfaces, the ligaments, the synovial membranes and the articular cartilages, and the proper ligaments of the Scapula. Describe the movements which take place in these joints, and also those of the sterno-clavicular articulation, mentioning the muscles by which they are severally effected.

3. Give the anatomy of the rectum; describing the structure, form and situation of the intestine, its blood-vessels and nerves, and its relations to the peritoneum and to other adjacent parts of the two sexes.

4. Give an account of the popliteal region, describing its form and boundaries, and the parts contained in it, commencing the dissection at the skin and carrying it to the bones.

5. Commencing at the integuments state the dissection required to show the course of the Radial Artery from its origin at the bend of the elbow to the termination of the deep palmar arch. Describe the relations of the artery to other structures in the different parts of its course and mention the branches in the order in which they arise, but describing the course of those branches only which are necessarily seen in the steps of the dissection required to expose the main artery.

Afternoon, 3 to 6.

1. Describe the intrinsic muscles of the larynx, mentioning their actions and explaining the chief uses to which they are subservient. Describe also the distribution of the Laryngeal nerves, and state what are believed to be their respective functions.

2. Describe the parts met with in d[illegible]ing the branches of the portio dura of the seventh pair of nerves after they have emerged from the parotid gland.

3. State the dissection required [illegible] the interior of the abdomen the course of [illegible] epigastric artery, the former from its origin to its entrance into the crural or foramen, the [illegible] as far as the point where it becomes concealed by the sheath of the rectus muscle. Describe the parts brought into view in the dissection, the chief variations to which the vessels in question are subject, and the relations of these vessels to the inguinal and crural apertures.

4. Give a description of the dura mater; including its intimate structure, its extent and connexions in the cranium and vertebral canal, its relations to the cranial and spinal nerves, the arteries which supply the membrane with blood, and the venous sinuses contained in it.

5. Describe the structure and connexions of the tongue, and the blood-vessels and nerves distributed to it. Enumerate its principal movements and the muscles producing them, and state what are the most probable functions of its different nerves.

6. Give an account of the system of lymphatic vessels, describing their structure, and that of a lymphatic vessel, their mode of origin, general course and termination.

Tuesday, August 4, Morning 10 to 1.

CHEMISTRY.—*Examiner* Professor BRANDE.—1. What are the general effects of heat upon the different forms of matter? how are these effects theoretically explained? What are their principal influences in nature? State the different ways in which heat is propagated through solid, liquid and aeriform bodies.

2. A spring water contains free carbonic acid carbonate and sulphate of lime, chloride of sodium and carbonate of soda. How would you ascertain the presence of these substances and determine their respective quantities?

3. What is the atomic constitution of alcohol and of ether? How is ether usually obtained and what are the phenomena attendant upon its production?

4. In the analysis of an alloy of equal parts of lead, tin, bismuth, and copper, how would you separate the component metals and determine their respective quantities?

5. What are the leading proximate constituents of the blood? how are they chemically distinguished and separately obtained?

6. The bottles marked A and B contain saline solutions; they are accompanied by appropriate tests by which their respective bases and acids may be recognised; you are requested to name these, and to write their respective symbols and equivalents.

Afternoon 3 to 6.

MATERIA MEDICA AND PHARMACY.—*Examiner*, Dr. PEREIRA. — 1. Describe the *Papaver somniferum* botanically, the method of preparing Opium, and the process given in the London Pharmacopœia for the preparation of *Morphiæ Hydrochloras*. Enumerate the peculiar proximate principles which have been obtained from Opium; and mention the chemical characters by which Morphia, Narcotina, and Meconic Acid are respectively distinguished. State the indications, and contra-indications for the use of Opium, and the dose of this drug, as well as of Morphia.

2. Describe the method of preparing *Vinum Colchici*, the properties and composition of antimonial wine, the changes which it undergoes by exposure to the air, and its dose and uses.

3. How are the presence of nitric acid in acetic acid; of iron in sulphate of copper, and of carbonate of potash in iodide of potassium to be respectively ascertained?

4. Enumerate the most important officinal narcotics and explain their respective peculiarities of operation.

5. What are the doses of Strychnia, Veratria, Conium, Biniodide of Mercury, and Iodide of Lead?

BOTANY.—*Examiner*, Rev. Professor HENSLOW.—1. Define, and give examples [illegible] the [illegible] [illegible] the following terms:—Amentum — Corymbus — Hypanthium — Pedunculus — [illegible] — Vitta.

2. Give diagnoses of the following Orders:—[illegible] — Solanaceæ — Colchicaceæ.

3. What are the more important characters in the following genera:—Papaver, Centaurea, Polemonium; Crocus? Describe particularly the characters of the several floral whorls, fruit, seed, vernation and æstivation.

GOSSIP OF THE WEEK.

APOTHECARIES' HALL, July 29th.—John Renwick, George Charles Stacpoole, John Charles Collins, George Henry Jenkins.

THE QUEEN'S COLLEGE AT BIRMINGHAM.—The Queen has been graciously pleased to issue her Majesty's warrant, under the sign manual, "to authorise the right trusty and well-beloved the Principal, and the trusty and well-beloved the Vice-Principal, of Queen's College at Birmingham, to issue to such persons as may be desirous of becoming candidates for the respective degrees of Bachelor of Arts, Master of Arts, Bachelor of Laws, or Doctor of Laws, to be conferred by the University of London, certificates to the effect that such candidates have completed the course of instruction which the Chancellor, Vice-Chancellor, and Fellows of the said University of London, by regulation in that behalf, shall have determined." The Council of the college, at their last monthly board, have unanimously elected the Rev. G. Richards, B.A., Pembroke College, Oxon., resident Classical Tutor and Chaplain of the college; the Rev. J. Taylor, B.A., St. John's Coll., Cantab., resident Mathematical Tutor and Chaplain of the College Hospital; Herr J. Mayland, German Master; Jean J. O Flannagan, French Master; and Chas. Docher, Esq., Drawing Master. The first and second years' students in the Classical Department will reside with the Rev. J. O. Welstead, after which they will reside in college to complete their medical studies.

ROYAL COLLEGE OF SURGEONS, *July 31st.*—Gentlemen admitted members: Messrs. C. H. Hallett, T. Webster, E. S. Guest, R. T. Martland, J. E. Scott, and J. G. Pasquin. *Aug. 3rd.*—Messrs. P. E. Meggs, H. Cresswell, J. Goodchild, J. Williams, H. Wellings, S. L. Gill, W. T. Cleveland, T. J. Barnes, R. W. Baxter, W. J. Kite, and T. Hopgood.

OBITUARY. At Carlisle, on the 18th ult., aged 41, Richard James, Esq., M.D., second son of the late John James, Esq., surgeon. At Stockton-on-Tees, on the 19th ult., Mr. William Milburn, surgeon. At his residence, King's-square, Bristol, on the 21st ult., James Frowse, Esq., surgeon, aged 54.

The Chemist Rowe, who was indicted for the manslaughter of Elizabeth Munro a short time since at Plymouth, has been tried at the recent assizes at Exeter and acquitted. The particulars of the case will be found in a recent number of the *Medical Times*. No new facts appeared on the trial.

MORTALITY TABLE.

For the Week ending Saturday, August. 1, 1846.

Causes of Death.	Total.	Average of 5 summers.	Average of 5 years
ALL CAUSES	1086		968
SPECIFIED CAUSES	1083	892	961
Zymotic (or Epidemic, Endemic, and Contagious) Diseases	329	201	
SPORADIC DISEASES—

PROGRESS OF MEDICAL SCIENCE,

INCLUDING CHEMISTRY AND PHARMACY.

France.

[From our own Correspondent.]

ACADEMY OF SCIENCES.

Meetings of July 27, and August 3, 1846; M. BRONGNIART, V.P., in the Chair.

PRESENCE OF SUGAR IN THE BLOOD.—M. Magendie read a paper in which he endeavoured to prove that free sugar is contained in the blood. The method adopted by the learned physiologist for the demonstration of its presence consisted in the introduction of *starch* into the circulation. The facility with which this substance is changed into sugar must still leave the question in doubt, in spite of the assertions of the professor.

DIGESTION AND ASSIMILATION OF ALBUMINOID SUBSTANCES; by M. Mialhe.—It is only within a very few years that the gastric juice has been the object of experimental inquiry, and its precise function is not yet positively ascertained. Many still adopting Vanhelmont's theory of fermentation, still believe the gastric juice to be a universal solvent, whilst others deprive it, on the contrary, of all fluidifying power. The gastric juice is composed of two chemical elements: one is acid, the other a ferment. According to Berzelius, the acid portion is formed by a mixture of all the acids of the salts which have been detected in the juice. In the ferment four principles exist: pepsin, chymosin, gasterasis, and diastasis. The three first form only one substance; their chemical properties are the same; they should be confounded under one denomination—pepsin. This substance coagulates milk, fibrin, and gluten, but never exercises any saccharifying power on starch. This is its great difference from diastasis.

M. Mialhe proposes the following theory for the purpose of explaining the formation of chyme:—the acids produce a coagulum of a whitish colour on the surface of the alimentary bolus; and this coagulum the pepsin dissolves, and renders fit for assimilation. Thus, the stomach is not only a passage, but an organ of elaboration, in which the transformation into chyme is performed.

All albuminous substances, without any exception, are changed by pepsin into a compound always identical to itself, which M. Mialhe calls albuminosis. This body is solid, white, soluble in water, but not in spirit: heat, acids, alcalies, or pepsin produce no precipitate in its solution, but a deposit is caused by the addition of many metallic salts. Alone albuminosis is susceptible of assimilation; pure albumen introduced into the veins passes unaltered through the kidneys; and fibrin, when not modified by pepsin, causes instantaneous death from obstruction of the pulmonary circulation.

COFFEE; by M. Payen.—We forwarded on a former occasion to the readers of the *Medical Times* an account of M. Payen's first researches on coffee. This distinguished chemist guided entirely by theoretical views, and finding in coffee a large amount of nitrogen, boldly pronounced that fluid to be endowed with highly nutritive properties. The learned writer had perhaps not sufficiently considered the physiological part of the subject. It does not seem to us that the single fact of the presence of nitrogen is sufficient to render any substance nutritious; the nitrogen must also be endowed with the power of being assimilable to the system, else urea, hartshorn, and prussic acid, which contain a much larger proportion of azote than coffee, would be still more nutritious articles of food, an opinion which even M. Payen would not be disposed to admit without some reserve.

In his second communication, M. Payen states that he has detected in coffee a new crystallisable acid, and a double salt. The acid he calls *chloroginic*. Its composition is the following:—carbon 56, hydrogen 5 6, and oxygen 38 4.

By the combination of this acid with potass and cafeine a double salt is produced, it boils at 185° cent., and is decomposed by a heat of 230°. The composition of the salt is, acid 64, potass 8, cafeine 30. Cafeine is formed of C^{16}, H^{10}, Az, $O3$, As to the aroma of the liquid, it appears to be due to two essential oils contained in the coffee and liberated by mild torrefaction.

ACADEMY OF MEDICINE.

Meeting of August 4, 1846; M. ROCHE in the Chair.

THE PLAGUE.

The debate on this interminable question still continues at the Academy. No new facts, however, were brought forward in the long speeches of Prof. Adelon or M. Rochoux, nor in the answers of M. Prus. The debate was adjourned to the next meeting.

THE SPAS OF THE RHINE,
By Prof. Trousseau and Dr. Lassaigne.
(Continued from page 324.)

Hypochondriasis.—We have here the "bonâ fide" disease, which is to be met with at every spa, as inseparable from the mineral wells, as their advertising pamphlets and Sunday concerts. At Hombourg, and at Nanheim, at Soden, and at Kreutznach does hypochondriasis take up its summer quarters; and wherever it can find a sufficiency of acidulated waters, and of chloride of sodium. The ancient physicians made it a precept to study acute disorders during the progress of great epidemics, the frequency of the cases rendering more obvious their differences and their analogies. The same advantage in the observation of chronic diseases is to be met with at the spas; but it is not sufficient that a common feeling of hope should congregate patients around the wells, curious observers must also resort to the spot, willing to take the trouble, or rejoicing in sufficient leisure, to collect the melancholy treasures of knowledge. The resident physicians have something else to gather besides pathological information; in their eyes the disease is naught, considered independently of its treatment. They know nothing of gout and gravel; they know only of waters curing gravel and gout.

Unsolicited by the same interests, we may profit by the great opportunities afforded us, certain that the subject will amply repay the labour of investigation. However long may be dissertations on chronic maladies, they will almost unavoidably be found too short. Some of their thousand shapes and varieties are inevitably omitted. Nothing is more difficult than a candid and scientific appreciation of mineral waters by a writer who has not visited them; indeed, we may consider the task to be beyond the powers of the most distinguished authors; on the other hand, those from whom we generally derive our knowledge of their virtues have always present to their minds the success of their own particular spa, and the practitioners who prescribe the waters only consider the patients; the spa is always chosen for the disease, never the disease for the spa. Thus, insisting chiefly upon pathological detail—looking upon maladies not in the light of accessories, but as the principal part of our subject—we will follow the same logical order of ideas as the physicians, for whose perusal these pages are chiefly intended. Perhaps we may be in contradiction with many ideas circulated by the physicians of the spas, it is to us of little import; it is not our object to afford any information to the directors of mineral wells.

In Germany every one believes in, nay every one explains, hypochondriasis. In France, the very existence of the disease is doubted by many, and the recitals of hypochondriasis are often taken for the vagaries of disordered imaginations, or for the premonitory signs of some serious organic lesion. Let unbelievers travel as far as Hombourg—let them visit the banks of the Rhine—and they will return with a full conviction of the truth of those opinions they now call in question.

The nature of this singular disease readily accounts for hesitation and doubt. Hypochondriasis is not a malady like pneumonia, but a morbid condition, in which all the viscera take share, and which borrows a different character from each of its influences. Its isolated symptoms are of no value, but, when united, they form an amount of suffering which may, if neglected, end in some incurable lesion. Hypochondriacal symptoms are eminently transitory, and introduce better defined morbid manifestations. In one you will observe incipient asthma; in another, the first indications of chronic dyspepsia; a third is affected with piles; a fourth is troubled with gout or hemicrania; but cast one glance on the "*tout ensemble*" and you cannot fail to discover that these apparently divergent roads start from *one* spot; in medical language, the

disease presents common symptoms in separate forms.

The leading feature of hypochondriasis is its origin from abdominal derangement; another, is its tendency to produce erratic symptoms. The patient complains of dull abdominal pain, of vague sensations of uneasiness towards which he always looks back as the source of all his sufferings. If these manifestations be accompanied with any physical signs, distention of the stomach, flatulency, &c., are observed from the beginning. In a word, and the remark is not a new one, hypochondriasis does not exist, if the disease does not first occupy the hypochondria.

Chronic enteritis, obstinate diarrhœa, rebellious vomiting, must not be confounded with the malady under consideration. Once cured by the benefit of art or of nature, no more notice need be taken of them; to the hypochondriac, on the contrary, no interval of health can give the certainty that the cure will be permanent. Months may elapse in apparent health, when suddenly and without any visible cause, the symptoms return. This is not the result of mental pre-occupation, the patient had forgotten the disease; it is the disease which forces itself upon his memory.

Together with abdominal pain, melancholy pre-occupations return. They are not, as has been asserted, a form of mental aberration. Nosophobic patients, often cured with micæ panis pills, should not in any instance be confounded with hypochondriacs. Hypochondriasis is a special malady, marked by three distinct characters, abdominal derangement, erratic symptoms, and mental perturbation. Have its anatomical lesions ever been detected by the dissector? Germans say yes; most French physicians will answer no. Even for those who do not in these matters adopt the views of our German neighbours, it is necessary to have them present to the mind, in order to make a profitable visit to the spas. Pamphlets are every day circulated for the purpose of informing the world of the numerous advantages of the Hombourg hotels and tables d'hote; it surely is not very injurious once, by accident, to endeavour to spread amongst the medical public the local scientific doctrines.

The Germans have preserved in their integrity the opinions of Stahl and Fr. Hoffman on chronic diseases. These two great masters professed that hypochondriasis arose from a primary derangement of the circulation. They supposed that the blood equally divided between the viscera, was either continuously or at irregular intervals carried in excess towards the abdominal organs; hence the various symptoms of what has been called abdominal plethora. When the local circulation merely undergoes an increase of activity, no chronic inflammation can arise, but this derangement of equilibrium in what Puchelt calls *arterial* subjects (Syst. of Med. Heidelb. 1827), constitutes a predisposition to acute inflammation. Insufficiency of the venous circulation, on the contrary, promotes passive congestions, and that form of disease vaguely denominated obstruction by old writers.

This sluggishness of the abdominal veins is explained and encouraged by the anatomical disposition of the portal system, by the presence of permeable conglobate glands, and the vascular structure of the mesentery. The best demonstration of medical facts may be obtained by a method much in use amongst mathematicians; let us for an instant consider as proved this hypothesis of venous sluggishness, and see if it can account for the symptoms observed.

Venous abdominal congestion may result from one of two causes, a lax habit of the constitution, or any local constriction of the body, by which a portion of the circulating fluid is mechanically poured into those parts best calculated for its reception. Hypochondriasis belongs to the second order of causes, an opinion which seems confirmed by the metastatic changes observed in its symptoms. These are referred by persons accustomed to the study of insanity, to moral pre-occupation; and, by the sectarians of the school of Haller, to disturbed equilibrium of the circulation; two opinions between which we would feel no embarrassment in making a choice. Follow the progress of the symptoms:—the patient at first complains of vague and erratic pains, of a sensation of weight, but of no functional disturbance. Pain is already present, but digestion is regular, and the activity of the system is preserved. Dyspeptic symptoms make their appearance, and a gastric affection might be diagnosed, but that the hypochondria and the lower region of the abdomen are alone the seat of pain; flatulency and costiveness are soon noticed, together with the inseparable companions of the latter, fatigue of the extremities, headache, and mental lassitude. The patient becomes alarmed; he had been hitherto pre-occupied, he now is seriously uneasy. When questioned on his ailments, he loses his habitual taciturnity, and the narratives of all hypochondriacs present a character of sameness which must strike even an inattentive observer. Such is the first stage; it is seldom studied, because the patient has not yet thought it necessary to seek professional assistance, which at this period might be effective. Repeated laxatives are almost constantly successful, and it is in such cases that we have found the waters of the Source Elizabeth, at Hambourg, of the greatest possible benefit.

At a more advanced period, the symptoms still referred to the abdomen have acquired a greater degree of intensity; deep-seated colic, analogous to that which precedes menstruation, throbbing in the side, abdominal distension, occasionally so intense as to occasion dyspnœa, loss of appetite, appear together; the attacks last one or two days, and are followed by comparative healthy; flatulency and costiveness become the leading symptoms, and the excretion of urine is attended with slight pain.

DAN. M'CARTHY, D.M.P.

Germany.

EGYPTIAN OPHTHALMIA OCCURRING IN THE AUSTRIAN GARRISON OF MAYENCE.—Dr. Muller of Mayence has published a paper in the *Zeitschrift fur die Gesammte Medicin* on a form of Egyptian ophthalmia which he has lately observed among the Austrian garrison of Mayence. The disease commenced under the following circumstances. In the autumn of 1845 a camp, in which the troops were changed every eight days, was established about half a league from the town. The exercises, which were carried on during the day, took place on very sandy ground, and the soldiers passed the night in little tents containing about eight men each. They lay on the ground on straw with their cloaks and blankets. The heat, in consequence of crowding, was so great that the men were often obliged to undress themselves. Notwithstanding this, a few cases of rheumatism, and diarrhœa excepted, the general state of the camp, after it had been established some weeks, was very satisfactory. The soldiers' diet was the same as usual, although perhaps they drank more brandy than usual; excesses however when discovered were severely punished.

In 1818 a very severe epidemic of the Egyptian form of ophthalmia appeared in the Prussian garrison of Mayence, and from that period occasional sporadic cases of the disease had been seen, but never among the Austrian soldiers. Attacks of ophthalmia, which were at first supposed to be rheumatic but which were soon found to be slight forms of Egyptian ophthalmia, having then been found to exist in the camp, it was immediately broken up. On the 20th of September 1845, five weeks after the establishment of the camp, symptoms of Egyptian ophthalmia were remarked. The soldiers first attacked had only a slight inflammation of the conjunctiva; but at the external angle of the lower eyelid, just towards its centre, rounded phlyctenæ were observed, like the blisters of typhus; there was neither photophobia true inflammation, fever, nor any other functional disorder: in a few cases only the patients complained of a feeling of irritation and of seeing colours round the flame of a candle. The first day the number of sick amounted to 100, and at the end of the week 1000 men were attacked,—a quarter of the whole Austrian garrison. Recourse was immediately had to cauterisation with nitrate of silver, which had been regarded as a specific by the Prussian garrison in their attacks of the complaint. On the 28th of September, the 8th day of the epidemic, Dr Esihler, the surgeon general, showed the author of the paper a hundred patients, ten of whom had been recently attacked, and the remainder of whom had been cauterised. The following symptoms were observed among the ten recently attacked in whom no treatment had been practised. Look free; the globe of the eye clear and not more moist than natural, the eyelids neither swollen nor red, without lachrymation or increased flow of mucus; on depressing the inferior palpebra several phlyctenæ were seen in the external angle, in the commissure of the ocular and palpebral conjunctivæ; one of these was usually placed higher than the others, isolated, and was generally the first to appear and the most developed; by degrees the vesicles extended towards the middle of the eyelid and covered almost all its internal surface; in other cases the greater part of the surface remained unaffected, and a chain of vesicles only existed on a projecting fold of the conjunctiva. The more recent phlyctenæ were small, diaphanous, hemispherical, of the size of a millet seed or rather less. The conjunctiva was at the commencement of the disease marked by several small vessels; but by the second or third day it became of a brighter colour, sometimes purplish and covered by numerous papulæ. The folds of the lachrymal caruncle and of the conjunctiva always remained in a normal condition, the ocular conjunctiva being always clear; the ends of the vessels, from the palpebral conjunctiva, were sometimes only seen to ramify in it, but they never reached as far as the cornea, which was always clear and transparent. The upper eyelid, the lachrymal gland, the lachrymal canals, and the glands of meibomius were not affected by the disease, except by a slight increase of their secretion, which continued altered in quality.

In the eyes which had been cauterised, the eyelids were more or less swollen, and the conjunctiva covered by white scars, after the detachment of which little pointed papillæ were seen, which covered the whole conjunctival surface of the lid by degrees, and gave it the appearance of velvet, furrowed by more or less voluminous vessels. The ocular conjunctiva and the sclerotica appeared irritated after the cauterisation, which was occasionally repeated in order to repress too high granulations.

The Prussian hospital contained thirty-five soldiers affected by ophthalmia, out of 1360 Prussians composing the camp. This ophthalmia differed considerably from that affecting the Austrians. The lids were swollen, the conjunctivæ of the inferior lid and of the globe of the eye were highly injected, swollen, covered by granulations, folded and moveable. At the external angle of the eye there were found several little sacs; the caruncula lachrymalis and the semilunar fold were red, injected, and swollen; the secretion of the tears was slightly increased, and their discharge easy; and the meibomian glands discharged a good deal of pus. At the commencement of the disease the soldiers experienced a good deal of itching in the eye, dazzling and slight insufferance of light. This was the state on the second day. After a few days the use of fomentations, with a strong solution of nitrate of silver, and friction with mercurial ointment in the supra-orbitar region, there was a considerable diminution in the mucous secretion, in the swelling of the lids, and in the conjunctival granulations. By the fifth or sixth day of treatment the granulations had almost entirely disappeared. Still, however, the conjunctiva preserved a velvety appearance, and a redder purplish tint than natural, which extended to the globe of the eye. The treatment described, continued during ten or twelve days, succeeded perfectly without any derangement in the func-

tions of the eye. In the most serious cases with more prominent granulations, recourse was had with success to the use of the nitrate of silver in substance. Bleeding was never employed in the worst cases. M. Bock, the surgeon of the Prussian garrison, administered tartar emetic in somewhat large doses, and caused a concentrated solution of nitrate of silver to be dropped into the eye every two hours, at the same time carefully removing the little concreted masses of mucus. If considerable chemosis took place, he removed the swollen conjunctiva by means of scissors, and then applied the nitrate of silver in substance.

The causes to which this epidemic was attributable were, the chills taken during the night by sleeping on the ground in confined tents; the effects of the dust and of the very bright sunshine reflected by an immense sandy plain; perhaps also the excessive use of brandy. The phlyctena eruption was the characteristic mark of this epidemic; all the other symptoms, such as inflammation and discharge, being only consecutive. The author of the paper regards the opthalmia, observed in the Austrian garrison, as a more benign form of the same disease which raged among the Prussian soldiers. The disease could be communicated by contact.

RESULTS OF AUSCULTATION AT A TRIPLE BIRTH.—Professor Naegele, jun. has published the following interesting account of a case of triplets in the *Medicinische Annalen*. The woman was a primipara, aged thirty-two. At the moment when her labour commenced, auscultation was used, and the double tick of a fœtal heart, with the simple *bruit de souffle* of a cord was heard in the left hypogastric region. The same phenomena were present in the right hypogastric region together with other double sounds. Two auscultators applied the stethoscope, one on the right, the other on the left side of the woman, they noticed that the fœtal pulsations were more frequent on the right side than on the left, in the proportion of thirty-eight to thirty-six, in the quarter of a minute. Soon after, when the right fœtus moved forty pulsations in the quarter of a minute were counted for its heart, thirty-six for that of the fœtus on the left side, making thus a difference of sixteen pulsations in the minute between the two infants. After the birth of the first child with the aid of the forceps, the mother was examined again with the stethoscope, and the pulsations of two fœtal hearts were still heard distinctly of which one was situated in the left hypochondrium, and the other in the right umbilical region. The head of the second child presented in the second position, and the pulsation heard to the right belonged to this child, which was also delivered by the forceps. After the birth of this child, the pulsation of a third fœtal heart was still heard distinctly, and this child was born by the unaided efforts of nature. The entire duration of the labour was fifty-seven hours. The first diagnosis given was, that there was more than one child in the uterus and was founded on the distinct hearing the pulsation of two fœtal hearts. It was only by auscultating after the birth of the first child, when double pulsation was again heard clearly and distinctly, that it became possible to ascertain the existence of three infants. The pulsation of the third fœtal heart was not heard at the commencement of labour, because the infant was most likely situated behind the others towards the spine of the female. The uterine bruit de souffle was neither louder nor more extensive than usual, and could not cause the presence of the placenta to be suspected.

A CASE OF POISONING BY NITRIC ACID, IN WHICH THE MUCOUS MEMBRANE OF THE STOMACH SLOUGHED AND WAS DISCHARGED BY VOMITING.—Professor Puchelt relates in the same journal the following highly interesting and very uncommon case. Caspar R——, a locksmith, much addicted to drunkenness and living in misery, swallowed on the 19th of May, 1845, about two hours after dinner, at which he had eaten some cheese, two ounces of nitric acid. He was immediately seized by violent pain in the mouth, pharynx, and œsophagus, and vomited frequently so that he threw up the greater part of the acid It was not until the 21st of May, 36 hours after the poisoning, that M. Puchelt saw him at the hospital, up to which period he had only received an oily emulsion. The buccal and pharyngeal mucous membranes were covered by shreds of white membrane already partly detached. The velum pendulum palati and the tonsils were swollen, painful, and injected; around the mouth there existed some yellow spots, caused by the action of the caustic on the epidermis: the patient was only able to swallow liquids, his respiration was difficult, but the epigastrium was not very painful; the muscles of the anterior abdominal wall were so contracted that they approached the vertebral column The pulse was small and tranquil, and the intellectual faculties unaltered the urine and stools were normal, and his general state did not seem very alarming; leeches were applied to the epigastrium, and an oily emulsion administered with sugar and water for drink, and gargles of warm water. The symptoms continued much the same for several days, the epigastric pains becoming worse from time to time. Leeches were applied several times, fomentations of chamomile were employed and demulcents administered. On the eighth day the mouth and throat were so easy, that the patient felt an appetite and even ate some food, still however his strength diminished, his appearance became unfavourable, and on the third of June he vomited several times. On the fourth he passed a little blood with his stools; during the night of the fifth he experienced very severe pain in the epigastrium, with anxiety, fainting fits, nausea, and even violent vomitings containing black, fluid blood, and a membrane a foot in diameter rotten and black, as if burnt in some places, and having several holes in it of greater or less size, giving off a gangrenous odour; this membrane enclosed vessels of considerable size with their ramifications; its structure was fibrous, and it possessed very little epithelium. The patient had after this vomiting a stool containing much black and putrid blood, he became very weak and depressed in spirits, and often spoke of death; his pulse was small and frequent: he had acute pain in the epigastrium, increased by pressure, and complete insomnia. An opiate emulsion was administered with slight relief and broth and milk were ordered On the eighth, in the morning, more vomitings took place, with stools of black and fluid blood; the whole body gave off an insupportable smell, the extremities were cold and the pulse small and very frequent; the eyes glassy; delirium from time to time, and afterwards a recurrence of the vomiting of blood. Death took place on the tenth twenty three days after the acid had been swallowed, and sixty-six hours after the discharge of the membranes of the stomach. At the post-mortem examination, the dura mater and its sinuses, were found natural; the arachnoid whitish, opaque, and containing a little fluid, the brain normal; the ventricles containing a good deal of serum; the lungs emphysematous in several places especially towards the right side, a few tubercles at the upper parts of the lungs; adhesions of the pleura on the left side; heart normal, loaded with fat, and the left ventricle and the aorta containing blood. In the abdomen, the left lobe of the liver advanced so far that it covered the stomach and the transverse arch of the colon, to which it was adherent; no effusion in the peritoneum. After having detached the left lobe of the liver with the colon to which it adhered, a cavity was entered which replaced that of the stomach. This cavity extended from the œsophagus as far as the duodenum, into the openings of each of which the finger could be inserted; the walls of this cavity were formed, in front by the concave surface of the liver and the transverse colon, and below by the remains of the membranes of the stomach; behind by the membranes of the stomach, grangrenous, and in a state of putrefaction; to the left by the spleen and a small remaining portion of the walls of the stomach. There was then absence of the anterior wall of the stomach, of the smaller curvature and of a portion of its superior wall. The matters contained in the stomach, were kept in place by the other organs. The liver and the transverse arch of the colon were attached strongly together as far as the pylorus by exudation of lymph, and thus replaced the anterior wall of the stomach; the surface of the liver was covered by a pultaceous dirty fœtid mass of a blackish green colour; a similar mass was found in the cavity of the stomach; the serous covering of the liver was uninjured, and under it no vestiges of the membranes of the stomach were to be found. For the rest the liver itself was healthy enough, and neither much nor little injected; and the gall bladder normal. In the neighbourhood of the pylorus, the portion of the walls of the stomach which remained, was full of holes through which a sound could be passed as far as the walls of the transverse arch of the colon. What remained of the base of the stomach, was so soft that it tore on the least traction, and was adherent to the spleen and diaphragm. The serous membrane of the spleen was uninjured, but thicker than natural. The duodenum and the other intestines were normal but contained, especially the transverse arch of the colon, a considerable quantity of coagulated blood. The œsophagus was completely stripped of its mucous membrane, and the naked muscular fibre was in some places red, in others, black. Neither contractions nor perforations were discovered in the tube. The papillæ of the tongue, strongly projecting were covered by effusion. The bladder and kidneys were normal, the latter being covered by a good deal of fat. This case is interesting inasmuch as it shows that, as assumed by Majendie, vomiting may take place by the action of the diaphragm and abdominal muscles only. The stomach plainly could have no power to reject its own substance.

STATISTICS OF PNEUMONIA AND PLEURISY. Dr. Hauff of Kercheim, in the *Medicinisches Correspondenzblatt*, gives the following statistics of pleurisy and pneumonia. Out of seven thousand eight hundred patients, M. Hauff has treated five hundred and eighty-five cases of pneumonia and pleurisy; of these two hundred and seventy-four occurred in men, and three hundred and eleven in women; thus according to M. Hauff's observations, and contrary to the generally received opinion, more women than men are affected by those diseases. The inverse proportion however took place during two years, whilst during two other years, the proportion of men attacked, was to the number of women as 1 to 1·15 and even of 1 to 1·85. The mortality following these two diseases appeared to be greater among men than among women. Of the two hundred and seventy-four men attacked, thirty-five died, and of the three hundred and eleven women, thirty-six died. The author thinks the greater rate of mortality among men to be due to their greater neglect in not applying early in the disease, and also that many of them were addicted to drunkenness. The general rate of mortality in pneumonia and pleurisy was 1 in 2[?] attacked.

ORIGINAL LECTURES.

A Course of Lectures on Hernia.

LECTURE 5.

I. PARTICULAR RUPTURES

1.—*Inguinal Ruptures*,

When complete pass through the external abdominal ring, and at their first protrusion through it, having the situation of bubo are sometimes called *Bubonocele*, but when in the male they descend into the scrotum they are named *Scrotal*; and when in the female, into the labium are

known as *Labial Ruptures*. *Inguinal Rupture* are of two sorts, which are named *Oblique* or *External* and *Direct* or *Internal*, according to the course they take in passing from the belly through the external ring, and their situation in regard to the epigastric artery.

a. Oblique or External Inguinal Ruptures.

Oblique Inguinal Rupture follows the course of the spermatic vessels in the male, and of the round ligament of the womb in the female, through the internal abdominal ring into the inguinal canal, where it may remain without passing further. It is then called an *Incomplete Inguinal Rupture* or *Rupture into the Inguinal canal.*

But most commonly it passes lower, through the external ring, and is then said to be a *complete Inguinal Rupture* whether it remains a little prominent, as a *Bubonocele*, or descends further into the scrotum or labium and becomes a *Scrotal or Labial Rupture.*

Whilst the Rupture remains in the inguinal canal and is an incomplete, or, as the French call it, an Interstitial rupture, as in the Prep. No. 1316. of the College Collection, in the male, and in Prep. No. 1317, in the female; it is covered by the skin, the cellular tissue, which throughout the body connects the skin with the parts beneath, but is here specially designated, superficial fascia, though in reality no tendinous expansion, by the tendon of the external oblique abdominal muscle, by the cremaster muscle, and the cellular tissue given off from the internal ring to the cord, to form its so called proper fascia. The lower edge of the internal oblique and transverse muscles does not cover it as by some stated, for almost immediately after the rupture bursts through the ring, the edges of these muscles slip up and remain above its neck. When the rupture continuing to descend has passed through the external ring, as in Prep. No. 1319. of the Coll. Mus. it is no longer covered by the tendon of the oblique muscle, but receives in its stead the cellular tissue given from the edge of that ring to the spermatic cord to complete the so called proper fascia of the cord, spreading on the cremaster and blending behind with that other portion which had been given from the internal ring to the spermatic vessels in their passage through it to the inguinal ring. These coverings are well seen in Prep. No. 1320 of the College Collection. Such are the coverings of the rupture sac in the male, but in the female as there is not any muscular expansion on the round ligament, corresponding to the cremaster, that covering is deficient in her, and hence, in woman, an incomplete rupture, as in Prep. No. 1317, is covered only by superficial fascia, by the tendon of the external oblique muscle, and by the cellular tissue, or so called fascia of the round ligament, and when it has passed through the external ring, by the superficial fascia and by the fascia of the cord which are blended together.

The peritoneum in this form of inguinal rupture, first pushes through the internal ring of the transversalis fascia, or cellular tissue connecting the abdominal muscles with the peritoneum, which is situated midway between the upper front iliac spine and the pubic symphisis, and about an inch and a half above the middle of Poupart's ligament, and this spot rather invites to protrusion, as there the process of peritoneum which has already taken the course which an oblique rupture follows, has closed up, leaving generally only a slight hollow, which may be seen by examining the inside of the peritoneum, but sometimes also a little distinct cavity in consequence of the peritoneal covering of the cord not having closed up completely to the inner ring. In some instances indeed the process of peritoneum which the testicle carries with it in its descent into the scrotum, and forming its vaginal tunic, never closes, but remains an open canal along the spermatic vessels to the testicle, so that the general cavity of the peritoneum, and the cavity of its process, the vaginal tunic, freely communicate, and thus a natural bag is formed into which the bowels can at once protrude without disturbing the peritoneum in the least, thus forming a *Congenital Inguinal Rupture* of which Preps. No. 1342—1343 of the College Collection are examples in different stages and the former is remarkable for the testicle being situated at the external ring. This differs from the common or acquired rupture at this part by descending into the open vaginal tunic, which becomes its peritoneal sac, and consequently the bowel under these circumstance is in distinct contact with the testicle and separated from it only by the close investing layer of the vaginal tunic the reflected portion of which forms the rupture ---.

When however, as in the ordinary condition of the parts, the cavity of the peritoneum is completely shut off from that of the vaginal tunic, by the perfect union of the peritoneum which has descended with the testicle, immediately above that gland so as to form its vaginal tunic below and at the internal abdominal ring above, still the intervening peritoneum which covers the spermatic vessels between the testicle and internal ring may be perceived, even in old persons, as a cellular thread, of which Cloquet has given a very good description. He also mentions several varieties which it presents either as a whitish filament which gradually thins and is soon lost in the cellular tissue of the spermatic vessels "on the front of which it always rests, or as a long, whitish, fibro cellular cord which may be followed down to the vaginal tunic, or instead of being full throughout its whole length it encloses here and there little oblong or spindle shaped cavities two or three in number, separated from each other by constrictions, but most commonly communicating with each other by very narrow passages, so that if one be inflated, the others distend like a row of beads." Oftentimes merely a simple cavity is found, an inch or an inch and a half long. The walls of such cavities are more or less delicate and transparent and somewhat elastic, or white, opaque, and easily torn; and their interior is bathed with a reddish serum which may increase in quantity and produce encysted hydrocele of the spermatic cord, "and even in regard to the cavity of the vaginal tunic which generally extends a little above the testicle he observes, I have very frequently noticed the vaginal tunic very much lengthened, ascend in front of the cord even within the vaginal canal, and connected with the depression in the peritoneum by a little band full of cellular tissue."

The rupture sac in oblique inguinal rupture following the course of the spermatic cord downwards, and inwards to the scrotum, and usually in front of the spermatic vessels, which are generally in this close neighbourhood to each other, but not always, as sometimes, though still behind the sac, the artery and vein are widely apart from each other, as in prep. No, 1325, of the college collection, or they may be completely split so that the artery and vein may be on the outer, and the vas deferens on the inner side of the sac, as in prep. No. 1288, of the St. Thomas's collection, or the vas deferens may still remain in its natural place behind, whilst the blood vessels are in front, as in prep. No. 1287, of St Thomas's Mus. These variations from the ordinary disposition of the spermatic vessels require attention, as if overlooked, they will be divided in opening the sac, when placed in front of it, which might be prevented merely by slipping them aside when brought into view.

As the rupture sac leaves the belly in oblique inguinal rupture by the internal abdominal ring it passes over, before and on the outer side of the epigastric artery, which in its passage from the external iliac artery inwards and upwards to the navel, crosses behind the neck of the sac, at right angles with it, and immediately on the inner edge of the internal ring. This is a most important circumstance in connexion with the division of the stricture in oblique inguinal rupture and necessarily forbids the cut for that purpose being made inwards.

b.—Direct or Internal Inguinal Rupture.

Direct inguinal rupture differs from oblique in not passing the inner ring, and along the inguinal canal, but at once though the external ring. The peritoneum as it lines the front and lower part of the muscular walls of the belly, presents a triangular fold, in which the umbilical ligament or remnant of the umbilical artery of the fœtus is enclosed, as it passes from the internal iliac artery up to the navel, and thus forms upon the front of the brim of the pelvis, and outwards to the upper front spine of the hipbone, two cavities, the outer one the larger, in which the internal ring, or rather the part opposite to that ring exists, and the inner smaller one behind the external ring and the part by which it is shut up; this smaller cavity or hollow, is separated from its fellow of the other side, by another fold of peritoneum in which is enclosed the ligament of the bladder, or so called urachus, as it passes from the bladder up to the navel. Thus as in oblique rupture, the little hollow where the peritoneum had passed with the testicle seemed to invite a protrusion of the bowels, so here another little hollow exists, which seems to favour the projection of a direct rupture, but as the external ring is more immediately and closely shut up than the internal, a rupture here is less frequent than through the internal ring. The shutting up of the external ring is effected by insertions of the conjoined tendons of the internal oblique and transversalis, which instead of being continued inwards towards the linea alba, on the same level as that part of their muscular edge, which does not descend on the spermatic cord to form the cremaster, dip down behind the external ring, and are attached to the pubic bone from its spine inwards, to its symphisis, so that when the cord enters the external ring, and is passing through, it has behind it these conjoined tendons, which are further strengthened by the inner attachment of the pubic portion of the transversalis fascia interposed between them and the peritoneum. Sometimes, as mentioned both by Sir Astley Cooper and Cloquet, the tendon of the transversalis muscle has not any attachment to the pubic bone, and under these circumstances the closure of the external ring is effected only by the transversalis fascia.

When a direct inguinal rupture is formed, the peritoneum is pushed out usually between the umbilical ligament, and the ligament of the bladder, and either thrusts before it the transversalis fascia and the conjoined tendons, or bursts through the latter, or if they have not any pubic attachment, pushes out the transversalis fascia alone directly through the external abdominal ring. As the rupture sac with these coverings passes further through the ring, it gets an additional covering, from that part of the fascia of the cord, originating from the margin of the ring, and blended with the superficial fascia, as it descends into the scrotum. Sir Astley Cooper says that the cremaster muscle does not afford it any covering, as in its continuing course it descends on the inside of the spermatic cord into the scrotum. But if my memory be correct, I think I recollect him to have mentioned in one of the last lectures I heard him deliver on this subject, that the rupture sac, bursting through the conjoined tendons, was covered on the inner side by the transversalis fascia, and on the outer by the cremaster muscle. And Mr. Lawrence states, that he has seen the cremaster muscle expanded over the swelling.

As this rupture does not pass through the inguinal canal, but directly through the external abdominal ring, it necessarily happens, that the epigastric artery is on the outer side of the mouth of the sac,—as exhibited in prep. No 1324 of the college collection, and No. 1209 of St. Thomas's museum—a circumstance of equal importance in reference to the division of the stricture, as its situation on the inner side of the sac's mouth in oblique rupture.

As to the possibility of distinguishing direct from oblique inguinal rupture when of long duration, I have great doubt, for where an oblique rupture has long existed, and is of any great size, the internal ring is more or less completely dragged down to the external, and the inguinal canal so entirely destroyed, that the finger is readily passes the external ring into the belly, as it does in a direct rupture. But in the early part of their existence, they may be distinguished

In the early period of oblique inguinal rupture the oblique course from above inwards and downwards, and the filled inguinal canal may be distinctly perceived, and the swelling is greater below in the scrotum, than it is at the external ring. On the contrary, in direct rupture, there is not any swelling in the direction of the inguinal canal, but the tumor proceeds straight through the external ring and passes into the scrotum. In one case which I saw six or eight hours after its occurrence, in a slight young man, produced by the slight exertion of sweeping a lawn, and which seemed to me a case of direct rupture, the swelling which had descended about three fingers breadth, directly from the ring, without any fulness of the inguinal canal, was really of the same thickness throughout, its diameter being about that of a couple of fingers. Whether such be the case always, at the first appearance of direct rupture, I do not know, as I have not seen another at so recent a period; but it was very remarkable in this instance, and if constant, would form another distinctive character of this form of oblique inguinal rupture.

C. OF ENCYSTED INGUINAL RUPTURE.

Sir Astley Cooper has described a form of congenital oblique inguinal rupture, which he called the encysted hernia of the tunica vaginalis, in which, on opening the tunica vaginalis, instead of the intestine being found lying in contact with the testicle, a second bag or sac is seen enclosed in the tunica vaginalis, and enveloping the intestine. This bag is attached to the orifice of the tunica vaginalis, and descends thence into its cavity; it generally contracts a few adhesions to the tunica vaginalis, which, in its interior bears the character of a common hernial sac. He considers in this case, that "the tunica vaginalis, after the descent of the testicle, becomes closed opposite the abdominal ring, but remains open above and below it. The intestine descends into the upper part, and elongates both the adhesion and tunica vaginalis, so as to form it into a bag, which descending into the tunica vaginalis below the adhesion and becoming narrow at its neck, though wide at its fundus, receives a portion of intestine." This is a form of rupture of very rare occurrence, and its formation may be either as Sir Astley Cooper states, or it may result after the obliteration of the neck of the sac, by wearing a truss in either kind of the inguinal rupture, provided the sac be not completely closed up to its mouth. In either case the bowel driving into the hollow, however small, above the adherent part, would thrust it down, bringing with it more peritoneum from the cavity of the belly, and thus a new and second rupture sac would be formed; which, as it descended, would pass lower and lower into the inguinal sac, and thus a double sac would be formed.

Precisely the same process takes place when a rupture and hydrocele exist together, whether a hydrocele first existing, a rupture forms afterwards, and descends as low as the distended vaginal tunic, as in prep. No. 1337, of the coll. mus.; or it may even drive down into it, so that the rupture sac is nearly surrounded by the vaginal tunic, as in prep. No. 1339; or whether the rupture be first formed, and the hydrocele occurring afterwards, as it increases, rises upwards with the bottom of the sac. In either case the remnant of the peritoneal covering of the spermatic vessels between the rupture sac, and the hydrocele is either absorbed or compressed into a smaller space proportioned to the distance between the hydrocele and the rupture sac.

The cases in which the rupture sac has been found behind a hydrocele, first noticed by Mr. Thomas Blizard, and subsequently by Sir Astley Cooper and Mr. Henry Cline, and which have since been found to be more frequent than supposed twenty-five years since, appear to me readily explicable in the same way. A hydrocele exists —a rupture descends till it reaches its upper part, and the disposition to protrusion still continuing, the sac begins to drive down behind the hydrocele, and probably as it lengthens, rolls down with it the back of the distended vaginal tunic, which thus [illegible] a second peritoneal covering in front of the rupture. Or a rupture may first exist, and a hydrocele subsequently forming, may, as it grows, ascend in front of the rupture sac, and thus the same condition of parts be produced, with the mere difference that the hydrocele ascends before the rupture, instead of the rupture descending behind the hydrocele. The fluid of the hydrocele does not necessarily remain; in Mr. Thomas Blizard's case it was absorbed, but in Mr. Henry Cline's, which I saw operated on, it poured forth when the vaginal tunic was opened.

These are the only kinds of rupture in which a double peritoneal sac can exist. When the adherent neck, in a congenital rupture descends vertically into the vaginal tunic, then the double peritoneal sac is complete all round; but when the rupture descends behind a hydrocele, then the peritoneal covering is double in front only, and not behind. In both cases, however, the testicle will be exposed in the course of the operation.

Many swellings of the scrotum, or rather of the parts which it contains, are liable to be confounded with ruptures, either just after their protrusion from the external ring, or when they have descended into the scrotum. The distinction, however, is generally not difficult; often, even with a slight examination, and when taken in connexion with the previous history of the case, and the constitutional symptoms. Hydrocele of the vaginal tunic of the testicle, although somewhat of the same form, especially if of large size, and as occasionally extending up the spermatic cord to the ring, and even into it, is distinguished by its transparency, by its first appearing at the bottom of the scrotum, and gradually ascending in proportion to its bulk; but I have never seen a single instance, however high a hydrocele might ascend, in which it was not possible to nip the cord between the top of the distended vaginal tunic and the external ring, and so ascertain that it has not any communication with the belly. Of course it undergoes no alteration in size, whether the patient be standing or lying down, neither does it dilate or increase on coughing, or any other effort by which the bowels are acted on by the abdominal muscles. One kind of hydrocele, which is, however, far from frequent, is liable to mistake; it is the congenital hydrocele, in which the vaginal tunic, not being closed at the internal ring, the fluid contained in it will swell out the hydrocele sac in the erect posture; but flowing back into the belly when the person lies down, the swelling disappears. But this may be, without difficulty, distinguished; because if it were a reducible rupture, which returned into the belly on lying down, the fingers placed against the ring would, in most cases, prevent the protrusion of the bowel, when the patient stands erect, and consequently, there would not be any enlargement of the scrotum. But in congenital hydrocele, though pressure be made on the ring, the fluid will ooze through the mouth of the sac into the hydrocele sac; and though not so quickly, yet as certainly at last distend it to its former size.

The more rare form of hydrocele, that of the spermatic cord, is more liable to be mistaken for a bubonocele, or inguinal rupture, which has just passed through the external ring. I have seen two or three instances in which this mistake has been made, and an operation thought requisite. A curious circumstance with respect to the hydrocele of the cord is, that the person sometimes says, it has appeared suddenly, and after additional exertion. Such was the statement in reference to the last two cases I saw—one of which was under my own care very recently. It would hardly seem possible that it should have been produced at once, or even in the course of a few hours; but the patients were positive about it. The appearance of such cases very closely resembles a bubonocele; but as in common hydrocele, the spermatic cord may always, with a little management, be grasped above it, and its complete independence of the cavity of the belly ascertained.

Varicocele may be mistaken for rupture, especially if the veins be very much enlarged. Like rupture, it increases in the upright posture, and mostly disappears in lying down. But if the fingers be placed on the ring, and the patient directed to stand up, the swelling not only re-appears, but is of larger size than before, because the pressure, though insufficient to prevent the blood passing through the spermatic artery, is sufficient to prevent its return by the veins, which consequently, become largely distended. This quick and increased bulk readily distinguishes varicocele from hydrocele, from which it is still further discerned by the knotty, rope-like, and general thickness of the whole cord, from the testicle upwards, and by its want of transparency.

Thickening of the cord from chronic inflammation and suppuration in the cord, which last is extremely rare, are said to be capable of mistake for inguinal rupture; and enlargements of the testicle of any kind are said to be so too; but mistake of either of these conditions can only arise out of great carelessness.

An arrest of the descent of the testicle at the abdominal ring, may be mistaken for rupture, but may be distinguished with a little management and tenderness, by keeping the finger and thumb on the cord between the testicle and the ring.

Rupture may be complicated with hydrocele, as I have already mentioned; and the rupture sac may either descend only to the top of the hydrocele, as in prep. 1338, of the college collection, or even not so low, or it may pass down behind it, as I have shewn. I may, however, observe that in a person of lax habits, a heavy hydrocele constantly dragging by its weight upon the cord, would certainly predispose to an oblique rupture, as it would be constantly pulling that part of the cord fascia arising from the inner ring, and thus produce a little hollow, into which, by the ordinary pressure of the abdominal muscles upon the bowels, the peritoneum would be forced, and thus the beginning of a rupture sac be formed.

The absence of all symptoms of strangulation, or those accompanying peritonitis would prevent in the first instance, any mistake as to the swellings of the scrotum from ruptures or other causes. But when such symptoms occur, and such swelling of the scrotum also exists, then the attention must be directed to ascertain the true character of the tumor.

A Course of Lectures on Diseases of the Skin.

By JAMES STARTIN, Esq., Surgeon to the London Cutaneous Institution.

LECTURE XIX.

RUPIA AND ECTHYMA.

According to Willan and others.

GENERA	SPECIES.
Rupia	R. Simplex R. Prominens R. Escharotica
Ecthyma	E. Vulgare E. Infantile E. Luridum E. Cachecticum

As proposed by Startin.

GENUS.	DIVISIONS.	FORMS.
RUPIA R. Simplex vel Sero-sanguinosa R. Ecthymata vel Pustulo-sanguinosa Escharotica vel Gangrenosa	Localis Generalis	Acuta Chronica Insulata Sparsa Conferta

GENTLEMEN,—The cutaneous diseases on our chart which present themselves next in succession to sycosis, and somewhat resemble this malady when in an insulated form (both as regards the place they occupy when situated on the face, and also in their external manifestations after their earliest stages have passed), are those designated rupia and ecthyma. I purpose considering these as one disease, having a sero-sanguineous and a pustulo-sanguineous variety. Most authors on skin complaints, since the time of Bateman, have allowed that, as regards all practical purposes,

this arrangement would have been sufficient, as both maladies occur under precisely the same states or conditions of the constitution. But the orders into which cutaneous diseases have been arbitrarily and somewhat incongruously divided by authors, would then be inapplicable to the two affections, as pustules and vesicles must have been united, instead of constituting a distinct class of complaints, as they are now made to do. This is done at the expense of simplicity and natural arrangement; both appearances being constantly found co-existing in the same patient—a remark I have before had occasion to make when speaking of another pustular and vesicular disease—impetigo and eczema. The reductio ad absurdum of such a system is, however, in my opinion, accomplished by its originator and advocates placing the small-pox, and common itch, under the same order; because pustules may, at some precise moment of the existence of these diseases, be their common characteristics.

The term rupia, which has hitherto been applied to a vesicular disease, only occurring in a vitiated state of the general health, is derived from a Greek word signifying sordes, as indicative of the diseased and sordid condition of the parts affected; it is, therefore, equally applicable to the complaint known as ecthyma, when this state of the body obtains, only that pus may be more commonly formed in its earlier manifestations, often intermixed, however, with vesicles. The definition I would, therefore, propose for rupia is, that it consists of a non-contagious eruption on the skin of flattened vesicles or pustules resting on a more or less inflamed base, their size varying from that of a small-sized button to that of a halfpenny. The fluid contained in these eruptions may be of a sanious or puriform nature, but they speedily break in their centres, and concrete into an adherent, hard laminated scab of a dark reddish brown colour and considerable thickness or prominence, which covers ulcerations of greater or less depth and extent.

When a sanious fluid is secreted in the diseased parts, these encrustations are commonly superficial, on the other hand, when their contents are purulent or sero-purulent, the crusts are seldom so prominent, and they are found embedded in the inflamed portions of the skin on which they are situated—a fact rendered evident by an inspection of the models of this curious disease which are arranged for your observation; but also conspicuously seen in the individual attending, whose case I shall presently allude to.

Rupia is so rarely witnessed, unless as a symptom of some constitutional disorder, or cachexy of the system, that its appearance may constantly be regarded as a pathognomonic sign of the existence of one or the other state in the individual attacked with the complaint. Thus it is most frequently seen amongst the poor and squalid, residing in ill-ventilated, unhealthy localities, or those persons who have suffered from lingering illnesses or undergone long courses of medicine, particularly in cases were iodine has been taken. This was the case in the patient I have had the pleasure of showing you, as this poor man had been afflicted with inveterate lepra vulgaris *for fifty years*, for which he had been under treatment here for a month or two, and had been subjected to the influence of iodine in combination with other remedies, principally chalybeates. He had not taken arsenical, or mercurial medicines whilst under my care, but had used the iodide of sulphur as an ointment, and bathed twice or thrice a-week in an alkaline bath, which occasionally was suspended for the vapour bath. By these means his skin had become quite clear, and the leprosy, in most situations, had disappeared, indeed, as the patient told you, "he had not been so well for fifty years;" nor is his general health disturbed. Within the last week or ten days, I perceived an eruption on the legs of this patient, which answers to the malady Willan has called ecthyma cachecticum, and which I attribute to the effects of the iodine, as I have many times witnessed a similar occurrence; perhaps, also, the bathing has had a share in its production, for what the hydropathists call *their crisis* is no more nor less than a similar eruption to that you have witnessed.

No part of the body is exempt from rupia, and every age and sex is subject to its attacks; yet it seldom, if ever, appears in the healthy and well fed, unless as the sequel of some debilitating bodily or mental cause.

I feel inclined to agree with the view taken by Plumbe of this disease, "that it is clearly dependent on a similar state of the vessels of the skin to that giving rise to the formation of petechiæ;" and that lesion of some capillary vessel takes place in every spot on which a vesicle or pustule of rupia is discovered. Thus the inflammatory action accompanying the disease, the ulceration and encrustation, are the there natural processes first to remove, and afterwards to repair the mischief; the precise manifestations of the eruption being always regulated by the constitution of the patient, and other circumstances as readily appreciated.

Willan divided ecthyma into four varieties, resting entirely upon these modifications, which he called E. vulgare, E. infantile, E. lividum, and E. Cachecticum, a very needless complication, and one leading to no practical result. Rupia he also considered under three species, R. simplex, R. prominens, R. escharotica. With your permission I propose to simplify this subject by comprehending both diseases under the term rupia, which, as I have written on the chart, I shall divide into three species, designated from their most prominent marks, rupia simplex, vel sero-sanguinosa, R. ecthymata, vel pustulo-sanguinosa, and R. escharotica, vel gangrenosa. These three species may be local or general, and they may appear in a chronic or acute form, and insulated scattered, or grouped together on the part of the body they infest; it is not uncommon, in severe cases, to witness two or more of the species existing on the same patient. In addition to the constitutional causes of rupia, as above divided, it may be produced by any long-continued inveterate irritation of the skin; for instance, it is a very usual sequel of scabies amongst the poor and destitute. I have also occasionally witnessed its production from the irritation of various mineral substances amongst colour-makers, drug grinders &c.

Tartar emetic, as is well known, occasions an eruption of rupia ecthymata, and arsenic and other caustic irritants have the same effect in those subjects who may be said to have a predisposing idiosyncracy.

Rupia simplex is a form of the disorder which consists mostly of a scattered, successive eruption occurring on the extremities, the buttocks, shoulders, and other parts of the body), of red, flattened tubercles, which, in a day or two, produce a vesicle, filled with a sanious lymphatic fluid, that rapidly enlarges whilst the base becomes inflamed and more or less indurated, each eruption pursuing a course somewhat independent of those around it. In four or five days, or a less period, from the commencement of this disease, the vesicles break, and discharge their contents, which shortly concrete into brownish-red scabs, whilst the surface below them consists of a smooth polished ulcer, that has little tendency to heal, but keeps enlarging by the circumference, and pouring forth its secretion, which concretes layer after layer until a thick, laminated, and sometimes conical scab, is produced (the rupia prominens of Willan). This eruption is attended with stinging and smarting pains rather than itching, which are augmented by handling the part, and the constitution is often so affected by them as to manifest more or less feverishness and irritation. When the healing process has been accomplished, either by nature or art, a cicatrix is rarely observable, but the part shows for a long time a dark red spot.

Rupia ecthymata occurs under precisely the same circumstances as those I have detailed as attendant on the preceding species, but pustules are formed instead of vesicles, or the tubercular eruptions which usher in the disease; the inflammation also is commonly more violent in these cases, and consequently there is greater pain and induration, whilst the ulceration beneath the crust is more profound. The circle of redness surrounding this disease in the worst cases is such as to have occasioned Willan to adopt the term ecthyma luridum. There is perhaps a greater degree of pain in R. ecthymata than in the first described species, and the scabs are neither so hard or so prominent as in that affection—the pain, indeed more resembling that which accompanies a boil; but there is no core, or slough in the disease I am describing, which at once distinguishes it from the painful affection alluded to.

I may refer you to several models on the table, which, better than language, will illustrate what I have advanced on this subject; and you will observe on how very slight a difference Willan founded a distinction between two diseases having very constantly a common origin, and requiring a similar treatment. As might be expected in protracted cases, when the ulceration has been deep, both these varieties of rupia occasionally leave small scars on the sites they have occupied, but in the next species this is most remarkable, from causes which will be obvious from the mere repetition of its name, *R. Escharotica vel Gangrenosa*—happily a very rare affection, and occurring only amongst the poorest and most diseased or asthenic subjects—at least, I have never seen it under other circumstances. It commences in a manner precisely similar to rupia simplex, on the thighs, buttocks, genitals, extremities, loins, and cheeks of its victims, which are mostly the young, particularly children, though I have occasionally seen it in adults; at this moment I have a private patient under my care, with a ruined constitution and asthenic, in whom it exists on both legs. It runs, for a variable period, the course of the other species of rupia, manifesting not unfrequently the ecthymatous form, when a black point commences generally on the edge of one or more of the ulcerations, and thence rapidly extends to the sound parts, producing a phagedenic or gangrenous eschar, that assumes a black colour, and when it slowly separates from the living parts, leaves a deep pit and indelible scar—in fact it is phagedenic mortification superadded to rupia, and is very constantly a fatal disease.

With regard to the treatment of rupia, and of the three species I have now described, I think it can scarcely be necessary to say much, as it is strictly constitutional, and therefore must be regarded entirely on the general principles which guide the practice of our profession; no two cases, unless arising from precisely the same cause, requiring similar remedies. I have found the black or yellow wash a better stimulating application to the eruption, in all its stages, than ointment of any kind, and the stronghold, as regards internal remedies, is to be found in the mineral acids, in preparations of Peruvian bark, in large doses of opium, and in diffusible stimuli, particularly ammonia, in full doses. Where a syphilitic taint, or scrophulous complication, may be distinguished, this treatment will of course require modification; and in the rare and dreadful disease called rupia escharotica, the free use of nitric acid or of a solution of mercury in nitric acid (the nitrate acide de mercure, of the French surgeons), is indispensable, and must be applied with no sparing hand.

With regard to the two former varieties of rupia, the practice of this institution furnishes numerous examples of this constitutional scab, and scarcely a day passes that opportunities for observing it do not present themselves, either on the persons of those unfortunate poor people who live in squalor and poverty, in the crowded courts which surround this locality, or in those who have suffered from the pain, torment, and irritation of the skin arising from other cutaneous diseases of protracted continuance. I shall, however, not detain you long in the recital of these cases, merely selecting one or two of the models, by way of example. The instance to which I now point is that of Amelia Shaw, aged 28, No. 5399 in the register, residing in Green-street, Stepney. This chlorotic young woman had suffered four years from her disease, which was a case of rupia ecthymata chronica, confined to one leg. Most of

M.

this time she had been under public medical treatment." The model was taken two months after her admission as a patient; consequently, much of the appearance of the disease first presented had vanished; yet sufficient remains to point it out as a case of what I have called Rupia Ecthymata. You will perceive few crusts remaining; but the pustules and ulcerations are evident enough. Unfortunately, the model cannot show the constitutional symptoms of this case, which were dependent on a scrophulous diathesis and uterine derangement, and probably organic disease — as leucorrhœa, containing shreds of adventitious membrane and curdy matter, in addition to most irregular menstruation, would seem to show more than the existence of mere functional disorder of the part. The treatment adopted has been very various, and it is only within the past month that the last sore has healed; she has thus been a patient of the Institution for six months. Chalybeates, the mineral acids, opium, the biniodide of mercury, in alterative doses, liquor potassæ, bark, and various forms of iodine, have been tried in succession; whilst aluminous and other astringent injections have been directed to moderate the leucorrhœa. Meanwhile the local disease on the cast has been treated with various stimulating applications in ointment and lotion. A wash, composed of calomel and bichloride of mercury, in lime-water, applied by means of a compress and bandage, has proved the most useful application to the ecthymatous ulcerations, and a decoction of bark, with liquor potassæ and laudanum, and biniodide of mercury, at bedtime, in grain doses combined with opium, have proved the most beneficial internal remedies. These united measures have succeeded in ridding this poor girl from the ulcerations which had so long tormented her; yet her constitution is far from re-established, for the leucorrhœa remains, though in a moderate degree, and the cause of the rupia can therefore be scarcely considered to be removed. A strict examination into the uterine disease is what is required, and must be instituted before we can proceed in the treatment of this case.

I have been much interested in this young woman's sufferings, from the fact of having attended a precisely similar case some years ago, which ended fatally; and I here show you the condition of the uterus and its appendages, not so much on their own account (though they afford a rare and beautiful example of tubercular deposition and disease in this part of the body), as to impress your memory with the fact that rupia, as I have endeavoured to describe it, is for the most part a symptomatic disease.

The next case meriting your notice is that of rupia simplex ulcerata, represented by the model marked 5431, appertaining to Thomas Spray, aged 20, a poor, deformed, asthenic individual, who came here on crutches, and in a wretched state of marasmus, from want and poverty. Both legs were affected in this case, though one only was taken by the modellers; and a very painful business it must have been, owing to the ulcerations present with the vesicular disease; yet I can assure you the poor fellow would gladly have had the operation repeated for the small sum I gave him to purchase a little nourishing food, which, more than medicine seemed to be required. On this model you will notice a verification of the remark I have already made, that both the forms—I might almost say the three forms of rupia are sometimes manifested in the same case. The vesicle filled with a sero-sanguineous fluid, in juxta-position with one containing purulent secretion, and ulcerations which have here and there a phagedenic aspect, as though gangrene was about to set in. What could I do with this unfortunate patient, in the way of treatment? I really felt at a loss, and regretted my poverty and that of the Institution which cannot afford a bed for such cases. I sent him, however, to King's College Hospital, with a supply of ammonia and laudanum, in the form of a mixture, that might revive and soothe his immediate symptoms. As I have not since heard of him, I should hope he has been received into that excellent charity, and that his very pressing wants are attended to.

I will relate one case more only of the variety of rupia termed escharotica. I have no model of this disease, but show you a very excellent plate of it in Dr. Willis's Atlas. The instance I am about to refer to is that of the little girl, Mary Simons, aged three, residing in Winchester-street. She was brought to the Institution about two months ago, by her mother, with excoriations in both groins, whilst on the left labium pudendi, a black-looking blister, somewhat resembling that which arises after a violent pinch, was observable. The child was languid, and had no appetite; yet there was no want of flesh; the aspect was pallid and cadaverous. I removed the blister with the scissors, and applied to the dark eschar beneath a little nitric acid, of the P. L. strength, by means of a piece of linen wound round a glass rod. The child did not suffer so much pain as might have been expected, and I directed the mother to take her home, and apply a large fermenting poultice. I also administered, every three hours, a mixture containing one grain of sesquicarbonate of ammonia and one drop of laudanum, and I promised to call the next morning. On my visit, I found the child looking better; it had slept soundly, and taken nourishing food and a little wine; yet two other patches of gangrene had appeared in the centre of the excoriations I have mentioned as existing in each groin. They were small and irregularly oval in shape, and not quite the size of the little finger nail: much dark, mahogany-coloured inflammation existed in both inguinal regions; the cauterised spot of yesterday seemed not to have extended. I applied the nitric acid rather more freely, and to all the gangrenous spots. Intense pain followed the application, but subsided in a few minutes. The medicines were directed to be continued in slightly augmented doses. On my visit next day, I found the little patient better in every respect. All the measures were continued, save that the acid was not re-applied. On the following day, no change in the treatment was advised; the bowels were regulated with castor oil, and in about ten days the sloughs separated, so that in a month the wounds were healed. Scarcely, however, was this accomplished, than the child became infected with measles, attended with so much bronchial inflammation and constitutional disturbance, that it died on the sixth day.

I had intended to have related one or two other cases of this fortunately rare disease (rupia gangrenosa), to show its dreadful nature and fatal tendency, but I think it will be needless. When the face is affected, a cure can only be accomplished with frightful disfigurement, than which death is almost to be preferred. With regard to the other models of R. Simplex and R. Ecthymata, it will suffice to say, that the recital of nearly every example would be but an account of some particular organic malady or constitutional derangement, I shall, therefore not enter upon them. Neither shall I more than make mention of the complications of rupia with syphilis and scrophula, which, as may be surmised, are of frequent and ordinary occurrence, as these diseases, it is well known, produce a cachexy in the habit exceedingly favourable to the production of rupia in all its forms, which I shall have occasion to demonstrate hereafter. I may mention, however, that I will gladly refer to any case connected with the models, on which any gentleman present may express curiosity.

The subject for our next lecture will be the comparatively rare disease known as pompholyx, or pemphigus.

ORIGINAL CONTRIBUTIONS.

NERVES OF THE UTERUS.—CONTROVERSY BETWEEN DR. LEE AND THE COUNCIL OF THE ROYAL SOCIETY.

[To the Editor of the Medical Times.]

SIR,—Though aware of your having positively declined taking any part in the controversy between Dr. R. Lee and the Physiological Committee of the Royal Society, as being a matter of no general interest, but simply a struggle between two cliques, equally base in their views—equally despicable in character—in which view I partly agree—you will, notwithstanding, excuse my requesting your insertion of the enclosed letter, addressed to a gentleman I greatly esteem, and who, though his name be involved in the "meshes of cliquerie," does yet abhor it as strongly as you or any other right-minded person. By doing so you thus enable me to fulfil my promise to Dr. Lee, and, as I trust, to satisfy Mr. Beck (another of the disputants), that I, in no shape, undervalue his labours, but, on the contrary, think very highly of them.

I have the honour to be,
Mr Editor,
Your much obliged and obedient servant,
R. KNOX.

MY DEAR MR. BOWMAN,

After my return to London my attention was first directed by yourself to a communication in the *Literary Gazette* bearing my signature; I applied at the office of the *Gazette* for a copy of the number containing the communication, and the *Gazette* for May 16 was put into my hands. On perusing what is there published with my signature, as reported by Dr. Lee, I cannot find any inaccuracy I should wish to amend; the report is no doubt imperfect, but quite correct so far as it goes. The reason for its publication, however, I did not rightly comprehend until some days afterwards, on meeting with Dr. Lee, who informed me that its hasty publication *had been caused* by a letter of Mr. Beck's, which I would find in a preceding number of the *Gazette*, namely, that for May the 9th. Mr. Beck's letter, it seems, called forth his reply, including my remarks on Mr. Beck's dissections of the nerves of the gravid uterus, made by me to Dr. Lee, on the morning following my examination of Mr. Beck's very valuable anatomical preparations. Of that letter I applied for a copy, and it is to certain parts of that letter that I mean to call your attention; your name and mine appear together; Mr Beck's is opposed to both. I would much rather that all this had been delayed or deferred until the opinions of the Physiological Committee of the Royal Society be submitted to a higher authority—their judgment examined by a body of men who are not known to form committees, nor clubs, nor coteries, nor cliques—and their unjust decision for such it is no doubt—reversed. But perhaps it is right that I should notice this letter now when all the circumstances are fresh in my memory, my remarks will, I feel confident, satisfy you, and even Mr Beck himself, that it is utterly impossible I should have any wish to undervalue his great labours, or detract from the merit justly due to him.

Permit me first to observe to you that Mr. Beck's letter strongly resembles his dissection of the nerves of the uterus; all which it contains may be true, and probably is quite true; but it does not contain the whole truth. This is precisely the state of his dissection, with this addition, that many parts have been dissected in an unusual, if not in an inadmissible manner: lastly, claims are made to discoveries, which, in no shape, belong either to him or to those to whom the reporter or reporters of the Physiological Committee have thought fit to ascribe them. That I may put this matter in as clear a point of view as I can, I have requested the Editor to reprint Mr. Beck's statement with mine; it would give me great pain if I found that I hurt Mr. Beck's feelings or yours by so doing, thus losing the good opinion of two gentlemen whom I highly esteem; but I cannot persuade myself that this will happen. To those on the other hand, who, to gratify the malignant feelings of one whose name does not appear *as yet* in this controversy, but who, notwithstanding, is the prime mover of all this vile display, have pledged the respectability which belongs to their status,—a responsibility attaches, which the profession may one day visit on their heads.

A considerable time (some years) ago, I examined the original dissections of the nerves of

the uterus by Dr. Lee, quite aware that the accuracy of these dissections had been disputed by many excellent anatomists; amongst others, by one whom I am proud to say I educated, and with whom I have been in constant friendly relation for at least twenty years—Mr. John Goodsir, of Edinburgh.* My report, printed in the *Medical Gazette*, on Dr. Lee's dissections, was very brief they appeared to me sufficiently accurate. The increase in the size of the ganglions and nerves in the impregnated uterus, was, I thought, to a certain extent, more apparent than real, still it existed. This was the substance of my original letter to Dr. Lee, written some years ago. Now when I had the pleasure of meeting you at the table of our mutual friend, Dr. Hodgkin, these things were talked freely of; you knew my former opinions and you very naturally said, "you had better see Mr. Beck's dissections." "Most assuredly" was my reply, provided there be no objection on the part of Mr. Beck himself." After hearing from you that Mr Beck would, you were sure show me his dissections with very great pleasure; that he courted, rather than shunned, a full inspection of them by anatomists, I accepted this shall I call it friendly, challenge, to correct my former opinions.

Now my dear Mr. Bowman, this was not all our conversation at the hospitable and kind table of our much esteemed friend, we discussed other "nervous dissections," if I mistake not, at the same time, and it was here that you mentioned to me "*a peculiarity* in Mr. Beck's dissections, which rendered more than doubtful the existence of the greater part of Dr. Lee's preparations of the nerves of the uterus."

I have now, I think, disposed of Mr. Beck's objections to the word "challenge," let us by all means say, invited me to correct my former opinions; this, no doubt, is the proper word, and the one which Dr. Lee would use were he rewriting his correspondence; a challenge is "a defiance" in one sense; now, you could not give this for more reasons than one, but especially *for this one*, that you yourself entertain great doubts of the *absolute correctness*, of either dissection. my own feeling is, that were we to go over these preparations again we should *easily agree*; but to return.

We proceeded to Mr. Beck's house on the day appointed, Mr. Fergusson accompanying you; what that gentleman's opinions are will appear in due time; he made a shrewd remark to me, worthy of his reputation as a most acute and practical observer, and minute anatomist; all this may appear in due time, but it is clear that in a controversy of this kind it is not warrantable to draw into it the names of gentlemen to whom ultimately the whole matter of dispute may be referred—yes, referred - for it cannot rest here. Allow me to examine these dissections in presence of Messrs Fergusson, Stanley, Granger, Lane, Lawrence, Willis, and Liston—any one of whom, by the extent of his practical anatomical researches is perfectly competent to decide on this matter without the aid of another—and I will undertake speedily to put an end to this controversy; but I will have nothing to do with persons who owe their reputation, such as it is, to position, to management, to political influence, who, when a new idea is started by a continental writer throw themselves, *con furore*, as an Italian would say, into it—appropriate it to themselves -place the names of the original discoverer either in an obscure foot-note, or speak of him merely in connexion with some trifling error of detail, which they claim the merit of correcting; neither do I choose to refer any such matters to men who write of anatomical discoveries, and yet cannot recognise the great hypogastric nerve when shown them. During the course of my examination of Mr. Beck's very beautiful preparations, every assistance was offered me by that gentleman; I feel greatly obliged to him for his courtesy and kindness. The conversation was, of course, an interrupted one; it amounted nearly to this:—

I. The tissues of the uterus had been but little opened into by Mr. Beck; when separated somewhat by myself numerous filaments might be seen which much experience convinced me were nerves Mr. Beck's offer to submit any portion of these filaments to high microscopes I declined. For this there could be no occasion with structures which I could make out, either with the unaided sight or with the very feeble hand-glass you saw me use.

II. I remarked to Mr. Beck that the *scarcity of nerves* in his dissection following the course of the arteries or vessels *surprised me*. I told him I was not altogether prepared for this, admitting, however, that many years ago I had myself made out on the heart of the seal the fact, that many nerves proceeded to the fibres of the organ in that animal which did not in any way follow the course of the vessels. Still the comparative scarcity of such nerves in his dissections surprised me.

III. By opening the sheaths of the nerves to such an extent as Mr. Beck has done, the nervous character is apt to disappear and to be confounded with the cellular tissue; under this mode of disection ganglions assume a new form · the grey matter is scraped away, and what appeared a single ganglion becomes a group of ganglions marked by plexuses of a peculiar character, and such as I had not seen before; these remarks were certainly made in Mr. Beck's presence, for he observed to me that these were very peculiar and "unlike what occurred in other parts of the "body," perhaps I ought to have said that to me they did not seem to be plexuses at all; but I should have been acting contrary to my nature to have entered on a controversy in the house of a gentleman, who had behaved in so liberal and straight forward a manner to all Besides you must know well, although the Physiological Committee does not seem to know it, that by a similar manipulation some years ago attempts were made to shew that many of the large ganglionic structures of the uterus were *illusory ganglions*, that is, were composed of several smaller ones, united, not by plexuses, but by numerous communicating filaments. Surely this fact cannot be new to all the members of the Royal Society.

IV. You called my attention especially *to a remarkably long nerve* running down the front of the uterus, the course and presence of which rendered, in your opinion, the great portion of Dr. Lee's dissection doubtful. It sent off you thought, no branches; it received, in your opinion, no communicating filaments throughout its length and course; to *this nerve* you especially called my attention. Mr Beck was present during the whole discussion regarding this nerve.

1 I remarked to you that this nerve was not of uniform strength, *but tapered*, now you admitted immediately that *it tapered*. But nerves which *taper* give off branches, *ergo*, this nerve must have given off branches originally, but no such are now to be seen, *ergo* they must have been cut away.

2. I next remarked to you that it *tapered* unequally; that is, that it must have given off nervous filaments and received others. I showed you *two branches* which must have been *cut across* during the dissection; the portions were still left attached to the pretended *long nerve*, or rather, as I would call it, *superficial plexus* and the other ends of the divided branches were lying close by in the tissue of the uterus. You immediately examined those two divided branches, and told Mr. Beck that he must admit them to be so; Mr. Beck's answer was, that if I would raise up the portion in the uterus he would immediately test it with the microscope. The agreeing to such a proposition would precisely have been a [illegible] to the examining of one of the ends of [illegible] which had been cut with the scissors in my presence in order to ascertain whether it was the same string or not; I know not what you thought of Mr. Beck's proposal. I of course took no notice of it.

IV. I soon after shewed you two other branches which had been cut during the dissection: fancying that you were not so fully satisfied with them I took the liberty of shewing you that the nerve varied in thickness at these *additional points*, and that filaments lay beneath corresponding to the divided branches. I think it was soon after this that Mr Beck left the room for some time; I think he felt that he had lost your support on a most important point; with respect to our further conversation the public has nothing to do; you being associated with those of whom St. Paul says, "there be some who gaze dimly through darkened glasses," in no shape detracts from your high merit as an observer. It has always afforded me the highest pleasure to converse on scientific matters with persons like yourself and Mr. Beck; the few who desire "to know the unknown" are persons with whom I particularly dislike to have any controversy; literary and scientific pirates I abhor and detest; I believe they know it to be so, and thus no love is lost between us. Mr. Beck and his friends attach much importance to the opening up the sheaths of the nerves, separating their component fibrils, dissecting the ganglions so deeply as to remove in as far as possible all that is not nervous matter, now, there can be no objection to this, as an object of closet inquiry; but in the first place, the method is *far from novel*; and in the second place, it is difficult to see where it is to end. In many parts of the body ganglions considered as single, are readily resolvable into two or more, by dint of scraping. The superior cervical ganglion itself, on being treated after this fashion, occasionally assumes the form of three or four distinct ganglions, perhaps it really is an aggregate of so many ganglions, representing the number we ought to find in correspondence with the uppermost cervical vertebræ; philosophic anatomy warrants a view of this kind, but still, for all practical purposes, the superior cervical ganglion had better be described as one. Microscopic anatomy is unquestionably, like transcendental anatomy, a valuable instrument of research; in the meantime, their misapplication has done much mischief in the medical educational institutions of the metropolis I have seen numbers of medical men and students "peering dimly through glasses," whom I could not persuade to learn correctly the exact descriptive anatomy of any organ of our frame.

In conclusion, I am free to admit that I have with the greatest reluctance engaged in a controversary, in the conducting of which by one party at least, it is evident that the scalpel and common sense have been abandoned for the pen and the microscope. In a struggle like this, the practised -I might almost say the thorough hack—is sure to have the best of it. Compilers, par excellence, who so dexterously interpolate the deep researches of continental writers and discoverers, with their own crude, closet conjectures and comparisons, as to render it difficult to discern the source whence such labours have come; who shift the pen for the scissors, and vice versa, with such consummate skill, that the result is a highly finished and glazed mosaic carpenter work, calculated to deceive any one but those who know them well from their earliest flights; with such persons, I repeat, I much hesitated to enter into any controversy. What I have stated is so simple in itself, so plain a matter of fact, that I trust I may avoid all pen and ink conflicts. [illegible] appeal to the inspection of the structures, where I trust to be as much [illegible] as any of the disputants. Of the insinuations thrown on against some members of the physi[illegible]rical [illegible] mittee, of their having engaged Mr. B[illegible] secute this enquiry, for the purpose of in[illegible] Lee's reputation I [illegible] remark, that supposing [illegible] correct, I cannot [illegible] how they in any way [illegible] the merit due to Mr. Beck, for his untiring [illegible], for [illegible] dexterity, for his love of science, [illegible] time, believe these insinuations to be well-founded.

* [illegible] a singular circumstance, a knowle[illegible] of which I owe to Dr. Lee, that my esteemed friend Mr. Goodsir pronounced against the accuracy of Dr. Lee's dissections without having seen his preparations

HOSPITAL REPORTS.

GLASGOW ROYAL INFIRMARY.

Reported by WALTER BAIN, Esq

DIABETES MELLITUS, PHTHISIS. RELIEF.

James Cowper, aged twenty-four, a Scotch sailor, unmarried, was admitted into the Glasgow Royal Infirmary, March 14th, 1845, under the care of Dr. Watson.

The patient complains of great thirst, copious discharge of urine, cough, and expectoration.

His urine resembles water in appearance, is of a sweet taste, its specific gravity 1044. Appetite moderate; tongue white; gums red, soft, and bleeding readily on pressure. Bowels regular; skin soft but dry. Nails convex. Pulse 104. He is much annoyed with flatulence after taking food, and his cough is worst in the morning. Breathing easy. The percussion sound under the right clavicle is duller than that under the left, over rest of chest it is natural.

Under right clavicle respiration is rough, and vocal resonance is increased. Over the left side of the chest there is much soft crepitation, and in the axilla some gurgling. Respiration over the left scapula harsh, and vocal resonance more intense than natural.

The patient is of tall stature, thin, but muscular; his cheeks are sunken, but he looks well

He has been much abroad, and in all climates, and he attributes his illness to variations of temperature. He has been ill for eleven months, great thirst being his first symptom. He first observed his urine to be sweet ten weeks ago, and about the same time the cough began to annoy him much. He is not aware of the nature of the diseases of which his relatives have died.

To have milk diet, ad libit, with four eggs four times a-day.

21st. He wishes to go home.

Dismissed.

DESTRUCTION OF FOREARM, COMPOUND FRACTURE OF LEG, PRIMARY AMPUTATION OF ARM, PNEUMONIA—CURE.

Alexander Thomson, aged twenty-nine, Scotch engineer, unmarried, was admitted into the infirmary, May 27, 1845, at half-past five, p.m., under the care of Dr Laurie.

Two hours previously, while at work near the fly-wheel of a steam engine his right fore-arm was caught between two toothed wheels, and he was carried several times round with them.

On admission, the right fore-arm from the fingers to the elbow was found to be reduced to a jelly.

Both bones are fractured, comminuted and deprived of periosteum to a great extent, the integument and muscles are completely destroyed, and no arterial pulsation can be detected below the elbow.

The left tibia is fractured obliquely about two inches from the ankle-joint, and there are two small wounds in the integument about three-fourths of an inch above, and communicating with, the fracture. Fibula uninjured. The limb is swollen and tense as far as the knee. The patient has lost much blood from the injured extremities, but all hemorrhage has now ceased. His face and lips are pale; and his extremities cold. Heart's action feeble. Pulse 70, weak. He has has had some retching and vomiting.

Adhib. sinapism epigastr. Warmth to extremities.

8, p m. The patient has rallied considerably. On consultation, amputation of the right arm at its lower third was unanimously recommended. Leg to be dressed with a wet Scultetus' bandage, and lateral splints.

The operation was performed at half-past eight as recommended; the patient bore it well.

Hab. in dies Vin rubri., ℥iv,; omni nocte Pulv. opii, gr ij.

29th. The patient has rallied completely; pulse 100, of good strength. Stump and leg perfectly easy. Ordinary Diet.

Contr. omnia.

31st. The patient is much the same as at last report. Stump to-day partially dressed, looking well; leg easy, also doing well

Contr.

June 2nd Augeat. vin rubr. ad ℥vi., in die.

Contr. opium.

5th. Stump repeatedly partially dressed. Portions of sloughy cellular membrane removed; going on well. Leg still continues easy.

Contr.

9th. The stump was fully dressed to-day; part of the flap was sloughed, otherwise looks well. The leg was also examined to-day, and a large slough was found on its inner side over the fracture. Has never complained of uneasiness in seat of slough, and has none now. Pulse 90, of good strength.

Contr.

22. Stump nearly healed; sore on leg pretty large, but granulating well. Union of bone commencing. Limb put up with a dry, many-tailed bandage, pillows, and lateral splints.

Contr.

July 3rd. The patient went on favourably till two nights ago, when he had slight feeling of cold, followed by heat and feverishness. At present his face is flushed and countenance somewhat anxious. Pulse 110.

On dressing the stump, a small abscess was detected in the axilla, which was opened; the bandages were removed from the leg, which is looking well, and healing rapidly. Bone pretty firm.

Contr.

4th. The patient has this morning severe pain, preventing deep inspiration, along lower part of both sides of chest. In both situations but especially in left, fine crepitant râle is heard at the termination of inspiration. Some cough, with rusty expectoration. Pulse 120, sharp.

Pectori adhib. sinapism. amplum et postea cataplasm. emollient. Milk diet. Omittr. omnia.

℞ Calomel., gr. ij.; Opii pulv., gr. ss. M.

Fiant pulv. tal. xij., quorum sumat, j., quarta q. q. hora. Hab. vin. rubri, ℥iv

5th. Pain in the chest relieved; lungs more completely filled during inspiration. Crepitation less extensive. Pulse 114. Tongue clean. Bowels confined.

Contr.

6th. Pains still easier. Pulse 108. Tongue cleaner. Bowels opened.

Contr.

7th. Pulse nearly the same. Pain easier. Crepitation still heard on left side. Mouth a little sore.

Sumat pulv. sexta, q. q. hor. tantum.

8th. Still pain in side.

Lateri impon. vesic. modic.; post. cataplasm.

Contr. pulv.

9th. Pain rather relieved. Bowels loose.

Pulv. singulis add. tinct. opii, ♏. x.

10th. The patient had a slight chill last night. Pain the same. He perspires about head. Pulse 120, feeble.

Hab. vin. rubri, ℥vi. in die.

11th. he has had no return of rigor. Pulse 115, more firm. Mouth decidedly sore.

Sumat pulv., j., vesp. tant.

15. He feels pretty comfortable from the time he awakes in the morning till half-past one, p.m., when he becomes feverish. Pain of side less. Percussion dull still. Respiratory murmur deficient, and crepitant râle still audible.

Rept. vesic. lateri dextr., sumat pulv. mane et vesp; Minuat vinum ad ℥iv.

17th. Chest and respiration little changed. Yesterday pain and swelling of wrist and fingers came on. Granulations of leg have sloughed and separated. Sore now looks clean.

℞. Sp. æth. nitros., ℥iss.; vin. colchic., ℥ss. M. Sumat, ʒj bis in dies ex aq.

Foveat carp. et man. Contr. vin. et pulv.

21st. The pain and swelling of the fore-arm are better. Pulse 108, intermitting every ninth beat. Percussion and respiratory murmur improved on both sides anteriorly; behind not examined. Tongue white. Sensations less comfortable. More feeling of debility. Bowels loose.

Pulverib. sing. add. opii pulv., gr. j.

Contr. alia.

29th. He was to-day turned on his left side in consequence of threatened bed sores. Right side of chest now clear anteriorly; dull posteriorly. Crepitation and bronchial respiration in latter situation. Pulse 108, of good strength, now regular. Tongue pretty clean. Cough increased. Bowels loose. Pain and swelling of fore-arm gone.

Omittr. pulv

℞. Hydriod. potass., ʒj.; Aq. distill., ℥xiv.; Tr. opii, ʒij. Solve. Sumat ʒj. ter in dies.

Contr. vinum et hab. in dies. Cerevis fort. ℔j.

August 9th. He continues to improve. The sore on his leg is healing. He got up to-day for the first time.

Omittr sol. hydriod. potass.

September 8. In every respect well.

Dismissed.—Cured

The patient showed himself at the Infirmary in the beginning of October, at which time he had quite recovered from the effects of his serious accident.

URINARY INFILTRATION, PERINEAL ABSCESS FROM RUPTURE OF STRICTURED URETHRA —RECOVERY.

Wm Morrison, aged forty years, Scotch weaver, married, was admitted into the Glasgow Royal Infirmary, July 28th, 1845, under the care of Dr Hannay.

The patient has been of very intemperate habits for many years, and fifteen years ago he contracted venereal disease since which he has always had difficulty in voiding urine, and occasionally after exposure to cold or intemperance, he has suffered from complete retention

He has never had any treatment, and he says, when retention has come on, he always succeeded in relieving himself by the application of hot fomentations to the hypogastrium and perinœum

Three weeks ago he had an attack of retention to overcome which his usual remedy failed, and after suffering great pain a swelling formed in the posterior part of the scrotum and gave him relief He was pretty well for a few hours after this, but soon felt a tingling heat and pain about the perinæum The swelling afterwards burst and gave exit to a considerable quantity of matter and afterwards to urine

On admission, a large sloughing cavity was found to exist in the back part of the scrotum which was swollen œdematous red and painful Walls of cavity were of an ash gray colour, extremely irregular, and discharged a fœtid pus with a highly urinous odour The hypogastric region was swollen, red, tense and painful from the pubes to the umbilicus, and from the crest of the ilium on one side to the corresponding point on the other The swelling felt hard and boggy, and at one or two points decided fluctuation could be felt

Catheterism with instruments of all sizes, metallic and gum elastic, has been attempted in vain A large instrument detects a long stricture about three inches from urethral orifice The smaller instruments pass down to the triangular ligament but no farther The catheter when in the urethra, can be touched by a probe introduced into the cavity in the scrotum, but neither can be passed thence into the bladder The middle lobe of prostate gland is much enlarged

The patient is very feeble Pulse eighty-eight weak Countenance sharp and expressive of irritation

Sounds of chest are normal, abdomen natural Tongue clean Bowels open

Incisions were made into the swollen parts of the abdomen, and afterwards fomentations were applied

30th Several incisions made through the swollen, red, and tender skin in the left iliac region, giving vent to a small quantity of buff coloured curdy like pus and much blood The hemorrhage was immediately stopped by plugging with lint

The urine flows freely by the perineal fistula, some also escapes by the natural passage Catheterism was again tried in vain Constitutional symptoms moderate Bowels not opened since admission

Hab stat ol. ricini ℥ss et injiciat vesp enema domestic Hor Somni hab haust, c tr opii m xx Ordin ry diet

August 1st Erysipelatous redness and swelling at the lower part of the abdomen is considerably diminished Another incision made to day, gave exit to the same kind of matter as before, the patient has passed a good night Constitutional symptoms moderate

Hab tr in die camphoræ gr v, pulv opii gr. ii

2nd The discharge from the incisions is more healthy. The skin over the hypogastrium is stil red and swollen, but less painful The urine is freely discharged by the aperture in the scrotum which also looks more healthy Pulse 96 small Contr Pulv.

Hab in dies vini rubri ℥vj, Admov cataplasm emoll hypogastr

5th. The skin over the lower part of the abdomen is less swollen, there is a considerable discharge of healthy pus The scrotum is stil swollen and painful General health improves.

Hab suspensor Contr omnia

The suspensory bandage, has given much relief The cavity in the back of the scrotum is granulating well, and has contracted, much urine still flows by the fistula The lower part of the abdomen is now nearly well, and the patient feels much stronger, and takes his food well Contin vinum rubrum pulv. vesp tant.

12th He is improved in all respects and to day a No 3 catheter was passed into bladder, and allowed to remain for a short time Contr. omnia

21th The swelling, redness, and pain in the hypogastric region are nearly gone, no sloughs have come out of the incisions The cavity in the scrotum is healing rapidly Catheters have been regularly passed since last report and now the patient voids nearly the whole of his urine by the urethra Contr omnia

28th A full sized instrument can now be passed into the bladder. The lower part of the abdomen is now well, save a small ulcer over one of the incisions The cavity in the scrotum is nearly well but there is still a fistulous opening into the urethra The patient wishes to go home Dismissed

THE MEDICAL TIMES.

SATURDAY, AUGUST 15, 1846

Perhaps after all there is no better friend to Conservatism than your ultra con Radical Snob When a man preaches to you that all noblemen are tyrants, that all clergymen are hypocrites and liars that all capitalists are scoundrels banded together in a conspiracy to deprive the people of their rights he does less wholesome revulsion of feeling in favour of the abused parties the reverence of fair play leads the generous heart to take a side with the object of unjust oppression

For instance although I hate military flogging the most brutal and odious relic we have left of the wicked torturing old times and have a private opinion that soldiers of crack dragoon regiments are not of necessity the very wisest of human creatures yet when I see QUACKLEY the Coroner giving himself heroics of patriotism and attacking the men for the crime of the system (of which you and I are as much guilty as COLONEL WHYTE unless we do our utmost to get it repealed) I feel myself led over to the brow beaten side and inclined to take arms against QUACKLEY Yesterday, a fellow was bawling by my windows an account of the trial at Hounslow, [illegible] [illegible] brutal and savage Kurnal [illegible] for the small charge of Wun Apny" *Was that fellow a ... patriot think you or a Radical Snob, and ... the wanted to put down flogging or to get ... ?* Punch, (*article Snobs of England*) Aug 8

WHEN we branded the judicial actings at Hounslow as a disgraceful abuse of an important magistracy, we promised early to resume the evidence in support of our opinion We meet however, some peril in performing the duty "Coroner Quackley" has formally suspended over our heads, the *lash* he deals in—"the law." The maladministrator of justice at Hounslow becoming the abuser of parliamentary privilege in St Stephen's, has publicly threatened private litigation, as the penalty of public discussion. He has "instructed his solicitor"—so he assures the Commons—"to file a criminal information" against us, for analysing—consistent liberal!—*his* doings! We smile at the menace, respecting no more the *exparte* threats and abuse of the indecorous senator than the *exparte* proceedings of the undignified coroner Be the law used or not we shrink not from our duty. At any risk and at any cost we will perform our pledge of holding up to the just rebuke of that efficient tribunal, public opinion, the curious idiosyncrasy in an English magistrate, which can turn a *medical* Coronership into an agency for professional degradation, extract the materials of judicial buffoonery out of the tragic incidents of a supposed assassination, and prostitute the most sacred uses of justice to the emergencies of political faction.

A fact to start with, which of itself gives the measure of this inquest's worth, is that the *medical* verdict of this jury, GUIDED by a *medical* coroner, is beyond all question *medically* false Poor White did not die of the lash, and there was not a scintilla of scientific evidence given to suggest that he could Every statement of Mr Wilson to that effect is not only suspicious and unproved, but actually *absurd* First The "be all and end all" of his scientific nonsense is a "*ruptured* muscle All his statements and theories, and "discoveries" depend on a "*rupture*" Is the rupture then visible to the naked eye or through the microscope? No It is not even pretended The assertion on which all rests is, after all, but a *supposition!* What is there, therefore, in favour of this strange supposition? How is the extraordinary fancy supported? Oh, a "*part* of the *lowest* line of muscles, about three inches in length, (*name* not given!") by *about* one inch and a half in *greatest* breadth, between a quarter and a half inch in thickness, and lying in contact with bones" was "disorganised," was "soft," was "pulpy!" So much for the proof of a "rupture"!" But then this patch of softened muscle, supposing it worth anything, is not detected during two post-mortem examinations, though conducted, the one by a party of three, the other by a party of two, surgeons—is not detected either by Mr Wilson, except during the forcible exclusion of the three surgeons most interested in seeing it if it could be shown, and finally, is not detected till seven days or more after the former post-mortem examinations, and till the *twelfth* day after the death, when, through the extreme heat of an extremely hot summer, the "softening" agency of decomposition has been allowed full time for doing its worst! In other words Mr. Wilson swears that the man was *killed* under medical surveillance, because, thirty-seven days after the flogging and twelve days after the death, the putrid body exhibits a patch of decomposition in a small "part

of the deepest line of a "*nameless*" muscle! It is quite true, indeed, that the man died, by the admission of all, of acute disease of the chest, to explain which there existed an extraordinary change of temperature; it is quite true that there was an effusion of serum in the thoracic cavity that the pleura costalis and pleura pulmonalis were joined together by coagulable lymph, and that all the indices of a recent violent inflammatory action were demonstratively present; it is quite true, too, that for days after the flogging and before the supervention of this acute disease, the poor man felt well, moved freely, and even worked in a stooping attitude, without any inconvenience from the disorganised state of this magically potent muscle, communicating with the pleura! It is quite true, moreover, that the muscles directly exposed to the lash, the muscles which cover and protect the supposed seat of disease, and which would have been necessarily the centre of spasmodic action if there were any, were "unruptured," untouched, nay, perfectly healthy; all this is quite true, but, nevertheless, as the small patch of pulpiness, by a bare possibility, might not be decomposition; as, by a bare possibility, it might have existed before death; as, by a bare possibility, it might have existed from the time of the flogging; as, by a bare possibility, it might have originated in a rupture; as, by a bare possibility, (at least in Mr Wilson's creed), it might have caused acute pleurisy and pneumonia,—this worthy gentleman—as the Coroner's perambulatory witness—could not hesitate to swear positively, against five positive medical opinions, that the flogging killed the man! In precise proportion to the difficulty of believing his *hypothesis* was his positiveness in swearing to it as a *fact*. The more absurd the fancy the clearer Mr. Wilson's affidavit: nay, so decided is his scientific *clairvoyance* under oath on such points, that he is not only sure that a "ruptured muscle"—received in flogging, too—killed the man, but that without that "rupture," nay, without that flogging, he would not have died of anything else! During twenty-seven days White was under a fatality to die of *nothing* but the lash!

Mr. Wilson's pulpy softening, and ecchymosed condition have their seat in some small muscle or muscles very indistinctly referred to. Now to us it appears more than strange that any practical man should expect that these small muscles could present a perfectly natural appearance in a subject which, during the lapse of several days, lay on its back under an almost tropical heat, manipulated in several autopsies by different persons, and subject to that well known law and source of error to unexperienced pathologists—the gravitation of blood to the depending surfaces, reddening even to a purple colour every part, from the cutaneous surface to the deepest tissue of the bone. We defy any one to proceed with such deep dissections, to remove four layers of muscle in succession, to carry a saw across the laminæ of the vertebræ, necessarily touching several of the pedicles known to abound with blood, and to say that a small ecchymosed spot found in the lowest layer—adjoining the bones cut through—seated in an almost tendinous muscle—a muscle rarely or never used after the period of manhood and not even demonstrated as a distinct muscle in any anatomical school in London—owed its origin to a cutaneous sympathy with so remote an event as the flogging—a sympathy which like the electric spark, becomes visible only at the two extremes of the poles, neither touching nor affecting the intermediate structure.

Every anatomist, perhaps,—if we except Mr. Wilson—is familiar with the fact that at all seasons, but still more in an unprecedently hot summer, the progress of decomposition in the human subject is frequently accompanied with the rupture of blood vessels, which pour their contents into the surrounding cellular membrane. Such extravasations meet us even in our daily animal food, in which the mode of death has expressly in view the draining the flesh of its sanguineous fluids, and there can be few cooks who have not, in hot weather, had ocular evidence that a muscular joint, especially if unprotected from decomposition by the process of cookery, will exhibit this "*putrilage*"—as the French term it—diffused through the membranous interstices of the muscles, accompanied by a state of decomposition, in the tissues the muscles themselves, under the form of a sanguineous jelly, more or less offensive to the senses. Now, it is clear, by Mr. Wilson's own testimony, that to a limited extent this extravasation and decomposition had taken place in and around the muscles; and it is by no means improbable, although of course it has been overlooked by Mr. Wilson, that the effusion in the first instance may have been partly or wholly derived from the vessels of the theca spinalis which we may safely infer from the accounts given, to have been congested as might indeed have been anticipated from the drunken habits of the deceased. It cannot be doubted, too, that the osseous structure of the vertebræ, naturally filled with venous blood, (in this respect resembling the cranium) would, on application of the saw to the *laminæ* of the vertebræ, pour out its fluid into the structure of the multifidus spinæ, (the muscle crossing the plates of bone implicated in the dissection), and thus cause that appearance of ecchymosis so prominently dwelt on in Wilson's post-mortem report. Such effusions are the well known agents that lend activity to decomposition, and they exhibit themselves in three stages or degrees—ecchymosis, or simple redness from turgescence of blood vessels, effusion from rupture of these vessels giving forth materials readily to be decomposed—and *putrilage*, when the decomposition invades and takes possession of the surrounding tissues. But between these cadaveric phenomena, which are simple, constant and universal, the never absent characteristics of animal putrescency—which Mr. Erasmus Wilson could not have failed to find in White's case if he had tried—between these phenomena and the vital physiological effects of flogging inflicted twenty-seven days before death, where is the affinity? On what possible ground can Mr. Wilson withdraw these well-known results from the causes to which they naturally belong to transfer them to a remote incident with which no connection, pathological or anatomical, can be established? Need we here pause to ask the Profession was ever mention before made of so extraordinary a pathology? What will be the feelings of the real anatomists of Europe when they learn that such anatomy and such pathology is taught in a London Hospital School? What will the medical *jurists* of the continent say when they learn that English magistrates have at call advertising anatomists, formerly their office clerks, ready to shape scientific evidence, after this extraordinary fashion, even when the reputation, and liberty and life of honourable men are at stake!

For our professional readers it must be a work of supererogation to point out Mr. Wilson's defective descriptions of the results of the autopsy. We have no hesitation in affirming most advisedly, and challenging for the fact any legal investigation Mr. Wilson may deem safe, that he could not have understood the elementary anatomy of the structures he professes to have examined. What *other* anatomist could have submitted to the public and profession a report so vaguely couched in support of a pathological discovery so extraordinary itself, and so grave in its possible results? We find it difficult to conceive how so many errors could have been crowded into so small a space, and yet allow room for at least half a dozen unscientific and irrelevant clap-traps, having no other object but to assist his friend Coroner Quackley in exciting popular feeling. In the face of extensive diseases of the thoracic viscera, he admits that his attention was "especially directed to the back and spine" in his post-mortem examination of the deceased. What is this but coming to the autopsy with the understanding that it was his business to find the cause of death in these regions? Are we then not prepared in advance to find that the foregone conclusion will be supported by any pretence, however flimsy, even if it exposes him that uses it, to the peril of standing to the nonsense as a scientific discovery? Can we be amazed that from the first instant of the enquiry he sets himself up in direct opposition to the five medical men that had preceded him? Is it extraordinary that in an elaborately got up document he uses language the most vague and indefinite to cover the insignificant pettiness of the grounds on which he proceeds? or that, driven by his very commission from the well-ascertained facts of sound pathology and physiology, he should seek, in some impossible and inconceivable action and change of structure in living fibre, those opinions which alone could answer the objects of his Coronatorial patron, and give efficiency and note to his own medico-legal evidence? In one word, from what other anatomist, or pathologist, or surgeon, in any *other* position, could the public have received such a post-mortem report as the following:—

"On raising the muscles, or flesh, from off the ribs and spine, I find a part of the deepest line of muscles, viz., that which lies in contact with the bones, in a state of disorganization, and converted into a soft pulp; in medical language, I should call this a pulpy softening of the muscles. The seat of this pulpy softening was the sixth

and seventh ribs, near their attachment to the spine, together with their intervening space, and the hollow between the sixth and seventh process of the spine. The extent of the disorganization was about three inches in length by about one inch and a half in greatest breadth and between a quarter and half an inch in thickness. In the space between the ribs the muscles had undergone this pulpy alteration, even so deep as the lining membrane of the chest, the softened muscles being in absolute contact with the lining membrane, that portion of the flesh which occupied the groove of the spine and had undergone a similar disorganization, was one of the little muscles known to medical men under the name of the multifidus spinæ. In addition to softening of this little muscle it was partly surrounded with blood. It was in a state medically called ecchymosed.'

We might leave such a description, and by an anatomical lecturer too, in the hands of the profession, without one word of comment. How peculiar the technical language! "A part of the deepest *line* of muscles, meaning *layer*, no doubt; that which "lies in contact with the bones, in a state of disorganization, and "converted into a soft pulp," a pulpy softening of the muscles"! There is no name—no description of the muscles. All is careful confusion and elaborate perplexity. Words are used to conceal ideas. Why is there no description of the spinalis dorsi? of the semi-spinalis dorsi? levatores costarum? of the external intercostal? What was the condition of the tendinous portion of the longissimus dorsi and sacro lumbalis—muscles above all others most exposed to the immediate action of the lash, and to convulsive action had there been any? We are told that "the seat of the pulpy softening was the sixth and seventh ribs, near the attachment to the spine." Is it meant that the ribs were *softened*? The language employed excludes any other meaning. We are again told that the pulpiness was "*near* their (the ribs) attachment to the spine." But as the ribs are attached by two points to the spine an inch apart from each other, we are entitled to ask, did Mr Wilson mean both attachments, or was he ignorant that there was more than one? Now, at and between these attachments the ribs have no connexion with the muscles spoken of. Nay, they are absolutely disunited by a particularly strong plate of bone, formed of the transverse process of the vertebra and its pedicle, interposed between the rib and the multifidus spinæ. Mr Wilson then adds the unintelligible phrase "together with their intervening space." We are anxious to know to what "intervening space" he alludes. Does he mean the intercostal space, external to the tubercle of the rib? But the multifidus spinæ does not lie there, and if such be the locality of that muscle in Mr Wilson's science, we wash our hands of this worthy lecturer on anatomy. The character of the profession itself would suffer by the needless exposure of such enormous ignorance. But, if he mean the space between the transverse processes of the vertebræ, he might surely have said so, but such a declaration would have been inconvenient—it would have tied the coroner's witness down to the multifidus spinæ, and would have precluded the necessity of *dragging in* or introducing a portion of the intercostal muscles.

The part which the "intercostals" are thus made to play, suggests the reflexion that one discovery is as much of calling for the backing of another as one lie, according to Goldsmith, is certain of drawing ten more after it. The first *discovery*, made too under the patronage of a *medical coroner*, is that a small *portion* of a muscle, whose action is instinctive, instantaneous, and entire, took on a convulsive action in opposition to the physics of respiration! The thing wanting was an explanation, which should trace the "pulpiness" home to the "convulsive action," and through that to the "flogging." Hence, *discovery* No 1. But *discovery* No 1 begot a new difficulty, to obviate which we have DISCOVERY No 2. For what—people asked—became of the corresponding muscle of the other side which must have undergone precisely the same amount of action? This was an obvious question, that the difficulty would have occurred to any one, always excepting, however, a *medical coroner*. We have, therefore, now DISCOVERY No 2, that two muscles, which all the world believed to act in unison, become, in this particular case, disassociated, and acted separately! But there was a third need, that of connecting the pleura with the diseased muscle. Hence DISCOVERIES No 3 and No 4. DISCOVERY No 3, that the small portion of the intercostal in immediate contact with the pleura! and DISCOVERY No 4, what we have already adverted to, that the *multifidus* spinæ, in a state of pulpiness, could influence, by contact or sympathy, the organ occupying a cavity separated from them by a massive column of bone! But the crowning discovery, DISCOVERY No 5 in the series, which must for ever establish this model lecturer's fame as the COLUMBUS of medical science, is, that the pulpy disorganization of the muscle, and with it the simple pulpiness—the acute inflammation of the thoracic viscera—took place precisely on the side least injured by the corporal punishment! We are aware that a blow on the right side of the head will give rise to paralysis of the left side of the body, and vice versa, but till the brilliant imagination of our modern anatomist had taken its full swing, we were wholly ignorant that a scourging on the right shoulder may be followed by a pulpy softening on the left side of the spine, having for effect acute inflammation of the thoracic viscera in the same region! But there is one fact recorded we will not contest; one item of this *lecturer's* anatomical science that *will* pass muster. The nerves, the organs of sympathetic action in the midst of all these crossing sympathies, and although the surrounding muscles were "*lacerated*," "ruptured," "disorganized," and affected with pulpy softening, "presented a healthy appearance"! Everybody knows that he is candid enough to tell us that the healthiness of the nerves does accompany the advanced stages of decomposition; that anatomists desirous of effecting clear and rapid dissections of the nerves, avail themselves of this well known law; and the only wonder is that a medical coroner and his "celebrity of anatomical science" should, with such self-evident and damning disproof before them palm off on an ignorant jury, as a discovery the natural and inevitable effects of cadaveric decomposition, as the results of mysterious vital phenomena!

To illustrate the scientific tendencies of this question we will just suppose Mr Wilson's course of action applied in another case. A patient labours under acute rheumatism. A blister has been applied between the shoulders by some professional opponent of the *medical* coroner. In the ordinary course of rheumatic affections, the disease seizes the membranes of the chest and heart. The patient, under violent change of atmospheric temperature, grows worse, and dies. Enter coroner's friend, Mr Wilson, the skin doctor, to make a post mortem examination, with instructions to direct his attention especially to the back and spine, five medical men having previously, on autopsy, certified positively that the death occurred from pleuritic inflammation. Not so, says Mr Wilson. My five professional brethren do not know their business. They have been long conversant, it is true with the application of blisters; and I admit that as yet I have not myself cognizance of the kind. But against their thirty years experience I set my *art* of making discoveries. The blister has a mysterious mode of action; few have guessed it. If it missed the first, and the second, and the third and the fourth, it seized on the fifth, or at all events on the sixth layer of muscles (minutiæ in such things are needless, or at least, inconvenient). These obscure muscles acted upon by still obscurer sympathies—the stronger because the further off—took on convulsive action; the convulsions produced "rupture" or "laceration" (the terms are synonymous); rupture gave rise to disorganization; disorganization to pulpy softening, pulpy softening to inflamed membranes, inflamed membranes (piercing a plate of bone) to pleuritic inflammation, and thus completing the circle of sympathies and reasonings, the blister killed the patient! Such is the reasoning of a medical coroner and his anatomical witness, a reasoning, which allowed or followed in *any* case of death occurring during medical treatment, would leave no practitioner, however skilful, free from perilous impeachment and loss of repute!

Long as have been our remarks, we cannot close this article without repeating, and, if possible, with more emphasis, every word of reprobation expressed in our former article on the judicial management of this inquest. We denounce the selection of Mr Wilson as a preliminary intimation of an outrageous partiality. His private intimacy with the coroner, though adroitly blinked to the jury and the public, was for years that of servant and master, mutual patrons and obligees. In any matter affecting the private or public views of his old employer, he was not an independent witness. The fact, too, stands undoubted that Wilson, as though he had secured the good-will of Wakley's medical fees at inquests, was the ambulatory surgeon generally called in by him, to the exclusion of the ordinary attendants, whenever professional testimony was required. The coronership, indeed, is a kind of partnership between them—its mileage fees going to

the coroner—its medical focus to his peripatetic *attache*. In other words the magistrate and the witness, like Peachem and Lockit, have a mutual interest in being good friend. Now, when three surgeons—two of whom were not implicated in the flogging transaction—had carefully made their post-mortem examination, published its minutes and given their decided opinion; and when two other surgeons, Messrs. Day and McKinlay, at the request of the coroner and jury had made a second post mortem examination, and overhauling the grounds of the former opinion, had given to it their deliberate confirmation; when five surgeons, differently placed, and carrying on their examinations under different circumstances had given a positive professional opinion, all in strict concurrence—we do say it was a gross libel on professional character, to scheme the contraversion of their united opinion by the testimony of one solitary explorer, set subsequently to make a new post mortem, and that it was perfectly outrageous that the [illegible] concocter of the affront should select for the purpose his own boon companion, [illegible]. The defence made that the [illegible] of the witness [illegible], even, *if true* would [illegible] in answer; for it [illegible] the part of a *medical* coroner to, without any shadow of ground [illegible] of the groundwork on which all [illegible] and character [illegible]. But we deliberately challenge proof that Mr. Wilson has established any claims to be acknowledged by the profession as distinguished either in anatomy or pathology. His "Healthy Skin" book is a work wholly popular in its character; and in its aims and tendencies [illegible], and we propose, in an early number, to show that his compilation [illegible] London lectures—[illegible] the medical science of our country. On no one ground, then, can we find the vestige of a reason for a [illegible] to the world, by the unsupported testimony of a private comrade, the mature convictions of five able and respectable surgeons!

[illegible] by the "*ill taste*" in *medical* [illegible] coroner and witness—of suggesting and submitting to so equivocal a step; passing by the stupendous [illegible] morbid animus of the medical Coroner who could listen with complacency and delight to the incongruous and ridiculous medical testimony purveyed to the jury by the gentleman they called their "*own doctor*"—passing by the unseemly exclusion of the medical witnesses during the whole of the first day of the inquest—passing by the [illegible] exclusion of Dr. Warren, when Erasmus Wilson, by *private* autopsy, was taking up in the putrid subject evidence which, unrebutted, might convict him of manslaughter, and the exclusion of Drs. Reid and Hall, whose professional character he had been *engaged* to undermine; passing by also, with many similar matters, the monstrous irrelevancies of enquiry and hideous buffooneries of expression and gesticulation that disgraced the judicial presidentship—let us be permitted to say one concluding word on the defence which this high minded and dignified Coroner made in the House of Commons when our accusations in a previous number were categorically read to him to the infinite satisfaction of his brother members. We own to a deep pity of the mental organization which could have set up such a defence. This hon. member of Parliament confessed that he had been compelled by us to go a begging from a poor attorney at Brentford for a certificate of his good conduct as an English magistrate, and the satisfactory "testimonial" was read to the House in due form and in all its plenitude. [illegible] that after such [illegible] humbleness, such [illegible] forcibly remind us of Newgate 'witnesses to character,' the honourable member should have exhibited the *spirit* and *good taste* of insulting a "*tupil Lawyer*," a minister connected with the medico legal department of this journal—[illegible] whom "*tupil*" he is—the *clever* [illegible] medical worthies, that "he hated of all the world the most, [illegible] It by [illegible] he means that sort of ability which can think it a triumph to fish out [illegible] of magisterial [illegible] "stroll" there [illegible] "*tupility*," which the Coroner thus [illegible] cultivates the better. But "Coroner Quickly" cannot but be at continue with truth [illegible] his conception of the cardinal qualities!

THE NATIONAL INSTITUTE.

Our readers will peruse with pleasure the details of the important meeting held on Wednesday evening. The harmony and general effect of the proceedings were most satisfactory; and we can not but augur the best results from so promising a commencement. All, however, lies in the hands of the profession. If they will not do their own work, they may be assured it will be left undone. From the late day of the meeting, and the crowded state of our columns, we must content ourselves this week with a recommendation to the perusal of the proceedings, and an earnest injunction to a general co-operation with them.

Iterum Iterum Iterumque.

OUR readers will recollect that, some months back, (April 11th,) we recorded, with comment the case of Geach versus Ingall,—an action brought for the recovery of a policy of insurance amounting to 2000*l*. For the third time, the case was tried at Warwick on Friday and Saturday last. The payment of the policy was resisted, on the ground that the individual was not in a sound state of health at the time the insurance was effected. He applied for admission into the Norwich Union Office and was declared by the late Dr. Ingleby of Birmingham a fit subject for assurance. He was afterwards advised to enter the Imperial, and was admitted into it after a careful examination by Mr. Wickenden, a surgeon of unexceptionable skill and character in Birmingham. Scott, the insured, died in 1843 of consumption, of which, in its incipiency, the company believed him to have been the subject, at the time of his admission. Hence the litigation. The evidence on both sides was of a very positive nature; though sundry of the witnesses for the defendant were somewhat straggling in their relative testimony. The question, altogether, turned upon spitting of blood, and its probable concomitants. The man was inquired of, as usual, at his examination, whether he had ever had spitting of blood, or other symptoms of disease in the lungs, and his answer was in the negative. Several of the witnesses, however, swore that he had spat blood both prior and subsequently to his admission. Of these witnesses his wife and various relatives were the chief. Certainly they, of all other people, ought best to know what common ailments the deceased suffered from; and doubtless their evidence would have carried considerable weight with it, but that there was every reason to believe it to be intentionally one sided. Scott failed, some time before his death, and his policy was bought by a party against whom the witnesses entertained no feelings the reverse of friendly. They were consequently not over particular either in making statements or sticking to them. After their examination, several eminent medical men, amongst whom were Dr. Tweedie and Mr. Lawrence, testified to the probability of the deceased having had tuberculous disease of his lungs at the time his insurance was effected. The witnesses for the plaintiff testified as strongly in an opposite strain. Many who had known him intimately for years, had worked with him, and slept with him, declared that they had never known him to spit blood, and that in all respects he was a "strong, wiry man." It seems that he could endure great fatigue without suffering from it, and had frequently sustained with impunity, considerable vicissitude and exposure.

The statements having been fully heard on both sides, the jury, with little deliberation, returned for the third time, a verdict for the plaintiff to the full amount of the policy.

We quote this case, because of its medico-legal interest, and of the uses it may possibly serve as a precedent in future similar litigations.

Without for a moment wishing to reflect upon the Imperial Office, we cannot help thinking that in the present case, they were guilty, to say the least of it, of indiscretion. The insured had been passed by the medical referee of the Norwich Union, before applying for admission into the Imperial, the medical officer of which, again, gave him an unqualified certificate of soundness. In a few years afterwards, the man dies after a not protracted illness, and an idle rumour arising in a family feud, about the deceased having spat blood, this is forthwith seized upon as a plea for the non-payment of the policy. And not satisfied with one verdict, it is brought before a jury three several times, at a cost which we apprehend will leave little of the 2000*l*. as a memento of victory.

As we have said, the whole question, or rather

quibble, turned upon the spitting of blood, and the probability of its connexion with diseased lungs. There was no direct evidence whatever, that the medical examiners could detect, or that the man's friends and fellow workmen had ever observed, of his tendency to pulmonary consumption. All that could be said of one party, not very distinguished for general good character or veracity, was, that the man had been known to spit blood,—not frequently, and never in profusion, but now and then, mixed with mucus, when he was suffering from ulcerated sore throat. Another party, that had for years been in almost daily communication with the man, swore that they had never observed any such thing. Certainly, with conflicting evidence like this, backed by the certificates of two competent medical men, it seems anything but an act of wisdom to send the case three times before a jury. But granting that the man had been seen to spit blood, this is no proof that his lungs were diseased. We apprehend that very few people pass through life without spitting blood some time or other. Very many people, in certain states of dyspepsia, or disordered general health, are as subject to bleeding from the gums, the mucous membrane of the mouth, the fauces, or the tonsils, as others, suffering from determination of blood to the head, are liable to bleeding from the nose. And if an ignorant bystander, seeing a man spit blood under the circumstances above mentioned, or after having picked his teeth, or chafed his gums, is to report the poor fellow the victim of hæmoptysis, and on this solitary ground an exception is to be taken to his health, and to the validity of his assurance, we expect very few to be safe. Any man, at this rate, might be made the subject of disqualification. In strictest language, the ejection of blood from the mouth is *spitting* of blood, no matter what the source of it; but this is not the conventional signification of the phrase, nor that to which it is strictly limited as the question of an insurance office. The expression bears relation to the origin of the effusion, not to its exit from the mouth. Spitting of blood, whether the term be popular or professional, is always understood to signify *hæmoptysis*—the expectoration of blood. This is precisely the sense in which it is applied in insurance questioning, for it is generally followed by—"or other disease of the lungs." Hæmoptysis is always regarded as very probable evidence of pulmonary disease, if it be not a vicarious function; and the inquiring concerning it, like other inquiries respecting coughs, expectoration, pains in the chest, &c., is not put on account of itself, (the hæmoptysis), but on account of the ailment of which it is likely to be a symptom. But to say that the mere fact of a man having spat blood is proof of his physical unsoundness, it being unknown from what quarter the blood proceeded, or what was the cause of its discharge, is about as rational as to charge a man with chest affection because he was known to have a violent cough, consequent upon having half choked himself with some beverage or other swallowed too hastily.

Yet an injustice of this sort has been perpetrated, and we fear often. Ourselves once knew a man refused admittance into an insurance office, despite the testimony of his own surgeon, and of the physician to the institution in his favour, merely because one of the clerks of the company deposed to having more than once seen the poor fellow spit blood. The fact was, they were in the habit of smoking a pipe together, occasionally, at the same tavern, and it was the custom of the individual in question to pick his teeth after having finished his tobacco, and that little dental operation was generally followed by loss of blood from the gums. The case of the sufferer was hard enough; for not only was he refused admittance into the office in question, but the other offices in the town, hearing of his rejection by the one aforesaid, refused him also, and he was therefore left utterly without the means of making the provision he desired for his wife and children. He was in truth a living illustration of the old proverb which speaks of giving "a dog a bad name." But bad as his case was, it would have been much worse had his idle story got afloat some time after his admission into an insurance office, and the company warned him to retire on pain of expulsion for having intentionally attempted to defraud them; or if, having been duly and honourably admitted, he had paid through a long course of instalment, and at last died, in obedience to the common law from which none are exempt, and the company having found out from some idle tale-teller the unworthy quibble in question, the widow and orphan children of this poor fellow had been deprived of their rights, and made paupers through the instrumentality of a little pot-house or street gossip. Such would inevitably have been the issue, had the man been placed in the circumstances above mentioned.

As we before said, we make no comments on the case upon which we base this article; but we cannot help thinking with the judge, and the jury, that two opinions could scarcely be formed upon it, and we sincerely hope, for the credit of medical jurisprudence, that we shall seldom have such litigation re-enacted.

A case like this, however, is one from which some useful hints may be derived. It would, perhaps, have saved the plaintiffs some trouble, had Scott, when questioned as to spitting of blood, have answered the query negatively, as regarded *coughing it up*, and positively, in reference to casually discharging it from his gums, palate, &c. We would, therefore, gladly take the present opportunity of advising all whom it may concern, to weigh well their words in the process of passing an insurance examination, and to let their answers be "the truth, the whole truth, and nothing but the truth." These valuable items provided, and being afterwards produced, will be the surest safeguards against private hostility or party injustice. It is better, also, that a man should have the testimony of his family surgeon, in addition to that of the medical officer of the company. This private testimony, duly authenticated and witnessed, he should keep by him as he keeps his will, to be used after his death in case its proof be necessary. We earnestly hope that the advice we now give will be followed by those to whom it relates. The trouble or inconvenience attending it, will be but little, and as we have just seen, it may save a multitude of annoyances and costs.

Medical referees, again, should learn from an example like this, the desirableness of exercising the severest scrutiny in their practical duties. Nothing that manipulations, observation, or questioning, can elicit, should be disregarded by them. They have a serious duty to perform to two parties, and they should discharge it scrupulously. Their great, nay, their only duty, is DIAGNOSIS; let them answer this *scientifically*, and neither themselves nor others need be apprehensive of the results. If the questioning be pathologically rigid, and the answers honestly exact, insured parties may feel perfectly satisfied as to the security of their policies.

FORMATION OF THE NATIONAL INSTITUTE OF PRACTITIONERS IN MEDICINE, SURGERY, AND MIDWIFERY.

A well attended and highly influential meeting of general practitioners was held at the Hanover-square-rooms, on Wednesday evening last, to receive a report from the committee of the National Association, and to decide on the propriety of immediately forming a NATIONAL INSTITUTE OF GENERAL PRACTITIONERS IN MEDICINE, SURGERY AND MIDWIFERY. Numerous gentlemen from the country attended and the meeting included most of the influential medical men in general practice in London and its environs.

The venerable president R. R Pennington, esq. having been unanimously elected to the chair, rose and was received with much cheering: he said.—

Gentlemen, I am so anxious to testify, by every act in my power, to the general Practitioners of this country, and to the members of the National Association in particular, how deeply interested I am in all that concerns them, that I have cheerfully consented to take the chair on the present occasion.

There is scarcely any personal sacrifice, that I would not readily have made rather than forego the pleasure of being here this evening, to participate in the proceedings of this meeting. I wish to stimulate, by the force and spirit of my example, as many as I can of my professional brethren to shake off their apathy, and to induce them to take an interest in what is going on in matters relating to the medical profession. I wish them also just to enquire into the principles of the association over which I have the honour to preside; and, if they will only take the trouble carefully and dispassionately to consider what it is we are contending for, I should not then at all despair of seeing all the intelligent and influential members of the profession, from one end of the kingdom to the other, come and enroll themselves as members of our body. Gentlemen, we are contending for the principle that medicine and surgery are educationally one and the same science, and that nine-tenths of the medical profession in this country are practising, and must continue to practise, on this principle. We contend that special institutions, for sectional departments of medical science, however valuable, can never supersede the necessity of an institution comprising, within itself, the entire range of medical and surgical knowledge.

We assert that a knowledge of pharmacy is an essential element in medical education, and that the large amount of responsibility involved in the practice of pharmacy renders it desirable that it should continue in the hands of medical practitioners. Society has decided that it should be so and medical men have no right to insist that it should be otherwise. We in no way admit that the practice of pharmacy should imply professional inferiority or that it is incompatible with a high standard of general and scientific knowledge. The National Association was formed to protect the interest of the Public and of the Profession: to secure to the former an enlightened and intelligent body, to administer to the maladies of all classes alike, and to attain for the latter that rank and position their extended sphere of usefulness so fully entitles them to occupy.

Gentlemen, it is to perpetuate the National Association, to carry out more effectually the objects for which it was formed by giving it a more permanent character, that we have assembled here this evening. It will be proposed to you in the report from the committee appointed to ascertain the sentiments of the profession on the subject, to declare the formation of a NATIONAL INSTITUTE OF MEDICINE, SURGERY, and MIDWIFERY.

I doubt not your ready acquiescence in the recommendation of your committee.

For my own part the plan has my entire and perfect concurrence, and I look forward with confident hope that through its means and the able and judicious conduct of those gentlemen to whom will be deputed the management of the Institution, we shall finally succeed in our objects.

REPORT.

A General Meeting of the National Association was held on the 17th day of April 1846, when it was unanimously resolved, that in consequence of the indefinite postponement of the settlement of the Medical question in parliament, an absolute necessity existed for the general practitioners of the kingdom to maintain a permanent collective organization; and that the National Association of General Practitioners in Medicine, Surgery, and Midwifery, should be established on a more permanent basis. The Meeting also resolved, that the members of the association and other members of the profession should be canvassed as to their willingness to co-operate in the formation of a "National Institute of Medicine Surgery, and Midwifery" upon the plan which had been fully discussed and agreed upon by the association.

The committee were requested to continue their functions for the purpose of carrying out these resolutions, and of again calling a General Meeting to report to the association and to other members of the profession on the formation of such a National Institute.

Your Committee proceeded, with as little delay as possible, to forward to each member of the Association a schedule containing the necessary inquiries, of which a copy is subjoined, accompanied by a circular letter dated the 27th of May, 1846, setting forth the plan and objects of the proposed institute.

One thousand, three hundred and thirty-seven of these schedules have been returned; and out of this number one thousand two hundred and eighty-eight gentlemen have expressed their willingness to co operate in the formation of the National Institute upon the principles and for the objects detailed in the circular letters alluded to.

The letter was framed from the report adopted by the members of the Association at the meeting of the 17th of April, and the committee take this opportunity of reminding the members that the objects of the proposed National Institute are in strict accordance with those which first called the National Association into existence, as follows:—

I To form a complete organization of the general practitioners of medicine, surgery, and midwifery, in a representative institution, on a permanent basis, with an authoritative council for the purpose of watching the course of medical affairs,—of advising the members of the nature and bearings of any legislative changes that may be proposed,—of taking such steps thereon as the circumstances of the profession may demand, and generally of protecting the interests of the qualified practitioners and of the public in all matters that relate to medical legislation.

II. To adopt a comprehensive and well considered code of bye-laws, for the government of the institution, calculated to produce harmony of sentiment and unity of action among the members; to discourage, as far as practicable, discreditable acts in connexion with the practice of medicine, and thereby to promote the true respectability of the great body of the profession

III. To promote a high standard of education and qualification, with a satisfactory test by efficient examinations, for every individual authorised, by law, to practice medicine, surgery, and midwifery. In furtherance of this object, to encourage the Apothecaries' Society to prosecute their duties with increased zeal, and to continue to elevate the character of their examinations also to watch, from time to time, the standard of qualification for the membership of the College of Surgeons, and, if found to be insufficient, to adopt such measures as may be best calculated to promote the efficiency of the member to practise surgery as a general practitioner.

IV. To use every practicable and legitimate means to expose, discourage, and suppress illegal and unqualified practice. In the absence of any legal registration, to publish, or to further the publication on authority, of a complete register of the qualified practitioners in actual practice, hereby giving facilities to the Society of Apothecaries for prosecuting those who may render themselves amenable to the law

V To carry out as far as the funds placed at its disposal may permit, those professional and social objects which have been found so advantageous to other collective bodies of educated men, among which may be enumerated;—the formation of a library,—the collection of a museum,—the occasional publication of transactions,—the opening of reading and lecture rooms and of a common hall,—and the establishment of prize essays and public examinations on specific subjects. By such means to enlist the zeal and ability of the great body of the profession in the cause of medical and general science to perpetuate their labours and experience, and to facilitate direct and friendly communication between the central council, the local secretaries, and the members of branch associations.

VI To employ all legitimate means for the purpose of urging upon the Government and the Legislature the claims of the general practitioners of this country to corporate rights, and to an Act of Parliament securing to the public a high standard of qualification and competency for every individual allowed by law to practise medicine, with protection against unqualified pretenders; and to the profession at large, those rights and privileges for which they have so long contended.

VII. To constitute a body competent to negotiate with the Government in the event of the Right Hon. the Secretary of State for the Home Department redeeming his original pledge to grant the general practitioners a charter of incorporation.

The 1288 gentlemen who have agreed to take the initiative in the formation of the National Institute, have furnished the committee with their names, addresses, and professional qualifications, and they have intimated their willingness to become members, and to join in such annual contributions, as may be necessary for the maintenance of the Institute.

The correspondence, in which your committee have been engaged on the subject of the formation of an Institute, has made them acquainted with several causes, which have induced some of the members of the association to withhold for the present, the return of their schedules.—Many have done so in consequence of the uncertainty, which exists, as to the amount of the annual contribution; others have expressed a desire for various reasons to await the actual formation of the Institute, and a few have declined the responsibility, until they are assured that what they themselves consider to be a sufficient number of individuals shall have joined it. From the circumstance, that a large majority of the returns which have come to hand, are from gentlemen possessed of a double qualification, and from other information, your committee have also reason to believe that some members of the profession having a single qualification, withhold their names, owing to a misapprehension of the intentions of the association. It will be seen by reference to the plan, the intention is, that the Institute should embrace all who are in actual practice as general practitioners, whether possessed of one or more qualifications from any of the existing colleges; and who are favourable to the founding of a new institute, upon the broad principle, that medicine and surgery are one science; and provided they join the Institute within six months from the date of its formation. After that period the qualification for the membership of the Institute will rest with the council, and the laws and ordinances hereafter to be enacted, which must be in strict accordance with the fundamental principle of the Institute, viz: That every general practitioner shall give evidence of his education and qualification to practise medicine, surgery and midwifery.

Although a large number of members of the association have not at present made a return, several highly respectable members of the profession, not being members of the Association have applied for schedules, and have returned them with an intimation of their desire to become members of the National Institute. Under these circumstances, your committee have deemed it expedient to call this meeting without further delay, for the purpose of declaring the formation of the "National Institute of Medicine Surgery and Midwifery." The committee regard the prospect of the new institution, as respects its numerical strength as most encouraging. They have no reason to doubt that the bulk of the members of the National Association will ultimately belong to the Institute, and they have reason to believe that the great body of general practitioners of this country, will eventually enlist themselves in its ranks.

A large majority of the returns are in favour of there being no distinction between the metropolitan and provincial members, as respects the annual payment for the support of the Institute, and a similar majority is in favour of that payment being fixed at one guinea. As it appears to be important that this question should be settled as far as may be practicable, the committee recommend that the annual contribution should be fixed at this amount.

Your committee in their former reports, have entered so fully into the business of the Association, and the various details of medical affairs, that they do not now deem it necessary to detain the meeting with any lengthened statement.

As respects the income of the National Institute, it is obvious that 1288 guineas per annum, would not be adequate to carry out the whole of its objects, it will accordingly be the duty of the first council, to regulate their proceedings with a strict regard to economy; to limit the operations of the Institute according to its funds, and to pursue those objects in the first instance, which are most essential to the interests of the general practitioners, and especially to the obtaining to their corporate and political rights. In proportion to the number of members, and the amount of the annual income the remaining highly desirable objects may be attained.

Since the last meeting of the association a great political change has taken place, and your

committee are willing to regard it as favourable to the interests of the medical profession, and more especially to those of the great body of general practitioners. A ministry standing avowedly on the principle of social improvement, through the education of the mass of the population, cannot for one moment desire to evade the question of medical reform, however difficult and complicated. It is apparent that a high standard of education, and qualification for every individual undertaking the responsible duties of a medical practitioner, ought to constitute the main feature of that reform.

It will obviously be one of the earliest duties of the council of the National Institute, to place themselves in communication with the Government, and as an organized body, representing the interests of the great mass of medical practitioners throughout the kingdom, to avail themselves of their position, for the purpose of accomplishing, by every legitimate means, such alterations in the scheme of medical politics, as may protect the public from unqualified practitioners promote the welfare and security of the community at large, and sustain the honour and respectability of the profession.

(Signed)
JOHN NUSSEY, Chairman.

COPY OF THE SCHEDULE.

GENTLEMEN,

I beg to forward my replies to the following Questions:

1. Are you willing to co-operate in the formation of a National Institute of Medicine, Surgery and Midwifery, upon the plan detailed in the accompanying letter, by becoming a member, and contributing towards its support?

2. That the committee may be enabled to estimate the sum at which the annual contribution for the support of the Institute should be fixed, what is your opinion as to the amount of such payment by the metropolitan and provincial members respectively?

For Metropolitan Members
£ s d

For Provincial Members
£

UNLIMITED?

3. At what period after the date of his qualification to practise should a member of the new Institute be eligible for a seat in the council?

10

I am,
GENTLEMEN,
Your obedient Servant,
Name
Residence
Qualification

To the Committee of the National Association of General Practitioners in Medicine, Surgery and Midwifery,
294, REGENT STREET.

Mr. Martin of Reigate then rose and said that he felt himself highly honoured by being entrusted with the resolution he held in his hand viz, "that the report just read be received." He could conceive no matter of greater importance to the profession generally, as well as to the public at large than the formation of the National Institute which had been proposed to the meeting. He could not doubt of the unanimous reception of the report, therefore he should not take up the time of the meeting by any observations respecting it.

Mr. Burnett of Alton had much pleasure in seconding the resolution, which was then put from the chair and carried unanimously.

Mr Clifton of Islington had felt peculiar pleasure in receiving the resolution entrusted to him to be submitted to the meeting. He believed that the step now to be taken would be well fitted to form the basis of a new state of things in the medical profession. It had long been the reproach of the general practitioners that they had not kept the public position due to them. He must attribute this to their confining themselves to the support of science and the advancement of the scientific part of medical practice without meddling in public matters. Gentlemen belonging to the medical profession had not remembered the old and true adage that 'union makes strength.' For his own part he believed that the formation of the Institute would be the foundation of an institution that neither statesmen nor others would be able to treat with contempt. He believed that for the future a new light would dawn on the profession and that it would assume its proper status in society. He believed too that the advantages from the formation of the National Institute would be such as to benefit the community at large. General practitioners had hitherto had much to complain of, they had been repudiated by the college of physicians and insulted by the college of surgeons, but they would be found to constitute a body able to maintain their position among the scientific men of all countries. As a proof of this he would instance the periodical medical literature of the day, supported almost solely by general practitioners, and then ask if the general practitioners were not able to maintain their position. He looked forward with much hope to the council which was to be elected, and to the standing which they would occupy in the medical world, both individually and collectively. This council would be able to come forward with their claims on the government and they would not be repulsed. They would form an organ by means of which the wrongs of the general practitioners would be redressed. He felt that the practitioners to whom the health of the country was entrusted, were entitled to all they had asked, and he had every reason to believe that the ends they sought, were calculated to promote the interests of society, by placing the value of scientific medical practice more prominently before the public, and discouraging charlatanism. Great is the truth, and it must ultimately prevail. One thing, however, he wished to impress upon the meeting; it was that not by all they should obtain, nor by all they could demand, would they elevate the profession permanently in the esteem of the worthy, without raising the standard of medical knowledge, and encouraging honourable conduct among themselves. He would no longer detain the meeting, except to read the resolution, which he had no doubt would be received unanimously.

Resolution 2.—That this meeting hereby declares the formation of a "NATIONAL INSTITUTE OF MEDICINE, SURGERY AND MIDWIFERY" upon the plan approved by the meeting of the national Association held at the Hanover Square Rooms on the 17th of April 1846, and with the objects recited in the Report just read. That the Institute consist of those gentlemen who have already signified their intention to co-operate in the formation of the same, with such other qualified practitioners as may join within the specified time, or who may become members in accordance with the future arrangements of a regularly constituted Council.

Mr. Fuller of Piccadilly, said that what Mr. Clifton had just told them had been said so much the purpose that he should not trouble them with a single remark except to impress on them the importance of the act they were about to perform. They were about to establish an institution that would overshadow the land and the benefits of which would be felt by all in the kingdom. He was old enough to remember the state of the profession before the passing of the Apothecaries, act of 1815, and he could recollect the position held by medical practitioners, before that period. General practitioners had proved to the world that they were an educated body of gentlemen who were both physicians and surgeons, and as such able to practise all branches of the profession. The late secretary of state asked what position the general practitioners held, the formation of this institution would prevent such a question from being necessary for the future. Mr Fuller would conclude by heartily seconding the resolution before the meeting.

The resolution was then put from the chair and carried unanimously with much applause.

Mr Propert had much pleasure in coming forward to propose the resolution he held in his hand. The meeting had heard so much of the advantage to be expected of the association from Mr Clifton that he had only to say he believed that the profession in future times would look back on this association with feelings of pleasure and gratitude. The resolution he held was one of the most important of the night,—it was respecting the sinews of war. The question of the amount of annual contribution had been put to all the members of the Association and the answers had been unanimously in favour of an annual contribution of one guinea each member with no difference between country and town members. He would read the resolution he had to propose to the meeting.

Resolution 3.—That in accordance with the recommendation of the Committee, it is the opinion of this meeting that the annual contribution for the membership of the National Institute should be fixed at one guinea.

He wished however to correct an erroneous impression which might get abroad; the profession must be aware that heavy expenses would attend the formation of the institute, and although the annual subscription was fixed at one guinea, all contributions from the more wealthy members of the profession would be received most thankfully. They had a large institution to form, and a museum and library to collect and consequently their expenses must be heavy.

Mr. Septimus Reid had much pleasure in seconding the resolution, which was then put from the chair, and carried unanimously.

Mr. Smith felt great pleasure in proposing the fourth resolution which he would read to the meeting.

Resolution 4.—That those Members of the Provisional Committee who have expressed their willingness to join the National Institute, be requested to proceed with the Enrolment, and to call a meeting of the Members of the National Institute, at as early a period as possible, that the necessary steps may be taken for the election of the Council and the officers.

It was an important feature in the institute that the direction and government would be alone vested in the body of which it was formed. For what reason had they formed that association? Mainly because the general practitioners of the whole country, and of the whole world, the men who were called in in all parts of the world had been grossly insulted by the college of surgeons. He had some difficulty at first in persuading himself to join the association because he had felt unwilling to leave the college of surgeons, but the council of the college had themselves severed the bond. Was it not monstrous that the members of a body who had been certified to be surgeons should be told by the very parties certifying that they were only fit for the ordinary exigencies of surgery? Who the pure surgeons? They did not exist, or if there were one he ought to be turned out of the profession. Many of the men who had been still looked up to as the heads of the profession were imbued with general science. He, Mr. Smith, knew a surgeon, a hospital surgeon, and one for whom he entertained the greatest respect, whom he once saw write a prescription; he afterwards told that surgeon that there was a decomposition in his prescription. It had been the fashion to vilify the apothecaries company, and in connexion with this he would mention a fact, Dr. Elliotson, a man, perhaps, led away by peculiar views, but still a man imbued with general science, had asked him, Mr. Smith, when in 1827 he presented himself for examination before the apothecaries company, to give him an account of his examination. He had done so, and Dr. Elliotson had then said, "if these are your examinations, the college of physicians must advance the standard of their education, or you will tread on their heels." The general practitioners had submitted to what a large number of the fellows of the college of surgeons had never submitted, and this was the reason that made him (Mr. Smith) first join the association. If unable to prevail with the executive government, it still remained for the association to advance the standard of their education, till they not only trod on the heels of the colleges, but actually tripped them up.

Mr. Harper fully concurred in the remarks of Mr. Smith. He had much pleasure in seconding the resolution. The resolution was then put from the chair, and carried unanimously.

Dr. Webster was happy in being able to do anything for the advancement of his profession. He had not been present in the last two or three meetings of the association, but he was rejoiced to find the resolution he was about to read put into his hands.

Resolution 5.—That henceforward, the interests of the National Association of General Practitioners be intrusted to the Council of the National Institute of Medicine, Surgery, and Midwifery—their principles and objects being identical.

He was unwilling that the association which had been founded for important purposes should die, and he felt much satisfaction in being present at its crowning work. It had been said that there was no necessity for a third body in the profession; but a third body was wanted, because the physicians and surgeons were special bodies, who were not qualified to act generally. Dr. Webster hoped that the days were now past when the surgeon, with Sir Astley Cooper, could "thank God that he knew nothing of physic." He would like to see the man who could, with any truth say he was a pure surgeon; he would place him in their Museum, and keep him as a natural curiosity. He would be sorry to see the day when pharmacy would be separated from the practice of the general practitioners, for his part he would be sorry to trust his prescriptions to the druggists of the present day. In Scotland practitioners all dispensed their own medicine, even the highest, as Gregory, Abercrombie, Russell &c. Dr. Webster looked on his country brethren as the true general practitioners. Medicine and Surgery could only be considered as one Science and indivisible and Dr. Webster thought perhaps that the general practitioners of the metropolis did not cultivate sufficiently the use of the knife. Dr. Webster needed not to say that he should give the formation of the institute his most cordial support.

Mr. Wallace in seconding the resolution wished to make a few remarks on one portion of the scheme; he alluded to the election of the council governing the new institute this was to be elected on the representative principle. The complete organisation of the medical profession was a great step, and one that could only be rendered permanently secure by the establishment of the representative principle.

The resolution was put from the chair, and carried unanimously.

Mr. Clifton wished to advert to the fact that the National Association had now been in operation two years. He had had an opportunity of observing all the proceedings of the body, and the result of his experience was the highest estimation of the characters and attainments of the gentlemen he was about to name. He felt the most lively pleasure in proposing a very small instalment of a very heavy debt of gratitude to their honoured secretaries, Messrs. Bird and Ancell. He felt that any encomium of his own on these gentlemen would but ill express the feeling of the profession towards them.

The association had never had occasion once to retrace its steps during the long period of its existence, and that was saying a great deal of a very large public body of gentlemen unaccustomed to business, and he felt that it was entirely due to the tact of the two gentlemen who had managed the affairs of the association. It rarely occurred that two gentlemen associated in such a work worked together so well. He might well say that what the one wanted, the other supplied. He had the most lively pleasure in proposing the resolution he was about to read to the meeting.

Resolution 6.—That the particular and grateful thanks of this meeting, be presented to the honorary secretaries, Messrs Bird and Ancell for their unparallelled and devoted exertions in the cause of medical Reform; for the zeal and ability with which they have discharged the arduous and important duties devolving upon them and for the kindness and urbanity they have uniformly evinced, in their Communications with the members of this Association.

He would only add that he hoped the resolution would be carried by acclamation.

Mr. Headland had much pleasure in seconding the resolution. He had had abundant opportunity of observing the great judgment and tact of the gentlemen who had given their service as honorary secretaries. Indeed he felt it would have been impossible to have found two gentlemen who would have conducted the affairs of the Association with equal zeal, prudence and skill.

A gentleman in the body of the room, whose name we did not catch, but who stated that he was not a member of the committee, wished to say a few words in support of the resolution. He said it became every one, when an opportunity offered, to express his gratitude to the gentlemen who had given up their invaluable time to the affairs of the association. He believed it impossible for any gentleman who had not taken a prominent position in the movement to appreciate the value of their services or to be aware of the skill with which they had smoothed all differences of opinion in a Committee comprising one hundred members, and the urbanity and kindness they had displayed on all occasions. The resolution was carried by acclamation.

Mr. Bird felt totally unable to express his gratitude for the encomiums which had been bestowed on the services of both himself and Mr. Ancell. That there had been great demands both on their time and attention, it would be affectation in him to deny; but when he saw some gentlemen, such as their venerable president, leave the retirement of private life and come into the turmoil and agitation of a public controversy for the benefit of the profession of which he was at once the ornament and the friend, men with hearts like his own, could not stand by and idly refuse to co-operate. There were two periods in a medical man's life when he might justly avail himself of any honourable means for attaining a prominent position in the estimation of his professional brethren—the one in the outset of life, with the buoyancy of youth and a praiseworthy ambition to assist him in his onward career, and the other at the period of his decline, when a lengthened experience could be advantageously devoted to the service of his professional brethren. Neither of those periods applied to him; notoriety he did not desire; his position in the profession was already formed, that position he had long continued to hold, and to the unostentatious performance of his professional duties he wished, when the association should no longer need his services, quietly to return. He wished before he sat down to express his feeling of the mode of which he had been assisted by his colleague Mr. Ancell. The untiring zeal, great ability, and perfect disinterestedness of his respected colleagues' labours fully entitled him to those marks of approbation so liberally bestowed upon him by the meeting. He wished also to say a few words respecting the gentlemen of the committee with whom he had been associated, gentlemen brought together from all parts of the metropolis, and from all parts of the country without the slightest previous concert or knowledge of each other; and if their gentlemanly bearing, their able and judicious management, and their temperate and dignified conduct throughout all their proceedings, might be looked upon as a type of the council of the proposed Institute: then indeed he could safely predict that the new institution would, under the direction of such a council, speedily reign paramount.

Mr Bird concluded a very affecting address amidst much feeling.

Mr. Ancell in returning thanks, stated that he had not willingly entered the arena of medical politics. Until the last two years, he had never taken an active part in any political matters, medical or otherwise, and it was a subject of some regret, that those who first induced him to act in public, when he differed in opinion from them, or rather when those with whom he acted differed in opinion, they were the first to turn and abuse him. The agitation and turmoil of politics, was quite inimical to his usual habits and pursuits. Those who knew him, were well aware, that in the absence of the best opportunities, he had still used his endeavours to contribute his mite towards the advancement of the science of the profession, the interest of which he had at heart. It would be affectation to say, that the interruption by recent events in those pursuits and objects, which he had made the business of his life had not been an inconvenience to him; but he begged to tender to the gentlemen who had brought forward the resolution, and to the meeting his grateful thanks for the handsome manner in which his services had been acknowledged. He considered the approbation of his conduct, thus expressed by his professional brethren, an ample reward for any trouble or inconvenience to which he had been put. In common with other members of the college of surgeons, he certainly did feel aggrieved when he found the door of that college, which the members might call their own, virtually shut against them; although personally he was very indifferent about it, for he was certain that a professional reputation did not depend upon the distentions, arbitrarily drawn, by the council of the College of Surgeons. Members of the college of his own standing, and his juniors had reasons to be grateful to their venerable president, and to let the senior members of the profession, who had so handsomely come forward with their time, their influence, and their purses; they could have no personal interest, whatever in any changes that may be effected in the profession, and they have stood forward in the most handsome manner, for the benefit of their professional brethren. He was happy to hear Mr. Webster speak out on the subject of the medical practitioners, dispensing his medicines; and he might be permitted to remark further, that we are engaged in a war of opi-

sions. At all events the colleges employ their influence in high quarters, to induce the belief that they are opposed to the practitioner dispensing his medicines, and to what has been called a third estate in the profession. But the fact is not so, they are not opposed to a third class, but they are opposed to the present educated class of general practitioners. They wish for a third class' but they desire the pharmaceutical society to take the place of the present class of general practitioner. He recommended his professional brethren not to relinquish the dispensing of medicine, at all events in the present state of the law. He might enter at large upon the topics of medical reform, but they had so often been discussed in public, and in committees and sub-committees, and also with deputations from different sections of the associations, and these discussions had always terminated in such perfect uniformity of sentiment and action that it would be only a trespass on the time of the association to do so, and he would conclude by again returning his grateful thanks to the meeting for their resolution.

Mr. Cooper then said, that there was one subject to which he wished to call the attention of the meeting—he meant the bill, now before parliament for the registration of the profession. He was cognizant of the fact that the colleges of physicians and surgeons had bestirred themselves against this bill, which they considered an infringement of their rights. He would therefore propose that a sub-committee should be formed to watch the progress of the bill, and to guard the interests of the general practitioners. He believed that the bill was intended merely to provide for the formation of an alphabetical list of the gentlemen in actual practice throughout the Kingdom. It had been suggested, that the bill would not go through the house. He could not agree in that opinion. He did not believe the bill had been shelved, but if, as it had been suggested, it were really dropped, the committee would of course be dissolved. If on the other hand, the bill were really carried on, the committee would watch the interest of the general practitioners.

Mr. Clifton thought there could not be two opinions respecting the advantages of a complete registration of the profession, but at the same time he must declare that he thought some of the provisions of the bill were dangerous. The committee had, immediately they got the bill into their hands, taken its clauses into consideration, and had immediately transmitted resolutions respecting it to influential quarters. It had therefore already been fully discussed by the committee.

Mr. Cooper had heard nothing from Mr. Clifton to convince him that the bill should not be then discussed.

A gentleman whose name we did not hear, said that he must request Mr. Cooper to withdraw his resolution; he was unwilling, unnecessarily to hamper the committee by the appointment of additional sub-committees.

Mr. Woolridge of Southampton, had only received the bill yesterday morning, but it appeared to him, that one of its provisions would prevent a member of the Apothecaries company only from ranking as a surgeon, he must say he objected to this as he thought it would tend to disturb still more the already divided state of the profession.

Mr. Clifton would, if the chairman thought this a proposition which could be discussed by the meeting, immediately read the resolution passed by the committee after considering the bill.

Mr. Smith thought that this question was simply one of confidence in the committee; the committee had already considered the bill, and made a representation respecting it in proper quarter. He considered that this was a question, which could not be discussed by that meeting which had been called for a special purpose.

Mr. Cooper should leave the matter in the hands of the chairman.

The question was put to the chairman, who decided that the meeting having been called for a special purpose, a discussion on the bill would be out of order.

A vote of thanks to the chairman was then proposed, seconded, and carried by acclamation, and the meeting separated. The greatest unanimity prevailed throughout the whole proceedings.

Miscellaneous Correspondence.

THE HOUNSLOW FLOGGING CASE BY JOHN HALL M.D., STAFF SURGEON FIRST CLASS.

To the Editor of the Medical Times.

Sir,—Much misconception appears to exist regarding the case of the unfortunate man Frederick John White, which has lately been investigated by a Coroner's Inquest at Hounslow; and as the Coroner has throughout the investigation endeavoured to throw discredit on the medical men connected with the army, perhaps, you will afford space for the accompanying statement which I drew up with a view of refuting Mr. Wilson's novel doctrines, and of explaining the reasons why I thought White's fatal disease was more likely to have been occasioned by exposure to atmospheric changes after exertion, than by the flogging which he received on the 15th of June, and from which he had recovered.

Mr. Wakley interrupted the reading of the paper by other matter, as I expected; and I cannot say that I regret the interruption so far as the Jury were concerned.

I am, Sir,
Your most obedient Servant,
John Hall.

Thursday morning 6th of August 1846.

REPORT DRAWN UP TO BE READ AT THE INQUEST, BUT INTERRUPTED BY THE CORONER.

After a careful consideration of all that I have heard stated concerning the case of White, I am still of opinion that inflammation of the heart, lungs, and pleura was the immediate cause of his death, and I cannot, with satisfaction to my own mind, connect it with the punishment which he underwent on the 15th of June; nor can I subscribe to the novel doctrine which has been advanced by Mr. Wilson for that purpose; and if you will permit it, I will briefly state why.

Mr Wilson states, that, on cutting down on the opposite side of the spine to that on which the integuments had been removed at the first post mortem examination, he discovered pulpy softening of the deep seated muscles to the extent of three inches in length, and one inch in breadth, but the superficial muscles over the part were all free from injury or change. He does not ascribe this changed condition of the deep seated muscles to the direct violence of the lash, as they were protected from that, by their position, and by the super-jacent parts, but to excessive contraction during the agony of punishment, and subsequent disorganizing inflammation from nervous depression.

Now White was in the prime of life, and does not appear, by the statements we have just heard read, to have suffered much from nervous depression. It is strange, therefore, and unaccountable to me, why nature should have made no effort to repair this injury, or that her efforts should have been of a disorganizing kind in this particular spot, while the process of healthy reparation was proceeding rapidly in other parts of his frame. The injury itself, too, is one of a novel kind, and difficult to reconcile to our pre-conceived opinions of the power and action of the small muscles alluded to. White, the witnesses all say, bore his punishment without any struggling, and Dr. Warren says he observed no spasmodic action of the muscles of the spine. Besides, had Mr. Wilson ever witnessed the infliction of corporal punishment he would have seen that it is the superficial layers of muscles, which attach the shoulder blades to the spine, that are thrown into action, and had any rupture of muscular fibre taken place from violent contraction, it would most likely have occurred amongst these, and not among the deeper seated on a along the spine, which have such limited contractile power, and are so well protected from injury.

Mr. Wilson lays much stress on the injurious effects likely to have been produced by this altered portion of muscle lying in contact with the intercostal spaces, but it seems to have escaped his recollection, that the cavity of the chest on that side was filled with diseased and disorganized viscera, and highly putrid fluids which were much more likely to have contaminated the adjacent muscles than that the small portion of pulpy fibred, should have occasioned the extensive disease that was discovered within the chest. The only wonder is, after eleven days exposure of the body at this hot season of the year, that the change of structure was not still more extensive.

Mr. Wilson states that he has dissected, or examined from five hundred to one thousand bodies in the course of his professional researches. I have also served much in warm climates, where deaths are unfortunately very common, and decomposition of the body after death very rapid, and I should say from Mr. Wilson's description, that the change he observed, was merely the first stage of putrefaction, and the ecchymosis around the small muscle nothing more than venous transudation which is apt to take place in congested parts. I regret that I did not witness these changes; and I here repeat my protest against the order which you gave for our exclusion from the examination. You say that you issued that order at the suggestion of the jury, and I was surprised to hear you admit that on the unfounded suspicions of others, you consented to wound the feelings, and attempted to lower in public estimation, the characters of two medical officers of her Majesty's service, as honourable and independent in principle as yourself; and certainly as unprejudiced and disinterested in this inquiry, as any one of the jury.

The first examination of White's body may be called a public one, as I was sent down from London by Sir James M' Gregor's express order to be present at it, and I brought Dr Reid along with me. Had a dozen medical gentlemen wished to be present we should have made no objection, but, on the contrary, should have been delighted to have had the benefit of their opinions.

The second examination was made at your suggestion by a gentleman of honour and known respectability in this neighbourhood, selected by the jury themselves. That examination Mr. Day has told you he had every facility afforded him of making, and he was uninterrupted, as no one, not even Dr. Warren, the surgeon of the regiment, attended; and the only professional person present when he made it was Mr. Mc Kinlay his own partner. So that he had a fair opportunity, the most prejudiced person will admit, of ascertaining the truth.

But when by anticipation you judged the medical evidence inconclusive, and decided on subjecting the body to a third examination, and gave directions to have it exhumed for that purpose, the question assumed a very different aspect. And I think unprejudiced people will say that it would have been more in accordance with our notions of English even handed justice, had you, in place of appointing Mr. Wilson, a personal friend of your own, and Mr. Day the nominee of the jury, either allowed the medical men of the army to witness the proceedings, or named a committee of three medical gentlemen quite unconnected with either you or the case. As the case now stands a private examination was made, and Mr. Wilson drew up a memoir concerning it, *without even consulting his associate*, and Mr. Day has told you himself, that, with the exception of the softened muscle which he observed, he does not agree with Mr. Wilson.

Mr. Wilson's memoir, I admit, is drawn up with ingenuity, but of the truth and value of the novel, physiological, and pathological doctrines that it contains, the medical profession will be better able to form a correct opinion than this *respectable* jury.

Mr. Wilson has also asserted, without any

hesitation, or qualification, that White would now be alive had he not been flogged, and in doing so, I think, he has stepped beyond the bounds that generally restrain prudent and conscientious men and has assumed to himself a knowledge which belongs to Omnipotence alone.

For my own part, I am content to occupy more humble position, and candidly to admit that in a complex science like that of medicine, much must be left to conjecture, as it is quite impossible to define with mathematical precision the predisposing and exciting causes of disease; nor can i reasonably be expected that medical men should do so. All that is required of them in cases like this is, that they should give an opinion to the best of their judgment, founded on their experience in similar cases, and on sound pathology. Acting on these principles I now repeat, that, in my opinion, the exciting cause of the acute disease, which, all the medical witnesses agree, produced White's death, was more likely to have been the considerable atmospheric variation that occurred about the time that he was taken ill than the flogging which he received on the 15th of June, (three weeks before), and from which he is reported by Dr. Warren to have perfectly recovered.

I am not, however, disposed either to deny, or undervalue the well known law of the animal economy, by which the internal parts sympathize with superficial injuries, but then it must be borne in mind when inflammation of internal parts has been set up in this way it has a peculiar character and keeps pace with the external source of irritation, whereas, in White's case, the supposed source of irritation had ceased to act when he was taken ill. The appearance of the parts when examined after death, was that of a recent acute inflammation, not of three or four weeks, but of a few days duration:—there was effusion of serum into the cavity of the chest, and joining together of the pleura costalis and pleura pulmonalis by soft coagulable lymph—two things rarely, or, I believe, never found when inflammation is excited by sympathetic action.

The only chain of connexion that we have between the punishment and the fatal illness of White, is the evidence of privates Matthewson and Riley, who state that they heard him complain of pain in his chest, but as some of Matthewson's assertions have been positively denied by Dr. Warren, the jury must put their own construction on, the value of the remainder. Riley's evidence is confined to one solitary instance, which occurred the second day after White's admission into the hospital, when he complained of a sense of weight between his shoulders, and a burning pain in his chest; but that complaint of burning pain was never repeated, and we have his confession to Matthewson and others that he was quite well a fortnight after his punishment.

One thing is certain, White was apparently quite well on Saturday, the 4th of July. He assisted in cleaning out the ward, and volunteered to wash out an outbuilding of the hospital on that day, two things indicative neither of acute disease, nor of pulpy disorganization of the muscles of his back, and when told by Dr. Warren that he would be discharged to his duty on the Monday following, he made no remark or complaint.

Now, with the thermometer at 88 deg. which it was on the 4th and 5th of July, even light duty might produce sweating and fatigue, and it is possible when so heated and fatigued, that he may have imprudently exposed himself to a current of air. On Monday, the 6th of July, the thermometer had fallen 20 deg.; a variation considerable in any climate, and rarely witnessed, I imagine, in this country. Diseases of the chest were not uncommon during the months of June and July, and one man, Corporal Barnett, of the 7th Hussars has actually died of inflammation of the lungs, in these very barracks since the investigation commenced.

In the Millbank prison, chest affections have been common, and Dr. Baly, the physician of that establishment, in a note, dated the 31st of July, and addressed to me, states,—"Since the commencement of May there have been nine cases of Pleurisy with copious effusion; two cases of Pleurisy with slight effusion; four cases of pneumonia, in two instances combined with Pleurisy, and two cases of acute Bronchitis; making a total of seventeen cases of severe inflammatory disease of the lungs and pleura. I may remark that none of the men affected with these inflammatory affections of the chest, had been subjected to corporal punishment, and that, with regard to the probable origin of their illnesses I have been able to come to no other conclusion than that they were caused by casual chills, which the men were predisposed to suffer from, in consequence of the extraordinary heat of the weather having produced a relaxed and perspiring state of the skin. You are at liberty to make any use you may think proper of the information contained in this note."

I am glad to avail myself of Dr. Baly's kind permission, as it will show you and the jury that complaints similar to those of which White died were prevalent, and convince you that other medical gentlemen, besides those connected with the army and this case, entertain the opinion that they may be produced by atmospheric changes acting on a relaxed and moist skin.

In conclusion I beg to observe that I am not here as an advocate for corporal punishment; for of all the duties that medical men of the army have to perform, its superintendence is one of the most painful. But in justice to the military officers I must add that whenever I have deemed it proper to arrest the punishment for medical reasons and to recommend the man to be taken down my suggestion has been received with apparent satisfaction and acted on instantly.

JOHN HALL.

THE INQUEST AT HOUNSLOW.

(Letter from Colonel Whyte.)

(To the Editor of the *Morning Chronicle.*)

Sir,—I have hitherto abstained from all defence of my conduct with reference to the late court-martial and inquest on Private Frederic White of the 7th Hussars, trusting that when the mass of false reports and distorted facts has been cleared away by time and inquiry, the good sense and feeling of the public could not fail to do me justice, but deliberate false statements made by a recognised authority, such as are presented by Mr. Wakley's address to his jury, cannot be slurred over with out personal denial. I pass over the question as to whether flogging was the cause of the man's death. I leave that to be treated by surgeons in general and the *Medical Times* (Vide *Medical Times* of Saturday, August 1) I pass over the question as to whether it was fitting and decent that Mr. Wakley, utterly throwing aside the opinions of the other uninterested medical men, should recommend the jury to abide by the single opinion of Mr. Erasmus Wilson. I pass over whether it was right that even after Mr. Erasmus Wilson's discovery, the body should be re-interred without at least giving the other medical gentlemen an opportunity of seeing whether it really was a fact that such a change was there or not; and lastly, whether the most general mode of obtaining correct evidence on any point is to question and admit the evidence of the criminals themselves, as was done throughout, in the vast mass of irrelevant matter brought before the inquest. On all these points I say nothing, but leave them to the world and the medical profession to deal with, and pass at once to the broad statement made by Mr. Wakley, in his address to the jury, that in this case *there had been a deliberate attempt to hold back that investigation due to the law, to the regiment, and to society.* We will now see how far this statement is justified. On the morning of the 11th of July, it was reported to me by Surgeon Warren that private White was in a state of danger, from an acute attack of inflammation, that the progress of the disease was rapid, and he feared it might terminate fatally. I immediately desired Dr. Warren to report the facts to Sir James Macgregor, the head of the medical board, and on this report Dr. Hall was sent down. The man died that night. A post mortem examination was then made on the 14th, of which the following is a copy.—[This document has already appeared in our columns.] —On the receipt of this I forwarded it direct to the adjutant general. The ordinary course in the service is to bury men the second day after death, whereas this man died on a Saturday and the application was made on the Monday to bury him. On the *Wednesday* following, or almost five days after his decease (and that in the hottest weather ever experienced in this country), the arrangement for his burial was made, as is usual in the service, by his troop, and an attempt is made to fasten a charge of misrepresentation and concealment on the authorities, because the troop sergeant who bore the application (utterly ignorant of the case), in answer to a question of what the man died, says, "Of his liver;" although in his ignorance he appears to have been as near the mark as Mr. Wilson, in the opinion of other medical men. Still, to prevent any misconception arising from this statement, as I found there were various reports afloat, I sent to Dr. Trimmer a copy of the medical certificate on the post-mortem examination the following morning. It was during the period between the Saturday of his decease and the Wednesday of his burial that the speculation of public curiosity was attracted—not from any suspicions (as the coroner states) in the *regiment* as to the cause of the man's death nor from any suppressed publication of the medical misrepresentations, for which I can scarcely be supposed answerable, as there were no circumstances regarding this man's death that could embarrass a commanding officer. It is quite clear that there could be no necessity for concealing it on the part of the "*people* in the barracks," and it is equally clear that the mystery which the coroner alleges to have hung round the report of this man's death when mentioned at the registrar's office, and to the clergyman, was a mystery that could be traced no further than themselves, and solely of their own creation. Nor am I aware that the inquest has elicited any facts, with the exception of Mr. Wilson's discovery, that the public might not have been in possession of had they applied to the proper source. From the time of the *post mortem* examination, I further beg to say that I placed no bar to the free communication between the soldiers and civilians. The usual ingress and egress to the barracks went on between both parties, which would scarcely have been the case had I been anxious to suppress information. Before the inquest sat I desired Captain Thurley, the senior officer of my regiment, to wait on Mr. Wakley, and give him every information in his power; which was done. And further, I wrote at the same time to Mr. Wakley myself, to the effect that my most anxious wish was to afford the public, the coroner, and the jury, every aid in my power to assist their investigation—stated, although not summoned, I should be there in readiness, and anxious to answer any question that any member of the jury might wish to put, and requested him to read my letter to the court. It however suited his purposes better to put it in his pocket, and not name it until the end of the examination of the second week, when he made casual mention of it. Mr. Wakley appears to think that I ought to have reported and made statements on the circumstances of the man's death, directly to himself and other civil authorities, and by no means seems to divine that my duty, as a soldier, was simply to give a full statement to superior military authorities, and having done so, to act afterwards solely on their orders. Be that as it may, I trust that I have made clear to the public that there was no attempt at concealment on my part or that of the regiment; and, therefore, that his statement on the opening of his address to the jury was utterly unfounded, and calculated to bias most unnecessarily the minds of the jury and the public at large.—Your most obedient, J. WHYTE Lieut. Col. 7th Hussars.—Hounslow Barracks, August 5, 1846.

FROM THE WEEKLY CHRONICLE, EDITED BY MR. WARD, M. P., SHEFFEILD.

Mr. Wakley was elected Coroner on the

strength of two principles—politics applied to procure the appointment to judicial office, and the opinion that a medical man was most fitted to administer the functions of the office: Mr. Wakley has effectually demonstrated the fallacy of the latter proposition, and he has supplied another reason why political feeling should never be suffered to warp the judgment in the choice of an administrator of law.

We do not say this from any jealousy or ill-feeling to the Medical Profession, for it is a noble one—full of many amiable, and learned, and benevolent men, amongst whom we have known, from time to time, one or two, who, to medical knowledge, superadded a legal intellect eminently fitting them for the office, which they could not, and would not but have adorned. Such men, however, could hardly win the attention of a County Constituency, or think of seeking it, except under very unusual circumstances, and we are not called on either to discuss the rule that the office is a legal one, or the exception that to be a medical man is not, in itself, a disqualification; since it is enough, for our present circumscribed purpose, that Mr. Wakley illustrates the rule, in his own person constituting no exception, and that his illustration is sufficiently striking to settle the question of Medical Coronerships for a century to come.

Very advantageously indeed, for himself and the public, might Mr. Wakley exchange a little of his intolerable amount of self-appreciation for a corresponding extent of legal appreciation of the principles of that law it is his luck, or his misfortune, to administer. But as the Court of Queen's Bench has vainly endeavoured to indoctrinate him with a little knowledge of the matter, we shall not attempt the hopeless task for ourselves. But less noise and more decorum,—a sustained gravity fitted to the sadness of the occasion, where the tendency seems to be to relieve deep tragedy by broad farce,—a rigid rejection of self in the constant contemplation of the business, instead of the Royal Victoria pause, which "waits for the applause,"—an inflexible impartiality in the manner, as well as in the matter, in place of the eternal hunting up, and laying out for, popularity, the case, the case and not the Demagogue—surely these things are within Mr. Wakley's reach; and if they are not they ought to be.

Mr. Wakley can go through a case with a dash like the little pony at Astley's through his papered hoop;—he can dodge it, also, as the Clown in the circle dodges the whip: the Inquest on poor Clara Webster is an instance of his first style; the Hounslow Flogging, of his last. We felt sure, from the first, that the melancholy affair would furnish him with the opportunity of keeping himself before the public, *via* the *Times*, for a month; and at the termination what does he? complains of the irrelevant matter introduced, the irrelevancy being all his own!

For intricacy and confusion we pit his examinations against those of Dogberry: "Masters, it is thought that it will go to be proved,"—"Stand aside you, now,"—and "'Fore god, both in a tale!" are nothing to it. We dare say it is all very clever, and that Mr. Wakley has some circumlocutory notion of circumventing somebody by it; but the manner passes all legal comprehension.

Sometimes the proceedings are relieved and the interest revived by the discovery of a mare's nest on the part of the Coroner, as when he fancied, or pretended to fancy, upon some verbal jumble of a witness, that one of the farriers had flogged without orders, and was therefore obnoxious to a charge of manslaughter—a blunder which, if not a mere clap-trap, seems to argue in favour of a military coroner for that special occasion: then ever and anon, Mr. Wakley bursts forth with a letter which he has received, which either ends in smoke, or lets out the interesting fact that he has been pursuing the inquiry out of court. Suddenly, in illustration of one benefit inherent it would seem, to the system of medical coroners, as carried out by Mr. Wakley, a difference of opinion arises between Mr. Wakley and a medical witness upon a question of physiology, pathology, or the like, and next to a religious difference, there is nothing like a scientific one for virulence of feeling. In the present case, a sort of sauce *piquante* is poured over the dish *a l'ordinaire* by the witness complaining of being excluded from the *post mortem* examination, to which the judicial intellect of the Coroner teaches him to reply by the question "What right had you to be there more than any body else?" and by charging the witness with "irregularity" in conducting the previous examination! And lastly, when the whole proceedings become most earnest and grave, a funny question or remark from Mr. Wakley set the whole room in a roar.

It is not wonderful that, with such an example before them, the Jury should forget themselves and indulge in partisan exclamations; and it is not to be expected that the judicious think should attach much weight to the result of an inquiry so directed.

SURGEONS AT INQUESTS.

(To the Editor of the Medical Times.)

SIR,—Allow me to call your attention to the extraordinary inquest lately held at Hounslow which is of importance to every person throughout the country.

By the reports in the papers we find that the medical evidence is directly contradictory, so that one party or the other must have sworn falsely upon the affair.

It requires no extraordinary acumen to see that the coroner endeavoured to make a case of the whole affair—to manufacture something unpalatable to the public—and, knowing that nothing could be done without medical testimony he contrived to procure that also.

He announced that a great man was coming from town. Expectation was excited.

Parturiunt montes nascitur ridiculus mus.'

Talent is invoked, and down comes Wilson. I we look to Wakley's inquests, we always find the modest Erasmus puffed most painfully, which has led many to enquire, is there no compact between them—is there no collusion between the puffer and the puffee?

Erasmus comes and examines the body: others are excluded, except those whom the coroner thinks he can readily overawe by the mighty testimony of the huge Erasmus.

The body is putrid, Wilson finds the cause of death quite apart from the flogging, which much perplexes him. Nothing undaunted, however, this brave man, before the whole country dares to convert putrefaction into a disease, and we find him swearing that the putrid muscle is affected with pulpy softening.

The other medical men whose evidence redounds much to their credit, disclaim "this never a fore-heard-of disease," and swear that it is to be attributed to putrefaction. Erasmus, therefore, stands publicly forwards as either having made a new discovery, or having forsworn himself for a party purpose. Let him now clear his character, or bear the opprobrium.

The fact of a coroner acting in collusion with a surgeon, whom he is endeavouring to puff is extremely important. It involves a very serious principle, for it is very apparent that Wakley and his man Friday can injure any man's character, and rack any man's peace of mind, as the result of their mere whim, or more settled malignity.

Against such collusion, sir, I emphatically protest, and call upon the authorities either to appoint a coroner incapable of influencing his surgeon, or to provide for the summoning of gentlemen who are independent of the will or the whims of Wakley.

I am, Sir,
Your obedient servant,
"A CONSTANT READER."

GOSSIP OF THE WEEK.

ROYAL COLLEGE OF SURGEONS. The following Members of the College having undergone the necessary examinations on the 4th and 6th instant, were admitted by the council on the 12th instant to the Fellowship; viz. Messrs. William Reader Cass, Leeds.—Richard Hunt, Canterbury. Edward Barnfield Gardner, Stroudwater. Joseph Hutchinson, Chatham Hill, Manchester. John Barrett, Orange Grove, Bath. Edmund Boutt, Bath. James Hunter Junr. Milner Sq. Islington, and Edward Newton, Howland street, Fitzroy square.

MEDICAL LEGISLATION.—Mr. Wakley and Mr. Warburton have introduced into the House of Commons a measure copying the registration clauses of Sir James Graham's bill. It has had two readings, but it is expected to proceed no further, from, among other reasons, the late period of the season in which it is introduced. No portion of Sir James Graham's measure received coarser "vituperation" from the Radical Coroner than the registration clauses; and the feeling is universal, if indifferent to this new piece of trickery and distrust of its author.

OBITUARY.—On the 9th instant, at Bath, aged 68, William Rizdon Kebby, Esq., 35 years surgeon in the Ordnance Medical Department.

DEATH OF DR. BOSTOCK.—We regret to record the death of this eminent physician and natural philosopher, who died in Upper Bedford Street on Thursday, the 6th instant. He was a native of Liverpool, and a pupil of Drs. Black, Priestly, and Monro. We shall next week furnish our readers with a memoir.

ILLEGAL PRACTICE OF MEDICINE.—The Faculty of Paris appears to have taken more to heart than heretofore the question of the illegal practice of medicine in France. Since M. Raspail's condemnation, a certain M. R—s, a graduate of Giessen, who was practising under the cover of his purchased degree, has been condemned to a fine of 200 francs. These fines may appear of no importance, and, in fact, to be a sort of evasion of the laws; they are, in reality, a pro forma punishment; but a repetition of the offence is visited with imprisonment. It is fair and just that the interests of public health should be cared for and protected—it is just that the very existence of men who have laboured hard for the acquirement of their profession should be under the shelter of the law and that M.Ds. by purchase be not allowed to endanger by their ignorance the lives of confiding patients. At the same time that we fully assent to the justice of the punishment inflicted upon Raspail, we cannot but deplore that so great a mind should have been found compelled by want to descend to the tricks of charlatanism.

MORTALITY TABLE.

For the week ending Saturday, August 8, 1846.

Causes of Death.	Total.	Average of	years.
ALL CAUSES	1135	898	968
SPECIFIED CAUSES .	1130	892	961
Zymotic (or Epidemic, Endemic, and Contagious) Diseases ..	345	201	188
SPORADIC DISEASES—			
Dropsy, Cancer, and other Diseases of uncertain or variable Seat.........	142	99	
Diseases of the Brain, Spinal Marrow, Nerves and Senses	157	155	157
Diseases of the Lungs, and of the other Organs of Respiration	215	227	294
Diseases of the Heart & Blood-vessels..............	31	23	27
Diseases of the Stomach, Liver, and other organs of Digestion	125	87	72
Diseases of the Kidneys, &c. ..	10	6	7
Childbirth, Diseases of the Uterus, &c.	11	9	10
Rheumatism, Diseases of the Bones, Joints, &c.	12	6

No. 360. SUMMARY. Aug. 22.

PROGRESS OF MEDICAL SCIENCE,

INCLUDING CHEMISTRY AND PHARMACY.

[From our own Correspondent.]

ACADEMY OF SCIENCES.

Meeting of August 10. M. MATHIEU in the Chair.

TREATMENT OF ANEURISM BY GALVANISM.

In a former number we recorded one case of cure of aneurism of the temporal artery, by M. Petrequin. That gentleman now presents to the Institute a case of popliteal aneurism equal in size to a hen's egg. The cure was complete in ten or twelve days. The rest of the meeting was consecrated to subjects foreign to medical science.

ACADEMY OF MEDICINE.

Meeting of August 12, 1846; M. ROCHE in the Chair.

A letter was read from Dr. Junod, recommending the use of his metallic exhausters in the first stage of typhoid fever. This method, according to its promoter, Dr. Junod, would combine the advantages of preventing local congestion, and of relieving many of the symptoms without acting directly upon the inflamed intestine, and without causing debility from loss of blood.

Another letter was read from Dr. Aubert Roche, requesting permission to communicate to the meeting some facts connected with the incubation of the plague. Permission was granted.

THE EPIDEMICS.

M. Dubois (of Amiens) read an official report on a paper, by M. Castonnet, entitled "An easy Method of Preparing a general Topography of the departments of France." In this paper the author reproaches the society with negligence in reporting on papers relative to epidemics. M. Dubois proved that M. Castonnet was in complete ignorance of the habits of the Academy, and that all the useful documents were employed. The report was adopted.

A VACANT SEAT IN THE ACADEMY.

After a short debate the Academy decided that the next nomination should take place in the section of Materia Medica.

THE PLAGUE.

M. Aubert Roche observed that the twenty-ninth conclusion of the report clearly implied that the incubation of the plague never exceeded eight days. On a former occasion M. A. Roche had before had an opportunity of defending this opinion before the Academy. Great stress had been laid in the general debate on the analogies between typhus, the plague, and yellow fever. This objection should be met with a very simple answer, *i. e.*, that these maladies differ from each other as much in symptoms and appearance as in their producing cause. The analysis of the cases opposed, since 1841, to the doctrine of the eight days' incubation, demonstrates that errors have always been committed in favour of the contagionists, who believe in a protracted incubation. M. A. Roche concluded that on this period of eight days' incubation might be based all the new reforms introduced in the quarantine system.

M. Hamont was of opinion that it was perfectly proved that the production of the plague constantly depended upon local causes of insalubrity. He did not believe in the pestilential constitutions, admitted by the commission; and thought that the Academy should add to the first conclusion of the report the statement that the plague yielded to sanatory improvements, and especially to lazarettos. Meeting adjourned at a quarter to five.

HOTEL DIEU.

CLINICAL LECTURE ON INTERMITTENT FEVER, BY PROFESSOR CHOMEL.

Essential intermittent fevers are exclusively observed in predetermined circumstances. They are always produced by special agency, such as the accumulation of stagnant waters either on the surface or beneath the level of the soil. These fevers strike on entire populations, reappearing every year at the same period when the earth is damp. Epidemic intermittents thus developed cease to exist when the ground becomes dry. This theory of the production of these diseases is now a fact admitted on all hands. When not occasioned by these atmospheric conditions the ague shows itself only seldom. Thus in Paris, where the disease is not common, it was frequently observed in the neighbourhood of the little river Bièvre, before that stream was excavated and walled in. The direction of the winds must also be taken into consideration in the history of the causes of ague. In this country the westerly winds are chiefly observed to blow when intermittent fever becomes epidemic.

It is not during the coldest weather that the ague makes its appearance, nor is it during the excessively hot days of summer, but when, in consequence of the intense heat, a portion of the liquid elements of marshes is absorbed, leaving a muddy deposit on the fenny surfaces. In very cold climates, and also in very hot climates, intermittent fevers are not common. Particular individual circumstances also exist, rendering the human subject more apt to receive the infection. Thus, during the night, miasmatic principles are more easily absorbed, probably on account of the condition of the frame during sleep. Weak persons, and those whose blood is impoverished by repeated venesection, are much more exposed than strong, robust individuals. We have said that in Paris intermittent fever is rather uncommon, and yet it is impossible to visit any hospital without meeting with some cases; thus we have at present in the wards a patient labouring under the ague. the disease was not caught in Paris, but in Africa. This you will observe in most of the Parisian patients affected with fever. They have brought it from another part of the country. Some years since we attended a lady recently returned from Poland, whence she had brought the infection. Most of the country places in the neighbourhood of Paris are tolerably healthy; yet the late construction of railways and of the fortifications have occasioned many cases of intermittent fever. In many subjects, however, it is extremely difficult to detect the determining cause of the malady they are affected with, but, even in doubtful cases, marshy miasmata must undoubtedly be considered the cause of the symptoms. The period which elapses between the action of the causes and the outbreak of the first paroxysm varies considerably, and cannot even be determined by approximation. The febrile attacks, isolately considered, present two distinct forms, designated by the words—normal and abnormal paroxysms. The former are constituted by three distinct periods, called rigor, calor, and sudor. This is fortunately the most common form. The duration of each stage is generally one hour or half an hour, and the calor and sudor generally last longer than the period of cold. Together with these modifications in the temperature of the body, are observed many functional disorders, such as sickness, headache, lassitude of the limbs, and in almost all notable changes in the composition of the urine. These phenomena are sufficiently well known to permit us to dispense with a lengthened description. The paroxysms never last beyond twenty or twenty-four hours; when they have passed twelve hours they may already be considered as unusually long. The first attack is followed by the period of intermitting, during which the patient thinks himself perfectly cured; but a second paroxysm soon occurs, the ague consisting only in a succession of alternatives of illness and apparent health. Secondary symptoms soon are produced by the repetition of the paroxysms. These secondary phenomena consist in the change of the complexion, and in the more or less considerable increase in size of the spleen. The liver is sometimes also hypertrophied, and œdema shows itself in the extremities, produced by compression of the abdominal veins by the large viscera, or by the impoverishment of the blood. The intervals between the attacks constitute the differences of type. Thus the fever may be quotidian; it is tertiary when it reappears every second day; quartan when forty-eight hours separate the attacks. Double tertiary is that fever which occurs every day, but with a degree of intensity which is the same only every second day. Other fevers have been also admitted—double quotidian, double tertiary, double quartan These fevers seldom can be referred to essential ague. they belong more properly to symptomatic febrile excitement. Quintan fever, in which the paroxysms only occur every fifth day, has also been admitted, although it is observed in Europe only by exception.

HOSPITAL BEAUJON.

M. Robert.

Retention of Urine—Puncture of the Bladder.

J. K., aged sixty-nine, of a good constitution, was admitted into the hospital on the 1st of May. He denies having ever had any venereal disease, and says he always enjoyed a good health up to the spring of 1844, when he was attacked with cerebral congestion and temporary paralysis of the right side of the body. The excretion of urine is slow. On the 29th of April, 1846, after a repast, during which he did not commit any excess, he found it impossible to evacuate urine. During the ensuing night the bladder remained distended. On the next morning a catheter was introduced, and the operation was repeated in the evening with a tolerable degree of facility. On his admission into the hospital, the abdomen was considerably distended, and the hypogastric region quite dull on percussion. Pressure of the abdomen permitted the distended bladder to be detected. Examination of the perineum showed the presence of considerable swelling in the prostate gland. Vain attempts were made to introduce metallic catheters, or even gum bougies of the smallest diameter. After each attempt a small quantity of blood oozed from the urethra. Pulse was 90; the skin was cool, and the tongue moist. Fifteen leeches were applied to the perineum; the patient was placed in a bath, and poultices applied to the stomach. In the evening fresh and vain attempts were made to introduce a catheter. On May the 2nd the face was red, tongue dry, pulse at 110; a few drops of urine had been passed. The catheter being again vainly employed, venesection ad ℥ xvj was performed, and the patient was placed in a bath. On May the 3d the urine had not yet been evacuated, the bowels were confined, the tongue dry, and the pulse 120. Finding the introduction of the catheter impossible, Dr. R. resolved upon performing puncture of the bladder, and the operation was at once instituted. A curved trocar being passed into the bladder immediately above the symphysis, two quarts and a half of brownish and fetid urine were extracted, and the canula of the trocar was maintained in its place with an appropriate bandage. In the evening the pulse fell to 110, the tongue was dry, the bowels confined, and during the night agitation and subdelirium were observed. During the following days the condition of the patient gradually improved, the scrotum became, however, slightly œdematous from its contact with urine. The canula, having been accidentally removed on the 12th, was replaced by a fine bougie, which served as conductor to replace the tube. On May the 17th, the patient was again seized with unpleasant symptoms, which were removed by the exhibition of saline purgatives. On the 5th of June the patient left the hospital, the abdominal wound being perfectly healed.

The Spas of the Rhine, by Professor Trousseau and Dr. Lasègue.—(Section 5 continued.)

During the second stage of hypochondriasis the patient for the first time, besides dyspeptic accidents, experiences erratic spasms, which would escape his notice if he was not interrogated on the subject. Thus he complains of cramps in the lower extremities, involuntary trembling of the hands, tremulous movements of the eyelids. The internal muscles are occasionally the seat of spasms, deglutition becomes difficult, palpitations of the heart are observed, and the bladder contracts involuntarily. This character distinctly points to what is generally called nervous complaints. But it is important to remark that the symptoms occupy the nervous system only in a secondary manner: they were abdominal, and now become general; their seat, *not their nature*, is modified. It is on the progress of the symptoms that chiefly rests the success of treatment. At this period, when the malady has not yet fixed upon any special organ, it is still easily cured. Hitherto the patient had only resorted to the resources of nature; he now seeks more efficient assistance. The curative indications are not here the rigorous consequences of the facts. No critical phenomena to be encouraged by the physicia[ns] have yet appeared. Later, piles, intermitten[t] diarrhœa, congestion, and nervous manifestation[s] show to what natural derivation the patie[nt] is predisposed. It is in the stimulation [of] the secretion the most favourable results ar[e] to be found; but, as observation teaches us [that] nature proceeds in the most fortunate cases, it als[o] informs us the temporary amelioration [is] not to [be] trusted. To be really efficient, inte[rn]al super secretion must be prolonged, and introduce into th[e] system a new habit. Fr. Hoffmann, who fir[st] established the reputation of acidulated and salin[e] spas, was in the habit of prescribing in cases [of] hypochondriasis the water of Eger-Toplitz, [or] even Selters. The experience of modern times ha[s] not contradicted the opinions of Hoffmann. Col[d] spas are generally preferable. The water may be mixed with milk; baths and enemata should als[o] be recommended. The great advantage of th[e] waters containing chlorate of sodium, Hombourg, Kissengen, and Manheim, is the slow modificatio[n] which they produce in the general health. In thi[s] respect they are far better than alcaline spas, th[e] energy and activity of which may be productive o[f] inconvenience. Many physicians think the patient[s] should be prepared by an appropriate method [;] others neglect this precaution; and in the hypothesi[s] of the German school phlebotomy and local ab[s]traction of blood are particularly beneficial. Bu[t] repeated abdominal evacuations lead by anothe[r] road to the same result: abdominal plethora vanishes, and the equilibrium is re-established. Add to the precious resources of mineral spas, th[e] horse and coach exercise, amusement, company, [a]nd the example of other patients, and you hav[e] obtained the most excellent of all medications. A[t] first the diagnosis of hypochondriasis is attended with no sort of difficulty; but in proportion as the disorder advances, extends its branches in all directions, and loses the precision of its contour, the diagnosis becomes attended with much greater difficulty. The first termination of hypochondriasis resides in hemorrhoids. In this crisis the prodromic signs of the molunen hemorrhagicum are distinctly observed: spasms become limited, and the pain localized. We are far from believing that all cases of hypochondriasis terminated in piles; but we are satisfied that the hemorrhoidal discharge is a frequent consequence of the disease. When the piles have appeared in consequence of other complaints they should not be suddenly suppressed; their suppression, notwithstanding modern theories, will be the cause of most variable disorders. In such cases mineral waters, containing salt and carbonic acid, are productive of the most satisfactory results. The weakest of the waters should be used in plethoric cases, such as spas of Soden and Hombourg, Wiesbaden, Kreutzenach, and Kissingen. To Manheim, on the contrary, should be sent the individuals who are not threatened with internal congestion or excessive depletions. Should the piles increase in intensity, so as to constitute a complication of too great severity, the spas of the Rhine should not by any means be recommended; they might cause increased suffering. Some physicians, considering that the natural production of hemorrhoids proves advantageous in hypochondriasis, have proposed artificially to produce hemorrhoids by the use of stimulating applications, aloes, &c. Let us say at once that this method has never been successful. It is no more in our power to create hemorrhoidal congestion without the hemorrhagic molunen, than it is to recal the menses if the movement of the blood does not direct it towards the uterus.

Hypochondriasis is frequently terminated by nervous accidents. Every one has observed the melancholy and the sort of insanity to which the hypochondriac patient has given its name.

Hysteria was long considered to be a form of hypochondriasis, and this confusion was sanctioned by the authority of Sydenham and the writings of R. Whitt. Here again particular symptoms point beforehand to the direction the disease will ultimately follow. Paroxysms of essential asthma or neuralgia, alternating with functional disorder, will enlighten the prognosis; to these cases the saline mineral waters are quite applicable, and should be employed at an early period; but minute examination is necessary, as those waters will serve only to increase essential neuralgia or even symptomatic forms of nervous suffering. Thus asthma is improved at Hombourg, Kissingen, and Weisbaden; but all asthmatic patients should not indiscriminately be sent to the duchies of Nassau or Baden. This would be the place to study the cerebral consequences of hypochondriasis. The timid insanity is the most common; some fear their friends, others their enemies, others their disease. The consumptive patient knows of his fatal complaint only the pain and oppression; the hypochondriac, on the contrary, undergoes a malady none of the symptoms of which escape him. When the patient is in the incipient stage of insanity, cure the hypochondriasis and you will at the same time cure the delirium; when matters are more advanced, should even the original complaint disappear, madness shall remain; it is become habit, necessity; we can no more say of it, "*sublatâ causâ tollitur effectus.*" Gouty affections sometimes terminate in hypochondriasis. We shall leave the study of gout for a special chapter.

The fourth and last form consists of exaggerated or diminished secretions. Constipation usually attends this disease, and at irregular intervals, it is replaced by a frequent though not abundant diarrhœa. These accidents are extremely rebellious when they occupy the urinary organs; gravel is their inevitable consequence. Finally, hypochondriasis is, in our opinion, a real malady—*the pathological unity of which is demonstrated by the unity of the treatment to be employed.*

Gout—(Section 6).

Sydenham, when affected with the gout, comforted himself with the reflection that it is a disease special to men of art and to great people. It does not appear, however, that this compensation is sufficient to all gouty subjects, or that it ever makes them forget their sufferings. Rich, for the most part, they shrink from no sacrifice, and submit cheerfully to the roughest treatment, when it holds out a hope of cure; but the specific, that *rara avis in terris*, which would be productive of a fortune to its discoverer, is still to be found. Specific medicines are the gift of chance, and experience regulates their use. It is not the most learned who make the discovery, and, consequently, it is not necessary to be learned to make it. With these unfelicitous hopes have mineral waters been often applied to the treatment of gout. The rapid perturbation or the slow revolutions which they bring on in the constitution have been enthusiastically cried up as infallible; but the progress of the cases now shows the fallacy of those promises, and, disappointed in their hopes, the patients obstinately revile those spas to which they came confident of a complete cure, and where they might have obtained partial relief. The consequence is that in this matter absolute opinions have carried the day, although truth is certainly on the side of less exclusive doctrines.

Let us begin by stating that, in our opinion, no single mineral water enjoys specific properties against gout: many are useful, many injurious; none answers in all cases, or deserves the title of specific. This conviction will readily account for our mode of appreciating the virtues of mineral waters. We shall endeavour to detect in gout what is not itself to distinguish its complications. The successive elimination of symptoms belonging to the main complaint is one of the most delicate applications of therapeutics.

Gouty subjects have long since been divided into two great classes: cases of atonic gout, and cases of acute or tonic gout.

Tonic gout is that which is most generally described. It is easily observed: its progress is regular, its paroxysms are short, very painful, but they are separated by intervals of complete calm, and reappear only at distant intervals; often the articulation of the big toe is the only one affected. Paroxysms are chiefly observed at night, they diminish and cease even in the morning, and return the following night with equal violence: fever is often present, and always redness and œdema of the affected part. It is readily conceivable that this form should have been confounded with arthritis,

and that pathologists should have hesitated to grant to it more general influence than to any other articular lesion. But the mistakes in therapeutics soon pointed out the pathological errors. Medications, instituted without discrimination and carried on without precaution, proved that this was not a simple local alteration in which the organic functions remained unconcerned. In tonic gout the characters of the atonic form are met with diminished in importance: it is a difference in degree, not in nature. The premonitory symptoms are general, and do not point to the exact delimitation of future symptoms; although the articular inflammation becomes regularly localized, still it can always change its seat and recover its natural mobility.

It is a fact of undoubted experience that the danger of gout is always proportionate to its tendency to displacement. Preoccupied with the pain, the patients are not of that opinion: they measure the importance of their case to the intensity of their sufferings. The physician employs another measure, and knows when it is necessary that he should prescribe a violent pain in order to remedy a fatal condition of the system. In cases of tonic gout, patients solicit entire, even immediate, relief; they do not believe in its dangers, and the prudence of their physician is called incapacity. We cannot, therefore, determine with too much circumspection the circumstances in which we may accede to their wishes, and those, on the contrary, in which we must refrain.

In tonic gout patients are generally plethoric; a luxurious mode of life, sedentary habits succeeding to active occupation, too great indulgence in the pleasures of the table, have been considered by all pathologists as the chief producing causes of the disease. On these etiological data have been founded the therapeutical indications. Thus, when the attacks become intolerable, plethora is first to be destroyed; active exercise, severe regime, and fatigue, even succeed in diminishing the intensity of the crisis, and ensure long intervals of repose. The debilitating waters of Ems would in such cases, therefore, be useful; it is not the gout which is improved, but the gouty diathesis—a distinction which will appear subtle, but which is not without importance. The patient is charmed with the relief he has obtained, he continues with perseverance the use of the waters, paroxysms do not return, the plethoric state has ceased; the patient, in a word, seems cured. But the physician must not permit himself to be led astray by these fallacious hopes—the disease has only changed its nature; it was local, it is now diffused: a tonic gout has been produced, less severe in appearance, more dangerous in reality, because it has less tendency to become localized. Everything here depends upon the measure of the treatment: the pains should be diminished, but on no account entirely removed. Unfortunately we have on this point no precise rules for our guidance; tonic medicines soon give rise to characteristic appearances. Not so with debilitating drugs. Under these circumstances excessive reserve is only a fair degree of prudence. But we have other documents which permit us more easily to foresee the facts and to observe them. The accessory symptoms of tonic gout have not the same uniformity as its essential characters. Thus age is a consideration of some importance. Tonic gout occurs frequently in young, plethoric subjects. The privation of movement is insupportable to them, feverishness is frequent, and preliminary congestion generally violent. Is there, in appearance, a more favourable condition for the exhibition of the alcaline mineral waters? And yet in no circumstance is caution more necessary.

All physicians know that subjects affected during youth with gout die young. They seldom resist an affection which older subjects bear without much danger. Local gout does not kill: it never endangers life so long as it returns to the joints. Therefore the prognosis must be more severe in young men, because the disease has a tendency to displacement—a fact proved by daily observation. Constitutional plethora is an attribute of mature years; in youth plethoric congestion is incomplete and transitory.

If mineral waters really cured the gout and destroyed the diathesis, perseverance in the treatment would give many chances of success. But we can advise the spas of Ems and Vichy only on the condition that their exhibition be limited by the strict rules of prudence. It should be better to abandon this treatment when it is impossible to direct it oneself than to risk the substitution of atonic for tonic gout.

DAN. M'CARTHY, D.M.P.

ORIGINAL LECTURES.

A COURSE OF LECTURES ON PRACTICAL MIDWIFERY.

By EDWARD RIGBY, M.D.

Fellow of the Royal College of Physicians, Senior Physician to the General Lying-in Hospital, Lecturer on Midwifery at St. Bartholomew's Hospital, Examiner on Midwifery to the University of London, &c.

Delivered last session at St. Bartholomew's Hospital, and revised by the Professor for the "Medical Times."

At the close of my last lecture, gentlemen, I was engaged in explaining to you the importance of ascertaining that the uterus has contracted firmly after labour. I told you that this was a duty never to be neglected, and I explained to you that your patient could never be considered safe from hemorrhage until the womb was firmly contracted. I told you also that there was no necessity for the escape of blood externally, in order to place your patient in a most hazardous condition, but that internal bleeding might be going on insidiously, and I endeavoured to impress on you the state of the uterus felt through the abdominal walls by which this condition might be known. I will briefly recapitulate the leading points, bearing on this subject. If after the birth of the child, and before the expulsion of the placenta, the uterus feels large and flaccid, you may be sure some mischief is going on; if on the contrary you feel the organ hard, firm, and about the size of a fœtal head behind the pubes there is no chance of hemorrhage being actually present. Still however the organ may become relaxed and bleeding may come on insidiously, so that it behoves you to watch your patient with the greatest care, and frequently to examine whether the uterus continue contracted. After the expulsion of the placenta, if the uterus be firmly contracted it will be felt behind the pubes about the size of a cricket ball, and quite hard, and as long as it continues in that state, no hemorrhage can take place.

After the birth of the child, the placenta sometimes follows immediately, occasionally even it is expelled at the same time with the infant. Generally, however, a few minutes intervene after the severe pain which expelled the child before the uterus again contracts, during which period it seems to be in a state of inaction. You will therefore wait a few minutes, when you will generally find the uterus again begin to contract, and the dull and peculiar pains, which accompany the separation of the placenta begin. These as I have before told you, are called the dolores cruenti. Sometimes they may not begin for some time after the birth of the child, and it appears that the period of their occurrence is much influenced by the rapidity or slowness with which the uterus has been emptied. If then the uterus continue hard and contracted, and there be no hemorrhage, even although the dolores cruenti do not commence for a short time you should wait, and when the pains do come on again, if you run your finger along the cord you will most likely be able to feel its insertion into the placenta. If this be the case you will know that the placenta has been detached, and has partly or wholly passed the os uteri, when it will generally be expelled by the contractions of the vagina.

If, however, hemorrhage take place before the commencement of the dolores cruenti, you must lose no time in waiting, but you must adopt some means by which to make the uterus contract, because you know that to induce firm contraction of the uterus is the only means of ensuring the cessation of the hemorrhage. In such a case as this, of course plugging is out of the question, as sufficient blood may escape into the cavity of the uterus to cause your patient's death: under these circumstances you should give your patient a wine glassful or two of cold water to drink; you should open the doors, and fan her face, or suddenly sprinkle a little cold water in her face. These means will produce a sudden shock, which if the case be a slight one, will generally bring on uterine contraction, when of course the hemorrhage will cease. If your hand be cold you should apply it with the fingers spread out over the abdomen and endeavour to grasp the womb with it. This measure very often succeeds in exciting the uterus to contract when on introducing your finger into the vagina, you find the placenta thrown off.

When in a case either with or without hemorrhage your patient, gentlemen, begins to feel pain, and you, on passing your hand over the abdomen feel the uterus beginning to contract, and feeling hard it will become necessary for you to examine the placenta, and if you can feel, on running your finger up the cord, its attachment to the mass, it will become your duty to assist in its expulsion. In doing this, you must bear in mind the different directions of the axes of the pelvis. Remember that the axis of the vagina and the axis of the os uteri are very different, and that therefore if you make traction on the cord in the axis of the vagina you are, as it were, pulling round a corner; you thus lose a great deal of your extracting force, and run no small risk of tearing off the cord at its insertion; besides which, by pulling the cord against the os uteri instead of directing the placenta through it, you irritate the os uteri very considerably, so as to induce it to contract irregularly, causing what has been called hour glass contraction. I have been called up oftener in consequence of retained placenta from this cause than from any other. When you commence removing the placenta, therefore, you must bear in mind that the axis of the vagina and the axis of the os uteri are nearly at right angles. You must remember the direction the cord takes and having twisted it round your left hand run the fore finger of your right hand along it, and use this finger as a pulley, to change the direction of the extracting force, and thus pull downwards and backwards. You will find, gentlemen, by this means that very little traction will be requisite. The placenta will come through the os uteri without any difficulty, and then of course its expulsion will be quite easy. In many cases you will find that even when the os uteri is contracted round the cord, by steadily keeping up gentle traction for some time the contraction will yield and the placenta will come away gradually. It sometimes happens however when the hemorrhage is severe that more active measures are required, and you will be sometimes called on to introduce your hand into the cavity of the uterus, and detach the placenta. This subject however will come under our consideration hereafter, when speaking of dystocia. When the placenta comes into the vagina you must be in readiness to receive it, and then as it approaches the os externum, twist it round two or three times: by doing this you will twist the membranes into the form of a cord and bring them away entire with the placenta; you will thus avoid tearing the membranes and leaving any shreds adhering to the interior of the uterus, a matter of some importance, as such shreds are apt to cause a good deal of irritation, with putrid discharge and fever. In twin births the placenta will be of course much larger and it is necessary for you to bear this in mind, as in case of hemorrhage the bleeding surface will be much more extensive, and the loss of blood consequently more rapid. In extracting the placenta of twins you should be particularly careful not to use extractive force until they are detached and about to enter the vagina as from no greater size of the contained mass the uterus must necessarily remain larger than after a birth of one child only: the organ will therefore be more liable to inversion from any undue force applied to the funis. Your best plan of proceeding will be to twist the cords together and thus

apply an equal degree of force to each placenta, and as the placentæ come down they should be grasped by the hand and rotated as before mentioned, which will materially assist in detaching the membranes from the uterus should this not be quite completed.

In former times, gentlemen, it was the fashion to bring away the placenta immediately after the birth of the child; I need hardly stay to point out to you the objections to this mode of proceeding.

As soon as the labour is over and the placenta expelled, it will be proper for you to have the wet things removed from under your patient, which will be easily done by the nurse without disturbing her, and a warm napkin applied to the external parts. She should then be allowed to rest for about half an hour, and even to enjoy a little sleep. At the end of this time, during which the nurse should be employed in washing and dressing the child, you will take care that a broad and firm bandage be duly applied and pinned firmly round the abdomen so as to give support to the abdominal organs. This bandage may consist of a jack towel or of a piece of calico, and if the abdomen has been much distended during pregnancy, or if the labour was one of twins and there is any tendency to hemorrhage, two or three folds of a soft napkin should be laid under the bandage in the region of the uterus to increase the support of the part. In many cases of twins it is advisable to apply the bandage immediately after the birth of the first, in order to assist in the expulsion of the second child. As soon as the child has been washed I invariably have it applied to the breast You are aware, gentlemen, of the sympathy existing between the uterus and breast; and you will not therefore be astonished when I tell you that the application of the child to the breast produces permanent contraction of the uterus and consequently does away with all danger of hemorrhage. I have found the application of the child to be the strongest possible stimulus to uterine contraction, and I have never seen a case in which hemorrhage has occurred after its taking the breast fairly for a few minutes. The only case of hemorrhage some little time after labour, which I have had of late in my own practice, was one in which the mother did not intend to suckle her offspring, and consequently the infant could not be applied. The child should be allowed to remain at the breast about five minutes, after which the mother should be encouraged to take three or four hours rest On her waking from her sleep the child may be applied to the breast in the regular way. The mother's breast, gentlemen, is the proper place for the newborn infant, which, according to the investigations of M. Milne Edwards of Paris, possesses much less power of generating animal heat than the adult. Besides this, all young animals naturally seek the warmth of the mother. On the other hand, however, I am far from being an advocate for the child's being constantly permitted to lie by the mother's side; the proximity makes it restless, and induces it to long for the breast at unseasonable hours From the first I think the child should be accustomed to take the breast at certain stated periods; about once every two or three hours perhaps, and the mother should accustom it to an absence of at least four or five hours during the night. You will find attention to this point very important in practice, as by means of it you always obtain four or more hours for your patient during which she can rest undisturbed.

I am happy to say, gentlemen, that the practice of mothers suckling their own offspring has become much more frequent of late years than it was some time since, and I rejoice that the practice continues to increase The celebrated Boer of Vienna, says on this subject, "Every mother who has been strong enough to carry and nourish her child during the nine months of pregnancy, is also strong enough to afford it the breast for some time after birth." Cases however occur in our artificial mode of life in which this is not invariably true. Still however the mother should suckle her own infant in every case in which it is practicable. Dr. Conquest my predecessor in this chair, gentlemen, says in speaking of the necessity of suckling, "A very serious evil arising from a woman neglecting this imperious duty is, the probability of her becoming more frequently pregnant than the constitution of most females can sustain without permanent injury. A woman who suckles her children has generally an interval of a year and a half, or two years between each confinement; but she who without an adequate cause for the omission does not nurse, must expect to bear a child every twelve months, and must reconcile her mind to a shattered constitution and an early old age."

You should never allow anything to be tied tight round the child's body, one reason for this is, that the fœtal circulation is apt to return if there be any obstruction to free respiration; besides this the child will never sleep well, unless its limbs are free. Nurses are constantly in the habit of bandaging the little creatures round quite tightly, and they require to be actively looked after in order to prevent them from indulging their propensity in this way; they generally consider it a great innovation to permit the infant to have the free use of its chest and limbs. Without this however, gentlemen, I need not tell you the child must, apart from more serious evils, become irritable from the discomfort occasioned by restraint, and from want of sleep. In some parts of Germany they mummify the infant completely by bandaging it from head to foot, rolling in its arms and rolling its legs together, so that in fact only the head is left free, and the infant is formed into a solid mass incapable of motion by bandages I will now, as I have nearly finished the subject of actual natural labour, give you a few plain hints respecting your conduct towards your patient, and as Dr. Dewees has given some excellent directions on this head, I shall quote some of them, recommending at the same time his whole chapter on the subject to your attentive perusal Dr. Dewees says, "1st. Let all communications of a delicate nature be conducted by a third person, the nurse, when present should be that person; in her absence any elderly friend."

"2ndly, Endeavour by a well chosen conversation to divert the patient's mind as much as possible from the object of your visit, when your services are not immediately required."

"3rdly, When your presence is not absolutely necessary in the sick room, be as little in it as will be consistent with your duty to your patient; by this you will remove restraint and apparently abridge the period of your watching."

"4thly, Should the situation of the patient in your opinion require to be ascertained let the proposition be made by a third person, as the nurse, and urge in defence of the request, all the circumstances which led you to believe it would be important, as the length of time she had been in labour, the force and frequency of her pains; the evacuation of the waters, if it has taken place, and above all to ascertain the progress of the labour, and whether the presentation be a proper one"

"5thly, If after you have made your examination you should be importuned for your opinion of the nature of the presentation, and the duration of the labour, do not commit yourself by any positive declaration unless you are certain of the first and pretty sure as to the latter."

"6thly, Before you proceed to the examination, let your patient be placed with the most scrupulous regard to delicacy, as the slightest exposure is never necessary."

Early sucking is of the utmost importance on many accounts; and the nurses now a days, at least in London and its neighbourhood, do not so much object to it as they did formerly. I have already given you one reason for the early application of the child to the breast;- viz., the increased safety to the mother which follows it by the firm contraction of the uterus, which it induces Another reason for it arises from the form of the mother's breast. At this period the breast is soft and conical, and the nipple prominent, and the child is easily able to pull it out; whereas if you wait till the breast becomes distended with the milk, the nipple is shortened and the breast hard and flat, so that the infant will not be able to draw out the lactiferous tubes, without biting the nipple, by which means it becomes excoriated. At first the breast is conical, and the nipple easily taken hold of; besides this, if the child be not applied the milk secreted is reabsorbed into the system, and milk fever is set up. This milk fever, gentlemen, has been erroneously supposed to be necessary to the first secretion of milk; it is no such thing, however, for the breast contains milk immediately after the birth of the child. It arises from the absorption of the secretion, and its being thrown back again into the circulation. When the child is applied early to the breast, the mother never suffers from distention or milk abscess; when the child is applied directly, it will take the breast much more readily also, as its instinct is very strong at this period; indeed, it shows this by sucking at anything in its way, even its own finger. Besides this the early milk is thinner than that secreted afterwards, and more fitted for the food of a newly-born infant, and from being of a purgative quality is well suited to purge away the meconium, which the child's bowels contain; and it is, therefore, never necessary to shovel castor oil down its throat for this purpose. Such proceedings as giving the infant sugar and butter, castor oil, &c., cannot too much be condemned; they set up gastric irritation, and in the end produce aphthæ, &c. Generally speaking, the first attentions the infant receives on entering the world, are a series of outrages on its comfort and health. Generally speaking, the first thing the nurse thinks of is to souse some spirit over the unfortunate little thing's head—very pleasant treatment for a creature just come into contact for the first time with the external air, to whose delicate skin the spirit must feel like so much melted lead, and shortly afterwards be followed by a sensation of cold as intense. Then it gets a dose of castor oil; next it is washed; then it is powdered; then it is dressed; and then it gets a large cupful of pap shovelled down its throat, which it must swallow or choke. After this the child becomes flatulent, and then we have dill water, or gin and water administered. What wonder then after this treatment that the infant gets thrush?

Whether there be milk or not the child should be put to the breast immediately. As regards the smegma with which the newly-born infant is covered, it is secreted for the protection of the skin; and as it is secreted by the sebaceous glands, it cannot be removed by soap and water. The best plan of removing this secretion is, by beating up a little butter without salt into a liniment, with a little white wine. This may be smeared over the parts, and when the child is afterwards placed in warm water, the smegma comes off easily.

At our next meeting, gentlemen, we shall commence the subject of the mechanism of parturition.

The Nature, Causes, and Treatment of Mental Diseases.

By M. PINEL, M D., Member of the Academy of Medicine, formerly Physician to the Bicêtre and Salpêtrière Asylums, Author of the "Traité Medico-Philosophique sur l'Aliénation Mentale," "Medicine Clinique," "Nosographie Philosophique," &c &c. Translated, with Notes, illustrative of some important Doctrines in Physiology, Phrenology, and Moral Education,

BY DR. COSTELLO,

Principal of Wyke House Asylum, Editor of the Cyclopædia of Practical Surgery, &c.

V. SEROUS CONGESTIONS OF THE BRAIN.

Hydrocephalic Œdema.

After sanguineous congestions, the most frequent affections of the brain are lesions of secretion.

In the acute stupor of the insane we have seen the effects produced by an excessive accumulation of fluid around the encephalic mass on its functions; suspension of the intellectual faculties, of the will, speech; cataleptic rigidity of the movements, insensibility of circumscribed portions of the skin, and of the mucous membranes; the serous fluid in

filtrates into the cerebral pulp, and when the substance is sliced, small drops are seen oozing out, and these become more numerous when pressure is made. This œdema coincides with an accumulation in the arachnoid and in the other cavities; it may occur after an attack of apoplexy in persons whose constitutions are predisposed to serous effusions, and often occurs while resorption is taking place after sanguineous effusion.

When its progress is acute, it may simulate the effects of an apoplectic attack, the accumulation of the serum occurring as a sudden effusion; there is loss of consciousness, paralysis, and coma. It then often happens that the lung becomes congested, the breathing stertorous, and death takes place promptly. This is what was called by the ancients serous apoplexy.

In its chronic form we find all the symptoms formerly noticed in the stupor of the insane, which are those of general, but gradual, compression of the brain, and which is rarely fatal.

Acute Hydrocephalus.

Acute hydrocephalus is very frequent in children, the serum being accumulated chiefly in the ventricles. We have somnolence or coma from which the patient can be roused; he appears to hear although he cannot speak, understands what is said, and puts out his tongue. He can eat and drink, although coughing is excited from a difficulty of deglutition, which appears to depend on a degree of paralysis of the pharynx. If we have the convulsions of trismus, or other serious symptoms, it happens in consequence of the serous effusion becoming complicated with encephalitis or arachnitis. Where the latter complication takes place we have all the cerebral symptoms belonging to inflammation of the brain—headache, continued fever with paroxysms, convulsions, delirium, and vomiting. The disease lasts from ten to thirty days, and is almost always fatal. We sometimes see this hydrocephalus supervene in the last period of cerebral, tubercular, or encephaloid degeneresceence. There is another kind of apoplectiform hydrocephalus that occurs in children weakened by antecedent maladies, more especially the scrophulous, phthisical, or leucophlegmatic: it comes on without other premonitory signs than depression, headache, and drowsiness; often even these signs are wanting, serous effusion taking place into the cavities, and the patient becoming unconscious and comatose. Slight convulsions occur, with illusions of sight; the eye is fixed, the pupil dilated, and the retina insensible. This disease is readily distinguished from cerebral hemorrhage and softening, from the paralysis being never complete, and from the intellect resuming power from time to time. We see some children, especially in the leucophlegmatic state that succeeds scarlatina, suddenly seized with complete blindness, dilatation of the pupils, and slight convulsive movements. These symptoms announce an instantaneous serous effusion into the ventricles, a species of hydrocephalus which yields readily to the use of revulsives, diuretics, and purgatives.

Chronic Hydrocephalus.

This disease depends almost always on an arrest of development of the nervous centres. Breschet affirms, on the authority of a great many autopsies made by him at the Foundling Hospital, that in the fœtus in children born at the full time, and at the age of six and twelve months, he has found a true hydrocephalus in the anterior and median ventricle, or septum lucidum. When its causes are not congenital the child seems to be predisposed to the affection by a general lymphatico-scrophulous constitution, which shows itself by the size of the head, a certain precocity of the intellectual faculties, and an anormal development of the limbs. The state of the encephalon in hydrocephalus varies; for the most part the liquid is accumulated in the ventricles, distending their walls, unfolding the convolutions, and converting the brain into a thin pouch, in which it is difficult to distinguish the white or grey substance. Sometimes the encephalon remains in a rudimentary condition, the cerebrum and crura are entirely wanting; and the pons varolii, irregular and knobbed, is the only nervous centre that can be found at the base of the brain. Instead of the rest of the brain we have nothing but liquid. In other instances there is but one of the hemispheres wanting, and in some rare cases the brain appears to have but one cavity, and to be formed of one hemisphere. The symptoms of hydrocephalus in the child are ushered in by enfeeblement of the senses, listlessness, loss of memory of words, habitual drowsiness, momentary catalepsy, vertigo, severe pain in the head, and disturbed vision; according as the fluid accumulates the intellectual faculties grow weak, the muscles of the face and eyes are agitated with convulsive movements, speech is uncertain, the tongue can only stutter and sometimes appears entirely paralysed, the muscles waste, slight convulsions supervene, and the evacuations are involuntary. All these symptoms are sooner or later followed by complete idiocy, blindness, dumbness, and deafness. Deglutition becomes difficult, the hands and feet cold, and sudden congestion puts an end to this miserable existence.

Hydrocephalus presents itself under three different forms: first, with diminution of the size of the head, a form that is always congenital. The fontanelles are formed, and the sutures ossified; and when this is the case, the accouchement is quick and easy. The children almost always die on coming into the world, or soon after, of convulsions; the head is pointed at the top, and depressed at the forehead and sides; the eyes insensible to the light, and in a state of continued convulsive rotation; the head is in continual motion from right to left, or from before backwards; and the limbs are contracted. In the second form the head is often of the usual size; the disease, too, may be congenital, although it usually occurs at a pretty advanced period of life. This is the cephalic dropsy of Selle, and its symptoms are similar to those which depend on an extreme size of the head. In the third form the dimensions of the head are singularly augmented; when the disease is congenital, it renders the accouchement difficult, or even impossible without perforation. But if the head be not too large at birth, its size increases rapidly in the early stages of infancy. The parietal bones are thrown outwards, giving the cranium an extent disproportioned to that of the face. The globes of the eye gradually lose their mobility, the pupils enlarge with a squint upwards; at a later period, the eyes move from one side to the other like a pendulum, and the loss of smell follows that of sight. Whilst, as a contrast, the hearing remains very acute; and, in the early months, the patient starts convulsively at the slightest noise. At last this sense becomes obliterated like the others; the mouth remaining open, and the saliva flowing from it. Those who, in spite of this advanced state, still retain any intelligence, give expression to their emotions of joy, anger, or fear, by repeatedly jumping on their chair, their feet extended, the arms hanging down, and the fingers flexed in the form of a cup, and they laugh or cry vehemently. The direct cause of hydrocephalus and all its accompanying symptoms is the congestion of fluids, serous, sero-purulent, or purulent, in the cavities of the skull, and producing lesions of the nervous system; the predominance afterwards of exhalation over absorption keeping up the symptoms. As to the anatomical alterations, they may be referred to three different states of the encephalon. First, to the arrest of its development, or the absence of some of its parts; secondly, to the distension of the cerebral pulp and the enlargement of the ventricles from the presence of the fluid. Thirdly, to the presence of serum in the space between the two folds of the arachnoid. The first of these states belongs to the early stages of fœtal development. The second, to a more advanced stage of uterine life, all the parts of the encephalon being completely formed; but the fluid not being sufficiently absorbed, compression takes place, but the individual may live. The effusion which occurs in the arachnoid coincides with complete development, and may date from the earliest period of infancy. Besides the general debilitating causes, the most common are the compressions made by mothers on the abdomen to conceal pregnancy, and hence it is that women who give birth to the largest number of hydrocephalics are the unmarried. The termination of this disease is always fatal, and those who exist with it for a time present all the symptoms of imbecility and idiocy. We may even refer to it as the sole cause of congenital idiocy.

VI. Organic Degenerescence of the Brain.

The lesions of congestion and secretion in the nervous centres are not confined to those already mentioned. Under certain circumstances and the influence of causes peculiar to each individual, the nervous molecules may disappear, and be replaced by accidental products of the same kind as those that are developed in the lungs, liver, and other viscera; the most frequent are tubercles and cancer.

1. *Tubercles of the Brain.*

In form, texture, and structure, the tubercles of the nervous centres are similar to those of other organs; they have been found in all parts of the cerebro-spinal axis, in the hemispheres, above the walls of the ventricles, in the optic tracts, the corpora striata, in the inferior convolutions, in the valve of Vieussens, in the cerebellum, and cervical portion of the medulla. They are more frequently encysted than in other parts of the body, they vary in size from that of a millet seed to that of a hen's egg; an entire lobe may be transformed into a tuberculous mass. Most commonly, they exist in numbers of small size, and coexist with tubercles in the lungs. Louis has remarked that whenever tubercles are found in any other organ, they are never wanting in the lungs.

The nervous pulp surrounding them may remain quite healthy; it is very difficult to distinguish it from the tuberculous matter, being alike in colour. It may, however, have undergone various alterations, such as simple injection, softening, induration, or depression of the convolutions. The membranes are thickened, adherent to each other, injected, and presenting serous effusion; according to A. Latour, such effusion is large around tubercles, or in the meninges in young children; and the acute hydrocephalus is often the consequence of such tubercles manifesting their existence by symptoms of meningitis. They are developed in the nervous pulp indolently, independent of any external influence, and are the result of a perversion of the functions of nutrition and secretion. They chiefly affect infancy from the ages of four to twelve; their progress is insidious, often giving rise only to slight, intermitting headache.

According to their seat, however, they give rise to paralysis, contracture, convulsions, or epileptiform attacks. The intellect is rarely much disturbed; the sight becomes weak or lost.

The progress of tubercles is slow, being quickened from time to time by acute symptoms of delirium and convulsions; their most frequent termination is in hydrocephalus or meningitis; coma and death then follow quickly. Wherever their seat may be, the symptoms they produce are those of compression and irritation, which they determine in the nervous fasciculi affected, and it is from the diversity of these effects that the different lesions of motion and sensation result. A patient with tubercles in the cervical medulla has been known to die in fits of hydrophobia.

2. *Cancer of the Brain.*

This is much more rare than tubercles, and depends also on a general cancerous diathesis. Cerebral cancer varies in size. Sometimes the surrounding brain is healthy, or reduced to a jelly. The meninges are also sometimes affected, becoming injected, inflamed, thickened, and at last presenting the cancerous alteration in greater or less extent; it may be even extended to the skull, and in this manner cases have been observed where cancer of the brain coincided with cancer of the ear, of the ethmoid bone, of the nasal cavities, of the globe of the eye, and of the optic and olfactory nerves.

It has been remarked that a similar relation may exist between cancer of the testicle and cancer of the brain; in several instances the amputation of a sarcocele has been followed by cancerous points developed in the brain and spinal marrow. The

cancerous diathesis is fully as positive as the tuberculous.

Intelligence and motility are affected in the same way as in other affections of the brain. The sensibility, however, shows some symptoms characteristic of cancer: there is violent headache recurring for years, sometimes at the point of disease, sometimes at the opposite point of the head; the pain is lancinating, and shoots to the skin of the face or other parts of the body. The cutaneous sensibility is exalted or wholly abolished; sometimes the itching on the skin is intolerable. The senses are successively paralysed.

M. Rayer has seen several cases of cancer of the pituitary gland, the chief symptoms having been a sense of weight in the head, amaurosis, failure of memory, coma, headache during several years, and contraction of the limbs. The failure of the memory in such a disease is a functional disorder deserving of notice.

In cancer of the cerebellum there are epileptiform convulsions, the head is thrown backwards, there is loss of memory, and the patient walks like a person in some degree intoxicated. When cancer affects the mesocephalon we have singular movements of the eyes, numbness of the limbs; severe pains in the soles of the feet, calves, and knees; with loss of taste and smell, coinciding with unimpaired hearing and intellect.

The other organic alterations that may affect the brain are calculous concretions, fibro-cartilaginous productions, divers cysts, adipose productions, osseous growths, and entozoa of different kinds. These organic degenerescences are very rare; their symptoms are the same as those of all the important chronic alterations of the brain, and vary with the extent, seat, and progress of the organic deformation itself.

VII. General Relations of Alterations of the Brain with its Diseases.

The organic causes which give rise to all other diseases are found in affections of the nervous pulp: abstraction being made for the moment of its intellectual, motory, and sensitive functions; and, taking its anatomical structure alone into consideration, we have seen that its tissue becomes congested, irritated, inflamed, and disorganized, like all other tissues of the body.

Moreover, the absence or excess of sanguineous or serous congestion may, as in other tissues, be a determining cause of morbid modifications. I the brain sanguineous congestion is what sudden blushing is on the face; it colours, and swells it and has a tendency to disappear unless there ha been a violent irruption of blood in the peripheri or central cortical substance, and then it produces very serious symptoms.

There is the same difference between congestive and inflammatory irritation that there is betwee the fire that burns and the fire that does not burn. Another element is necessary to convert sanguineous congestion into irritation and inflammation, and this element physiologically can only be had from the lesion of the extremities of the nervous fibres of sensation. So long as the congestion remains confined to the capillaries, there is only redness and obliteration, but when it extends to the nerves of sensation, then there is pain, efflux of fluid, exaltation of function, in a word, inflammatory irritation, the progress of which is regulated by the well-known general laws of augmentation, exacerbation, stasis, decline, and termination.

In pathological affections of the brain the elements and principles are the same. Inflammatory irritations in the nervous pulp determine the symptoms that are most characteristic of all inflammations. 1. *The redness*—It varies from a rosy hue to deep purple, or colour of wine lees; the difference of vascularization of the white and grey substance causes the difference of their respective shades. The fibrous structure of the white substance makes it less prone to sanguineous congestion, and hence it is that almost all the acute diseases of the brain begin in the peripheric cortical substance, which, through the pia mater, is in direct and constant relation with the elements capable of irritation. In acute delirium, acute or chronic cerebritis, we have met almost always with acute or chronic lesions of the periphery. 2. *The heat*—It is only necessary to place the hand on the forehead, or on the top of the head, to perceive that the heat of the brain is considerably augmented—the common expression is, "My head burns." 3. *The pain* is also shown in headache, sense of weight, and fixed pain. 4. *The tumefaction* is obvious in the convolutions, and throughout the cortical substance, the thickness of the latter being doubled, and being, as it were, granulated and fleshy; the middle layer especially, which appears to contain an enormous quantity of vessels, presents the most marked alterations of redness, consistence, softening, and size both in the acute and chronic state.

These four phenomena, redness, heat, pain, and augmentation, constitute in the brain true local fever, which afterwards shows itself externally by all the ordinary febrile symptoms. It has been said that insanity is an apyretic disease: it is like most other diseases that have passed into the chronic state, such as the chronic exanthemata of the skin, &c. But at its commencement it presents the most decided febrile symptoms: augmentation of the heat, circulation, and colour of the face, to such a degree as to be called cerebral fever. All inflammatory action alters the tissues, and this can be shown more readily in the cerebral pulp than elsewhere. The nervous pulp at first increases in bulk and weight, but it rapidly loses its cohesion; and hence the softening, induration, and partial or general atrophy, which it presents in its chronic diseases. As to the hypertrophy of the white substance in the acute form, as we have met with it in paralytic cerebritis, we must admit that the serum performs the same part in this fibrous tissue as does the blood in those tissues to which it has free access—that is, that it augments its bulk by congesting the capillaries with serum, and producing all the effects of an inflammation which we must call white in contrast with common inflammation.

In acute delirium we find injection of the pia-mater and of the cortical substance. Sub-arachnoid ecchymosis of a deep red, with dotted injection, and often softening of the cerebral surface. These alterations are more decided in the acute or paralytic cerebritis; there is redness, thickening or opacity of the arachnoid, softening of the cortical surface in certain points without adhesion; in other points, adhesion of the pia-mater to the cortical surface, and, in addition, deep softening of the cortical substance.

In the chronic state, the thickening of the arachnoid, the dilatation of the vessels of the pia-mater and of the cerebral substance, show plainly the gravity of the process of congestion and irritation which marked the acute stage. But while the symptoms have abated, a congestive process of irritation, and an organic one of absorption, succeed. The cerebral substance diminishes in quantity, certain convolutions waste, the ventricles enlarge, the cortical substance loses its colour, hardens, and at last disappears.

In the brain, therefore, the acute or chronic symptoms correspond with the acute or chronic lesions of the nervous pulp; when the alteration is local and superficial it causes but a slight cerebral disturbance of the intellect, the locomotion, or the sensibility. When it is more extensive, and penetrates more deeply into the cerebral mass, the disorder of these three functions is more decided. The delirium becomes complicated, with lesion o the movements and the sensibility, as shown ir durable symptoms, as in paralytic cerebritis. When it attacks at the same time the sensitive and motory fasciculi, whose connection is so intimate throughout the entire mesocephalon, and the progress of the disease is more or less acute, we observe all the spasmodic and convulsive affections, and in the state of chronicity and intermittence we have epileptic and hysterical symptoms. In order to the production of convulsions there must be a simultaneous lesion of motile and sensitive nervous fasciculi or fibres.

VIII. Reactions, or Visceral Causes.

Amongst the physical causes of cerebral affections, the reactions of the viscera are important to be observed. The general effect of these reactions is less to disturb the intellectual acts themselves than the manifestation of those acts, that is to say, the manner of being or of acting, the mode of thought or expression, or what we call, in one word, the character or disposition of each individual.

In the circulatory apparatus we may remark certain influences of the lungs and heart; the lungs of themselves have but little sensibility; but when there is inflammatory congestion of their tissue, a dull, pungent, unaccustomed pain, announces to the brain a malady of these organs. The attention then begins to reflect on the necessity of breathing, and on the dangers as well as benefits which life derives from it. If these organs continue to be altered into a compact mass unfit for respiration, if almost all the air-cells are obliterated by the hepatization, the anguish of imminent suffocation is redoubled, the intellect itself is deranged, and a delirium of several days blots from the patient's memory the imminence of the danger which he has run. In chronic affections of the lungs, the slow and profound disorganization of phthisis, their reactions on the brain have a peculiar character. It is by illusions of health and high hopes, and dreams of a long future, that they hide from the intellect their fatal *denouement*. Phthisical persons, in the very last state of marasm, still lull themselves in the most chimerical projects up to the very moment of death. The lungs alone, of all the viscera, possess the privilege of these happy illusions. Is it because of their being placed on the confines of the life of relation and organic life, to use Bichat's expression, and of being exempt from appetites and desires, that they are spared the pain of those desires, the perversion of which reacts painfully from all other sources upon the brain?

In the heart the slightest modifications affect the intellect; as soon as its contractions become stronger, more accelerated, and the circulation consequently more active, the brain experiences an excitation which gives more energy to its thoughts, more resolution to its acts; it is in this sense that we must understand the popular expressions, *hearty, having heart*. But when the organ acquires a morbid development, as in hypertrophy, its influence on the brain becomes morbid also. The intellect derives from it a singular disposition to outbreaks of passion, exasperation, and the most violent agitation from the slightest causes. It would seem as if the tissue of the heart itself had become a perpetual focus of obscure and painful feelings, conferring on the intellect an habitual moroseness and an unwonted irascible violence. Such are the vague reactions that some patients cannot account for at the commencement of organic lesions of the heart. When the disease is confirmed, these symptoms diminish in intensity, returning in the night in regular attacks, and almost at fixed hours, with violent throbbings, painful palpitations, and a suffocation and anxiety which suddenly banish sleep. When the attack is not sufficiently strong to rouse the patient from sleep, the paroxysm reacts upon the intellect in frightful and sinister dreams, the impression of which pursue him through the next day.

We here observe that the disease of a distant organ becomes for the brain a permanent source of obscure sensations, which produce a series of ideas and determinations, more or less bearing on the internal pain which excites them. In the digestive apparatus these reactions are more energetic. The stomach in its natural state, and under certain circumstances, is the seat of wants and voracious appetites which, as in the case of the shipwrecked seamen of the Medusa, may degenerate into a real phrenzy. In certain affections of the stomach, bulimia, for instance, one can scarcely credit the impulses to which such an appetite gives rise. "I saw a woman at the Salpetrière suffering from this complaint, under whose pillow it was customary to place several loaves during the night; the bread having been forgotten on one occasion, she devoured several pieces of skin and muscle from her arm. She had prostituted her person solely to get bread; and at last, so great was her horror of hunger, that she committed suicide.

The slightest derangement in the digestive func-

tions immediately causes a sense of weight in the head, inaptitude for labour, and drowsiness. In chronic gastritis one cannot describe that diversity of illusions of taste and smell which ascend incessantly to the brain, becoming for that organ an obscure cause of internal sensations that are always false. When the chronic affection extends to other digestive organs, the pains increase in intensity, and the sufferings are more deep-seated and undefinable, and hence result a general depression, the most chimerical terrors, the most singular illusions of pain, often even a disgust of life and a desire to die. This distress is but too real, but it reaches the brain as a false interpretation, and we may recognise in these reactions the symptoms of a slight hypochondriasis. In scirrhous affections of the stomach, the brain receives a continuity of impressions of suffering which betrays itself in habitual sadness, a biting sourness of repartee, a hostile disposition that delights in contradicting everything, in seeing everything under false colours, and in construing everything in a bad sense. The reactions of the organs of generation show themselves on the intellect of a woman at the age of puberty. The approach and return of every menstrual period powerfully influence her character, which becomes modified, irascible, unhappy, and the entire body more irritable. This is the prelude to the energetic reactions to be afterwards developed by pregnancy, for then the generative apparatus becomes the seat of a concentration of new forces, extends to the whole organism the effects of its singular influences. In the stomach the appetite is null, depraved, insatiable, and followed by violent vomitings which do not impair the health. In the heart there are lancinating pains and tumultuous palpitations. On the brain the effects of these uterine influences are still more remarkable. The intellect obeys ideas and influences which it cannot understand, and acts which it cannot resist; and frequently the ideas and conduct become sufficiently irrational, and persist for so long a time as to present all the symptoms of a real insanity. Some women are completely insane at each pregnancy, or for a limited period of each pregnancy.

LECTURE XX.

POMPHOLYX, PEMPHIGUS, MILIARIA.

As proposed by Willan and others.

PEMPHIGUS P. Simplex P. Diutinus P. Miliarius	Localis Generalis	Solitarius Sparsus Confertus Acutus Chronicus

GENTLEMEN,—The three cutaneous affections which constitute the subjects that I have proposed should successively follow those which have already engaged our attention, are maladies of which, perhaps, less is known than of any others of equal importance which afflict humanity: I allude to the complaints medical authors have designated *Pompholyx*, *Pemphigus*, and *Miliaria*. This want of knowledge on these subjects arises, I may observe, from three principal causes: first, the rarity and often evanescent nature of the diseases; second, their frequent complication with other maladies of the skin or internal organs; and third, the want of accurate and precise descriptions in those authors who have observed the disease. My own experience, considerable as it has become in the class of diseases forming the subject of these lectures, is yet very limited in these extraordinary vesicular complaints, which, as it were, render manifest to the eye the internal burnings complained of by the sufferers, in a manner precisely similar to that which is evinced by the actual application of fire to the surface of the body, inasmuch as a vesication of greater or less extent is always apparent.

Without further preface, however, I shall endeavour to bring the little knowledge I possess on these diseases into what I trust you will consider useful exercise, by an attempt to simplify the subject; an end it is hoped to accomplish by comprising the three affections under one common description. A reference to the chart before you will at once demonstrate the manner in which this is proposed to be done; and I will briefly put you in possession of the reasons which have influenced me in hazarding the proposition. In the first place most dermatologists, from Bateman to Biett, Rayer, and Cazenave, have either considered pompholix and pemphigus as synonymous terms, or have repudiated the existence of one or the other as a distinct idiopathic affection. In the next place the descriptions of miliaria appear to me to be those of pemphigus occurring during existence of inflammatory or typhoid fever in the system; and that, therefore, it can have no more claim for distinct consideration than eczema, erysipelas, or petechiæ, would be entitled to under similar circumstances; and, lastly, I have thought that, by enlarging the sphere of description of one of these diseases, by admitting into it other similar or identical affections, I should thus multiply the points for observation, and by such means ultimately obtain data for a more clear, and at the same time comprehensive, knowledge of the malady.

With your permission, therefore, the term *Pemphigus*, as adopted by the French writers, shall be applied to this genus of cutaneous complaints, which will be distinguished by symptoms corresponding to the following definition:—Thus I shall consider pemphigus, a non-contagious inflammation of the skin, characterised by eczemation, or the eruption of vesicles, from the size of a millet-seed to that of a walnut, filled with a semi-transparent yellowish liquid, occurring on slightly raised, round or oval, red patches of the cuticular surface; the redness and vesication being nearly simultaneous, and the former not extending much beyond the boundary of the latter. These vesicles, which may be solitary or confluent, and appear suddenly or in succession, terminate by the effusion of the liquid they contain, and by the formation of a thin crust or superficial excoriation, which is ultimately followed by a reproduction of the epidermis. When the crusts furnished by the chronic forms of pemphigus are examined by the microscope, adventitious membranes, or the rudiments of their formation, can be frequently detected, as evidenced by capillaries, filled with blood discs, pursuing a more or less tortuous course amid the coagulated and concreted secretions.

Pemphigus, as above defined, is a disease which may attack any period of life, from the newly-born infant to old age; and it may be complicated with most other diseases of the skin, or with visceral affections of various kinds, particularly those of the liver; in all such cases, however, it cannot be regarded as an idiopathic affection. When speaking of eczema in a former lecture, I then mentioned the aptitude of the human skin to assume what has been called vesicular inflammation, or eczemation, when irritated either from internal or external agents; and the disease under consideration may be held to be the most marked exemplification of this fact or cutaneous law; but I must not omit to remark that constitutional cachexy or idiosyncrasy, consisting in languid capillary circulation, must be present in every case, though it may arise from opposite causes, for example, from repletion as well as inanition of the vascular system. You will perceive, by the chart before referred to, that I have considered pemphigus to consist of three varieties, which I have named—*P. Simplex*, which comprehends the common form of the disease, which, for the most part, supervenes during the existence or at the decline of some other malady, but may exist alone as an idiopathic affection; *P. Diutinus*, which is a more chronic form of the complaint, the eruptions of vesicles being successive; and *P. Miliarius*, which is a vesicular rash occurring during fevers and acute diseases, and seldom attaining, in the size of the vesicles, anything approaching to what is sometimes witnessed in the former species; these three species may be local or general, and they may appear in a solitary, scattered confluent, acute or chronic form.

The eruption may also be ushered in by previous symptoms strictly appertaining to the disease and its varieties, as uneasiness, pain, and irritation in the parts about to be affected, with more or less constitutional sympathy, as thirst, dry skin, feverishness, &c.; whilst in some rare cases it may happen that few, if any, of these symptoms are observable before the appearance of the eruption. Yet, as each variety of the disease is founded on some usually observed peculiarity as regards the symptoms I have mentioned, it may be well to give each of them a brief, separate consideration. *Pemphigus simplex* is characterised by a simultaneous or successive eruption of blebs or vesicles on one region, or over the whole body, which may attain the size of a pea to that of an egg, or larger, when the vesicles become confluent; this eruption is generally preceded by more or less constitutional disturbance, and by oval or round red patches on the skin, which accurately define the future size and position of the eczemation. In a few instances, however, one or two of these spots do not become the seat of vesication, at least it is never observed; but the epidermis is found detached and readily removable even in these situations, and, therefore, it is probable that in the night, or during the hours of repose, a vesicle may have formed, and have become broken and discharged its contents. Each bleb is surrounded with a narrow line of bright redness, the surrounding skin being free from the disease; after a short time the vesicles appear to attain their utmost limit of distention, no two having precisely the same magnitude; in this state they are semi-transparent, being filled with pale yellow serum, like the contents of a burn or blister; and they then burst, sometimes in such a manner as to perfectly discharge their contents; at others a small opening gives exit to a portion only of the liquid, which then becomes turbid, and the cuticle containing it constitutes a flaccid and wrinkled sac, half filled with fluid. In a few days a thin imperfectly-formed brown crust occupies the site of the vesicle for a week or so, when the complaint finally disappears But there may be a succession of similar eruptions, so as to protract the malady for a month or more; this will then refer it to the next variety, for which I have adopted Willan's designation of *Pemphigus diutinus*, successive chronic or lingering bleb, which in reality differs very little from the foregoing species, save in the circumstance which has determined its appellation; as it may persist for months or years, and is, in fact, one of the *most obstinate and rebellious diseases of the skin*. The vesicles are seldom larger than a hazel-nut, and mostly of an inferior size; and they are usually neither so round nor prominent as those of the former-described variety. This disease may also be more strictly considered a disease *sui generis*, as not necessarily attended by the constitutional or organic maladies which are not unfrequently witnessed in the same case. It is, moreover, rarely, if ever, accompanied by any other cutaneous affection, the irritation of which more commonly gives rise to the ephemeral eczemation, characterizing *Pemphigus simplex*. *Pemphigus diutinus* never leaves, but may usually be studied in all its phases on the same subject, each successive eruption of vesicles beginning before its predecessor has taken its departure; the inflammation is also more violent in this chronic form of the complaint, and more apt to assume a purulent aspect, so as to be distinguished with difficulty from impetigo, as in the example of the little patient I have now the opportunity of introducing to your notice, as a well-marked instance of *P. diutinus*, and whose case I shall presently relate.

It has several times happened in the case of this

boy, and it may often be observed in the variety of pemphigus under consideration, that the mucous membranes of the mouth and fauces are attacked with the vesicular eruption, and there is sometimes reason to think that the whole intestinal canal may be more or less implicated.

I may also mention that one or two solitary or insulated blebs of large size (the *Pompholyx solitarius* of Willan) may appear in either of these described species of pemphigus, which may be transitory or acute if belonging to the first species, and successive or chronic if to the second; but I consider the *mere size* of the bleb a circumstance of too trivial importance whereon to found a distinct species of the complaint, as no practical fact indicating the adoption of a different mode of treatment is attached to the appearance in question.

We have now arrived, gentlemen, to the third species of the malady before us, which I have termed *P. Miliaris*. It consists in the eruption (for the most part very suddenly) on any region of the body, of grouped or disseminated vesicles, varying from the size of millet-seeds to that of a pea, and occurring for the most part during fevers or other diseases attended with profuse perspiration, their situations like herpes, to which, indeed, I consider they are closely allied, being over some nervous centre or trunk, the ramifications of which they commonly follow. In a few rare instances the entire surface may be affected, when it would resemble the accounts tradition has handed down to us of several epidemic disorders which have raged at former periods – the sweating sickness of our own country, which occurred in the fifteenth and sixteenth centuries, being amongst the number.

In hot climates, particularly in those where pellagrous affections are common, in Lombardy and other parts of Italy for example, this miliary vesicular eruption is very common, and has been considered to be a true exanthematous fever by M. Penolazzi, who has described it in a well-written paper, published in "The Ann. Univ. di Med., April, 1844." If this be the case, which I consider doubtful, this is certainly not the moment or the place for its consideration, as chronic cutaneous diseases alone form the subjects of our present contemplation. I have seen *P. miliarius* occur in numerous acute diseases, as well as fevers; for instance, in rheumatism, in puerperal peritonitis, during dentition, &c., and also from confining the sick in heated, ill ventilated apartments; whilst the exhibition of opium, mercury, iodine, cubebs, ammoniacal medicines, and other substances of a heating or stimulating nature, have constantly produced it in certain idiosyncrasies.

It must be obvious, from the circumstances now stated, that with ordinary attention there can exist little or no difficulty in distinguishing pemphigus from all other cutaneous diseases; indeed its characteristics are so marked, when the bullæ are unbroken, that, unless in the case of blisters artificially produced, it resembles no other manifestation of cutaneous inflammation. The large vesications attending some forms of erysipelas being readily distinguished from pemphigus by the great tension, redness, and tumour of the part affected, in addition to the very marked difference existing between the attacks, progress, and consequences of the two diseases. Again, the marks left by pemphigus differ from those remaining after eczema or herpes, with which complaints only they might by possibility be confounded, in having a dusky red hue of long continuance, and a more or less circular figure, which is as it were placed in the middle of the sound skin, the line of demarcation between one and the other being well defined, instead of being gradually shaded off, as observed in the last-mentioned affection; while there is little if any regular crust or scab, the loose, imperfectly formed concretions of pemphigus, adherent only by a point, being seen in its chronic forms alone, and manifesting, as I have before observed, when examined by the microscope, an attempt to form a new organization or false membrane, rather than the solid lymphatic encrustations of eczema, which are mostly composed of layers of coagulated albumen, firmly adherent to the parts beneath. It will be obvious, I should imagine, from what has been now said, that pemphigus cannot be a serious disease when it appears in an uncomplicated form, and that, in the latter case, our diagnosis must be founded rather on the nature of the complication than on any danger to be apprehended from the complaint, independently considered; its appearance may, however, like that of rupia, the subject of my last lecture, be deemed an unfavourable indication of the state of the general health, and of want of stamina in the constitution. Of course, this remark has more particular reference to *P. diutinus* of the arrangement we have adopted, for *P. simplex* may be produced from the irritation of common scabies, lichen, or other irritating diseases of the skin wherefore, little importance can be attached to the appearance of this variety under ordinary circumstances, from which fact, indeed, Willan designated the species, *Pompholyx benignus*.

Now, with respect to the treatment of pemphigus, the local measures should be mildly palliative and the internal remedies must be directed to a removal of the cause, whether that be disorder of some particular organ, or a cachectic state of the constitution. The warm bath has been lauded by all writers on this disease as amongst the most useful means of soothing any existing irritation, and of equalizing the cutaneous circulation; whilst quinine, decoction of bark, of the vegetable bitters, and the mineral acids, with opium, are the general remedies most constantly required; it is also often of service to give purgatives and diuretics in the cases, so as to solicit, as it were, other organs to take upon themselves an increase of function, to divert the deranged or excessive action of the skin. A residence in a high situation, a dry atmosphere and nutritious food, with a fair proportion of sound wine when obtainable, are also efficacious agents, the employment of which will, perhaps, lead to fewer disappointments than any others I can mention.

I shall not detain you long by reciting instances of pemphigus, as there is no special treatment required. In the *simple species* (*P. Simplex*) of the disease, a few weeks for the most part suffice to witness its origin and disappearance without the use of remedies; and I have never found *any treatment* of marked advantage in *P. Diutinus* particularly in its inveterate form, where more or less scabious crusts are visible, as in the case of the boy now before us. As models of each variety of this disease have been prepared for your inspection, I shall prefer the citation of the cases to which they belong, though they do not present the marked features of some of the cases which have heretofore applied for relief; but, as I before observed, instances of pemphigus are so extremely rare, that out of nearly 3,000 patients entered on our books during the past year, there have not been more than eight or ten characteristic examples of the disease, and of these the plurality have occurred in the summer season, when our modeller was not at hand.

The model I first submit to your inspection is that of a little girl named Ellen Townsend, aged six (No. 6803), who from her infancy, that is to say since she was two years old, had been suffering from lichen conferus, the appearance of which (for you will perceive it still exists amongst the vesicles of pemphigus) would lead me to infer that it was tainted by congenital syphilis. This little patient was admitted on the 14th of last month only, and the model was taken on the 28th, very opportunely for the illustration of this lecture, which you are aware comes under our consideration as *P. Simplex*, an eruption of pompholyx benignus of Willan supervened as a complication with the original disease, which you are aware comes under our consideration as *P. Simplex*. The relative who attended with this child stated that a similar appearance had on one or two previous occasions presented itself, though never to the same extent; the modeller has shown rather too much redness around the blebs of yellowish liquid; but this I must tell you is necessary, or the colour flies in such a manner as to render the model useless till retinted; you must bear in mind, also, that the pemphigus appeared in the midst of the lichenous eruption, so that greater visible inflammation of the skin was present than is often observed in pemphigus simplex. The bullæ, you will notice, vary from the size of a small bead to that of a horsebean, and they are irregularly distributed; yet in one or two situations they might be confounded with herpes circinatus (of which I shall shortly speak), from their having a somewhat circular arrangement, and also from their position following the distribution of the cutaneous nerves of the thigh and abdominal parietes. This child was taking mercurials in small doses, and also using a lotion containing gr. ss. of the bichloride to an ounce of water. I therefore, in the absence of any other exciting cause that could be recognised, felt inclined to attribute the pemphigus to this origin, which would render it a sort of monstrous *Eczema mercuriale*. There must, however, have been some constitutional peculiarity in the case, as such remedies are in constant and daily use by every one, and such results are rarely encountered. The treatment adopted was to suspend all the means which might be supposed to stimulate the cutaneous circulation; the larger blebs were directed to be punctured with a needle, and powdered starch applied as a dressing by means of a down puff. As some disturbance of the system and feverishness were present, an ordinary saline febrifuge mixture was prescribed, containing a little nitric ether, and the child was purged with Epsom salts and magnesia. In the event of the eruption increasing, she had directions to come here for a mucilaginous bath, and to take an antimonial emetic; for neither of which, as she yesterday told me, had there been any occasion, the pemphigus having very nearly disappeared: the lichen, though better, still remains for future attention.

This case very well illustrates the most usual form of pemphigus simplex. I am sorry I have no recent example to refer to of the affection when strictly idiopathic; but no practical difference exists between the two cases, so that I shall briefly mention the next variety in a form that is sufficiently rare, and, I regret to say, one which has always resisted every kind of treatment I have hitherto employed; a circumstance equally deplored by such important authorities as Biett and Gibert, the latter of whom has specially treated on the subject of this lecture—(*Gibert, Monographie de Pemphigus*). The little boy present, who is the unfortunate sufferer from this inveterate variety of pemphigus diutinus generalis, and whose malady you have now the opportunity of minutely inspecting, is named Michael Laffy, aged ten, residing at No. 8, Price's-court, Gravel-lane. He was admitted on the 1st of September last, and is entered in the register No. 6064. He had suffered upwards of two years from his malady, for which he had unsuccessfully undergone various treatment as in and out patient at other public charities. The model of this case represents the disease as it appeared on admission. You have an opportunity of witnessing the progress made in five months. I wish I could say it was more marked, yet I think we may pronounce him better. To tell you what remedy has seemed to have had the greatest share in producing this result is beyond my power, as he has tried a considerable variety, both internal and external. Iodine in various combinations, chalybeates in vegetable bitters, sulphurous remedies, the mineral acids and opium. The external agents have been as various, stimulating lotions, and ointments containing sulphur, iodine, lead, zinc, and bismuth; and baths also of various kinds have been tried. Yet, perhaps, out of all this farrago, a mixture composed of small doses of the dilute sulphuric acid, with moderate doses of opium and a lotion containing the tris-nitrate of bismuth, have been followed by the best results; still very much has yet to be done. The slight crusts formed by this boy's disease exhibit very beautifully what I have mentioned as regards the formation of false membranes in this variety of pemphigus—as you will perceive by the microscope in the room—thus you may observe the rudiments of numerous capillaries in which the blood discs or globules are arranged like a string of small beads. I do not remember to have witnessed this appearance

in any other cutaneous crust, though I hav constantly found it in this and other cases of pemphigus diutinus, nor am I quite sure that it results from the cause I have assigned, for much patient research is still required before I can be supposed to have arrived at the required accuracy in this new field of inquiry. With respect to the third, or miliary variety of pemphigus, I have met with but few of such cases where the body has been generally affected—perhaps three or four in a practice of eighteen years, six of which have been spent in large hospitals, and I do not remember that more than one of these has occurred amongst the patients of this institution, this was in a consumptive young woman of the name of Stone, a relative to Mr Stone at the College of Surgeons. She suffered extremely from night sweats, the result of hectic fever, when, from some cause unknown, these symptoms all at once disappeared, and a fever, which I regarded as of the simple, continued type, was manifested, with the usual signs of heat of skin, loaded tongue, &c. In a day or two an eruption that I at first thought was varicella (chicken pox) appeared all over the body, but the vesicles never attained the size observed in that disease, nor did they follow the same course many disappeared in a few hours few appeared to break, and when this happened, it soon became difficult to find the spots they occupied, as they left little if any redness on the skin, and no crust or desquamation. No sooner had this eruption thus shown itself than the feverish state disappeared, and in three days there was scarcely a trace of the eruption the hectic and night sweats returned, and conducted my patient slowly along the path on which they have led so many others, till they reached "that bourne from which no traveller returns." This young woman's disease may be regarded as a case of sudomina, and, perhaps, with justice but I would not exclude the complaint designated under this variety of pemphigus a true *miliary fever I have never seen*, and, therefore, beg you will not consider that it is intended to describe it in any of the definitions I have this day attempted those parts that would seem approximating to it, portraying acute forms of the different varieties of pemphigus I would mention that a local eruption of miliary vesicles (*P. Solitarius*) is often witnessed in various acute diseases, accompanied by profuse perspirations, as before remarked in respect of *P. Simplex*, to which variety, when these vesicles attain a larger size, they become referable.

In one of the models you will observe on examination of this circumstance. The pemphigus here had arisen in a child's arm after vaccination, which occasionally happens and you will perceive miliary vesicles intermixed with bullæ and their excoriations, and a few attempts to form the imperfect encrustation characterizing this rare and curious disease.

Next week, gentlemen, our meeting shall be occupied with the disease of the skin to which the moderns have attached the name of HERPES.

ORIGINAL CONTRIBUTIONS.

REPORTS ON DISEASES OF FEMALES.

By EDWARD RIGBY, M.D.

Fellow of the Royal College of Physicians, Senior Physician to the General Lying-in Hospital, Lecturer on Midwifery at St. Bartholomew's Hospital, Examiner on Midwifery to the University of London, &c.

MALIGNANT DISEASES.

I approach this subject with some degree of unwillingness, not only from the feeling that I am able to offer but little information as regards the treatment of these terrible maladies, but because their nature and causes, and the phenomena connected with their origin, are but little known, giving rise to considerable diversity of opinion.

I believe I shall be correct in saying that there are three forms of malignant organic disease which are recognised as affecting the uterus—viz., two of a fungoid character, cephaloma, or medullary sarcoma, and hœmatoma, commonly called fungus hœmatodes; and, lastly, that peculiar deposition of hard structure terminating in destructive ulceration called cancer.

The two first resemble each other pretty closely in many respects both in the symptoms which they produce during life and the appearances they present after death they may also, when they require it, be very similar.

Cephaloma, the medullary sarcoma of Mr Abernethy—the soft cancer or brain-like tumour, as it has been called—is a soft organized vascular mass, greatly resembling brain in appearance except, perhaps, that its colour when fresh cut, is of a darker yellowish green than brain when a large section is made it presents an indistinct arrangement of numerous circular portions or divided lobules somewhat like what is seen in fibrous tumour. The brain-like portion has little or no trace of vascularity, but is of an unctuous consistence, smearing the knife which cuts it. The chief vessels belonging to the mass appear to run between the lobules to which I have just alluded, having their matrix or bed of interstitial cellular tissue. I presume that the tumour is covered with a delicate membrane (probably an extension of the mucous membrane), as is seen in fungus hœmatodes but when examined after death the disease at its surface has already passed so entirely into that state of ragged softening, which always takes place after a certain duration, as to render it no longer distinguishable, although I think it has been pretty evident, on several occasions, when seen during life, through the speculum.

Cephaloma varies considerably in its modes of appearance. Sometimes the whole uterus is pretty uniformly involved in the disease. The organ is considerably enlarged and thickened viz., to at least twice if not three times the natural size, little or no trace of the natural uterine structure being left. The pulpy ragged softening, to which I have just alluded, always commences on the internal surface of the uterus, and generally at the os which becomes quickly lost in the destructive process which is now set up, so that we might safely presume this to be the spot at which the disease usually begins. If we have the opportunity of examining before the process of softening has commenced, we shall find the os uteri much enlarged and even the cervix considerably thickened, the whole harder than usual, and after a while more or less irregular from nodular growths. If these are not yet perceptible externally, the finger seldom fails to detect them when passed through the os uteri internum the whole uterus, as felt per vaginam, is large, hard, and fixed, and examination of its cavity, whether with the finger or sound, is generally followed by a discharge of blood, although but little pain is produced at the time. If, however, the disease be of still longer standing, a ragged orifice with soft pulpy edges, leading to a cavity filled with masses of a similar character marks where the os and cervix had been.

Cephaloma occasionally assumes a polypoid form. The mass is frequently continuous with the os uteri, of which, in fact, it appears to be a prolongation, in other cases it rises by a broad base from the whole side of the uterus, tapering off into a pedicle of moderate thickness where it passes through the os uteri, and again expanding into a mass of considerable size in the vagina.

When it assumes the polypoid form it is always much more firm and hard than in other circumstances, whether this be attributable to the contact of the external air I cannot say, the growth itself appears quite insensible to the touch, and does not bleed so easily.

This disease is capable of spreading, like fungus hœmatodes, to the bladder, rectum, and adjacent viscera. From my own observations I should be inclined to say that it attacks the bladder much less frequently than fungus hœmatodes, while it spreads to the neighbouring coils of intestine more frequently. These are soon glued to the uterus and to each other by cephalomatous matter, and studded with tubercular deposits in their structure.

Although as a general rule it is by no means difficult to pronounce as to the existence of fungoid disease of the uterus, it is not always easy to distinguish cephaloma from the other malignant uterine diseases, especially in its early stage. The discharge which accompanies cephaloma usually consists of a variety of ... the menstrual ... come irregular, dark, and ... profuse or sparing, watery ... greenish watery ... at times streaked with blood, or ... shred-like portion of fibrinous matter ... it is generally fetid, and stiffens ... which has been moistened by it. Pain is not often a prominent symptom of this disease, there is pretty constant uneasiness about the pelvis, with sense of weight and bearing down, there is generally more or less hæmorrhoidal congestion present and, if the os uteri is beginning to soften and break down, pain of one or both hips. There are none of the acute agonising plunges of pain through the pelvis as seen in cancer, by degrees pain and difficulty are experienced in the evacuation of the bowels, and these necessarily increase as the disease spreads. The powers of digestion fail, so that with the constant watery discharge, and occasional attacks of hemorrhage, emaciation and debility rapidly advance, and the patient's appearance soon assumes that sallow cadaverous hue which is so well known as indicating the presence of malignant disease.

On examination we find the os and cervix uteri considerably enlarged. The transverse fissure which the os forms much elongated, the lips larger and more solid, the whole cervix more bulky and, as far as can be reached by the finger per vaginam, the uterus increased in size, solid, and more or less fixed in the pelvis. The os uteri is seldom found open in the earlier stages of the disease, although it never fails to be so as it advances, it is pervious to the sound, but will not admit the tip of the finger to pass. By degrees, however (whether this be a result of gradual softening or breaking down of its tissue or from other changes I know not), the passage becomes wider, and, if the finger be introduced some little distance, it will detect the upper portion of the canal becoming soft and pulpy. The ... state of the os uteri at an early stage of disease is mostly seen in scirrhus, where its structure is semi-cartilaginous to the feel, and there is as yet no breach of surface in the part. The sound when introduced into the uterine cavity rarely goes much beyond the ordinary extent at first, although the distance to which it passes increases somewhat afterwards, but it communicates the feeling of being in a cavity which is less moveable than that of the healthy uterus. And as the disease advances, the cavity evidently increases in size. The inner surface of the uterus bleeds readily, so that the sound is generally found besmeared with a slimy bloody fluid. That the whole uterus is increased in bulk we can readily detect by the impulse which is communicated to the sound, or to the finger applied to the os uteri, when pressure is made with the other hand above the pubes. Examination per rectum will also confirm this fact.

The inferior segment of the uterus is sometimes uneven and knobby from tubercular growths within it substance, this, however, is more frequently ... With the further progress of the disease the opening into the cavity of the uterus becomes larger, more pulpy, and irregular, the characteristic features of the os and cervix uteri are gradually disappearing and becoming obliterated, and nothing is felt but the swollen convex inferior segment with a shapeless ragged, soft-edged orifice, through which the finger generally can feel a number of nodular growths, which occasionally become detached during the examination, and, when brought away by the finger, show, beyond all doubt, the real nature of the disease.

I am sorry to confess that I can offer nothing on the treatment of cephaloma in its early stage, for at this period the patient seldom is compelled by the severity of her symptoms to consult a practitioner, and even if she does, the features of the disease are still so obscure as to afford him but little data for the discovery of its real nature. The symptoms of gastric derangement probably excite most attention, although I do not think them so marked as is often seen in cases of cancer. Neither, as far as I know, do we meet with a small isolated

solitary tubercle of cephalomatous structure in the os or cervix uteri, as is seen both in hœmatoma and cancer; but the disease seems to pervade the whole uterine tissue, the natural structure becoming gradually lost in the cephalomatous deposit. Our treatment, therefore, will chiefly consist in maintaining the general health, and combating the local symptoms as they may arise.

Whenever the system is beginning to suffer under the effects of malignant disease, whatever may be its nature, a state of the circulation is produced very similar to, if not identical with, that in chlorosis; and, as in this disease, as soon as the functions of the chylopoietic viscera have been somewhat regulated, chalybeate medicines become a most important means for supporting the powers of the system. When properly combined, they may not only be safely but also advantageously given, even under circumstances of considerable gastric derangement; and I cannot help thinking that the progress of malignant disease may be considerably retarded by the improved tone which they impart to the system. The circulation improves in strength, the flabby skin and soft muscles become firmer and more healthy to the feel, the sallow chlorotic hue gives way to a more natural tinge of colour, and the various functions of the system are performed more effectively.

The local treatment consists chiefly of emollient and sedative injections, as Decoct. Papaveris, with or without the Liquor plumbi diacetatis. In a more advanced stage I find a combined chalybeate and sedative lotion useful, which I have long been in the habit of using in every form of open malignant uterine disease; viz. eight or ten grains of sulphate of iron and extract of cicuta to the ounce of distilled water. It checks the profuseness of the discharge, renders it thicker and less watery, and allays pain.

If the disease assumes a polypoid form I think that the ligature is not only justifiable, but necessary. I am aware that such a plan of treatment is not recommended in disease of this character, but I can truly say that I have never seen any injurious result from its use in cephaloma; on the contrary, I have never seen it fail, when not used at too late a period, to produce great relief. In several cases where the health has been much broken down, and the powers of the system evidently sinking, such an improvement has followed the removal of a polypoid mass of disease by ligature, that the patient has for a time supposed herself entirely cured; the pain and discharge have ceased; the appetite, strength, and appearance have improved; and, for a while, the symptoms of the disease have nearly disappeared, so that two or more months of life, with comparative ease and health, have been obtained for the poor sufferer. No hemorrhage has occurred in these cases; the ligature makes its way through slowly, and requires to be tightened every twelve hours; the part below the ligature shrinks considerably, so as to be less than half its original bulk when it comes away, and the excessive fœtor of the discharge requires the frequent injection of warm water with chlorinated lime, &c., to keep the patient comfortable; circumstances which may easily be anticipated from the structure of the mass to be removed.

A CASE OF ENCEPHALOID TUMOUR OF THE BLADDER.

By F. A. BULLEY, Esq., F.R.C.S., Surgeon to the Royal Berkshire Hospital, Reading.

I was requested to visit Thomas Plumridge, aged thirty-eight, in the afternoon of June 5, 1845. I found him in bed, very much emaciated and suffering greatly from fever, which appeared to be of the h[illegible] kind. He had extreme thirst, a very quick and feeble pulse, and for some days previously had been troubled with a constant diarrhœa, which had weakened him considerably. His countenance was sallow and anxious. The principal pain of which he complained was in the scrotum, which was of a dark red colour, and enormously distended, with fluid diffused in the cellular membrane on both sides.

In the situation of the bladder there was a firm elastic swelling, seemingly occasioned by over-distention of the organ, and, as he had passed very little water for a day or two, I introduced a catheter, and drew off about a pint and a half of dark-coloured urine mixed with some partially dissolved coagula of blood. Having done this, I again examined the part, and observed that, although the more prominent and elastic enlargement had subsided, there remained a hard mass of diseased structure behind, which, it was evident, either involved the posterior portion of the bladder, or occupied the space between the bladder and the rectum, but it was apparently immoveable, and had a very rough and irregular surface. He did not, however, complain of any particular pain in this situation, but referred his sufferings principally to the anasarcous distention of the scrotum, which was speedily relieved by a number of small punctures being made in it with a lancet. Both legs, as well as the cellular membrane round the anus, were also in an anasarcous state. He had been so ill as to be obliged to give up his work for about six weeks, and for the last fortnight of this time had been confined to his bed; but his health had been failing for a considerable period, as latterly for a year or two, he had passed his water only in very small quantities, and almost invariably mixed with blood.

The history of the progress of his case I ascertained from his relations to be as follows:—He was originally what might be termed a tolerably strong and healthy man. About three years ago he had been employed as a labourer in a gas manufactory, and in this occupation had been subject to great vicissitudes of temperature and exposure to damp at night, and had, moreover, got into the habit of drinking largely of beer and water, of which latter it was said he took immense quantities.

He had never felt any particular pain in the situation of the bladder, but for a long time had experienced a great difficulty in passing his water, which was generally mixed with blood, and the quantity that he lost in this way at last rendered him so weak that he was no longer able to follow his work. His wife had remarked that his complexion had latterly become very sallow, and, although he had never himself complained, she thought that he gradually became thinner, and that his health had begun to fail.

For the purposes of better observation and convenience I had him removed to the hospital, where it was found necessary to introduce the catheter daily to relieve the bladder; but on the third day after his admission he died. It was observed that, during the last two or three days of life, the superficial veins of the abdomen became remarkably distended, and continued so until his death.

Inspection of the body twenty-four hours after death. On laying aside the parietes of the lower part of the abdomen and opening the urinary bladder, it was found to be partially distended with urine, containing a number of small light-coloured coagula of blood. The anterior half of the organ was apparently in a healthy state. Posteriorly a large irregularly-shaped encephaloid or medullary tumour had been formed between the peritoneum and the muscular coat of the bladder, extending from the fundus downwards, to within three fourths of an inch of the prostate gland. Owing to its greater thickness at this lower part it had encroached so much upon the rectum behind as almost to close its passage; and it is probable that the pressure of the tumour operating on the trunks of the hemorrhoidal veins had thus been the cause of the œdema round the anus, and, by its pressing upon the intestine, of the almost constant diarrhœa to which he had latterly been subject.

The anterior portion of the tumour projected into the bladder and formed a number of flat fungous growths of a darkish colour, composed of a soft brain-like substance, the same as the greater part of the mass of the tumour behind it, but much more vascular. The surface of one of these fungoid excrescences had been broken probably by the catheter, and this breach appeared to have been the source of the hemorrhage, although the whole of this vascular surface had most likely exuded blood at times.

On cutting through the tumour, three different states of the encephaloid disease were observable. At the upper portion, or that part of it on a level with and behind the fundus of the bladder, the medullary mass was in a state of softening, and easily broken down, a quantity of what appeared to be pure pus being diffused in its substance. Below this the section was precisely similar to that of a healthy brain, and in this there was no approach to softening. At its lowest part the tumour was of a firmer consistence, more fibrous, and resembling, in some degree, the texture of a scirrhous tuber, intersected by membranous septa. The termination of the ureters in the bladder was not at first discernible, the valvular arrangement having disappeared; and it was only by tracing the diminished capacity of these canals from the kidneys downwards that their openings could be discovered; below they were almost obliterated by the pressure of the mass, but above they were dilated to more than double their usual size.

On removing the left kidney from the body, it appeared to be studded over its surface with the same medullary disease, raising the investing membrane so as to give it an irregular nodulated appearance. On dividing it on its convex aspect, these nodulated elevations were found to be portions of medullary deposits which passed downwards in striated masses through the cortical and tubular portions, with healthy structure intervening; the pelvis, as well as the upper portion of the ureter, was greatly dilated; the right kidney, which was apparently in the same state as the left, was not examined.

The general structure of the liver was healthy; but in the upper part of the left lobe was a yellow elevated spot, caused by a deposit of medullary matter of medium density, of about the size of a small hen's egg, surrounded by a slight membranous cyst.

Both the lungs were equally studded with minute and exceedingly soft medullary deposits, apparently fused into the reticulated structure; but without any displacement or removal of the natural texture of the organs, such as is observed in tubercular and common cancerous deposits.

The heart was remarkably small, and its muscular structure somewhat flabby and pale-coloured; but it was closely invested by the pericardium, and there was no evidence of its being in any way diseased. In the left auricle was a large piece of light-coloured fibrine, filling about half its cavity, and extending for some distance into the openings of two of the pulmonary veins.

On cutting into that portion of it contained in the auricle, I observed in its centre a mass of what appeared to be medullary deposit in every respect similar to that found in the other parts of the body. It is probable that from the distended state of the superficial abdominal veins, and some difficulty the patient had experienced in breathing a day or two before he died, that this fibrine had been forming during that time, and that the deposition of medullary matter in its centre might have been the last effort of the system to relieve itself of the formidable disease under which it laboured, or, which is more likely, that it had become stagnated in that situation: the vis vitæ being at that time too feeble to separate it entirely from the mass of the blood, and deposit it among the morbid collections already described.

The blood remaining both in the arteries and veins of the body was of a dark treacly colour and consistence, apparently devoid of fibrine, and altogether in a very unhealthy state. On the outer side of the right leg, about its middle, was an elastic swelling, but without any discolouration of the integument covering it, which I have no doubt was caused by the same kind of disease as affected the viscera; but as time was pressing I had no opportunity of ascertaining its exact nature. There was no appearance of disease of the stomach or any part of the intestines, or of the mesenteric glands.

REMARKS.

I have related the foregoing case simply as an example of the medullary sarcoma in different stages of its development, and as affecting different parts of the body.

It will have been observed that, although the disease infested a number of organs in the body, it presented a different appearance in different situations. In one part the medullary deposit was of a firm and fibrous nature, whilst in others it presented the ordinary brainlike appearance observable in such cases. One part of the principal tumour behind the bladder had apparently either degenerated into pus, or pus had been effused into its substance through accidental inflammatory action, with which the system seemed to have sympathized, as shown by the hectic or irritative fever with which the patient was affected some time before he died.

It would be difficult to account for the different degrees of solidity which the morbid masses presented in the different parts in which they were found; but it is probable that the denser portion of the pelvic tumour had been formed first, as it was only from this portion of it that the fungoid granulations which projected into the bladder seemed to spring; and as the difficulty and pain in making water, with the discharge of bloody urine, were the earliest observable symptoms of his complaint, it is fair to infer that at that part his disease had commenced, and that the corpuscles of altered fibrine, exuded or deposited at first, were of a firmer consistence than subsequently, after his system had become debilitated by his protracted illness.

The medullary matter which had been fused into the areolar tissue of the lungs had been evidently only recently deposited, otherwise the patient must have experienced some feelings of an interruption to their healthy action while the deposit was going on. On the contrary, he had never, during his illness, been troubled with a cough, or hurried or painful breathing, or manifested any other symptom which would lead one to believe that his lungs were in any way affected; and it was only on the day before he died that any, the slightest evidence was afforded of the disease having invaded these organs; therefore, it may be assumed that these, with the other softer specimens of the deposit, had been formed at a later period of the disease.

Probably the latest effort of the constitution to separate the morbid elements from the circulating mass was exercised in the production of the deposit within the fibrous clot in the auricle, when the powers of the system were too low to allow of the disease being exuded or deposited in the larger medullary collections at a distance from the heart.

It may be a matter of doubt with some whether this central portion of the fibrous clot was really composed of the same medullary matter as formed the morbid masses in the other parts of the body; but, although I had no opportunity of examining it microscopically, I have every reason to believe, although of course I cannot speak positively, that it was a strictly analogous deposit, both from its general resemblance to the latter, and also from its entire difference in colour and appearance from the fibrine in which it was enclosed; and as there have been numerous instances recorded of medullary matter having been found in the blood, both of the arteries and veins, in cases of sarcomatous disease, it is not improbable that in this case it may have been circulating in the blood, and separated from it in this manner, during the last day or two of life.

I am unable to offer any particular opinion as to the cause of the occurrence of this formidable disease, but it is allowed on all hands that it is accompanied in its progress by symptoms of great general debility and feebleness of the circulation; it would appear, also, that through the operation of causes which influence its production in the system, or through some vital action with which we are unacquainted, the fibrine of the blood becomes altered from its natural healthy state, existing as an extraneous matter in the circulation, and that it is deposited through the natural endeavours of the system to rid itself of a noxious agent, in situations which, through injury, some peculiar irritation, or other causes, may be predisposed to receive it.

It is worthy of remark that the disease had not in any part of the body, with the exception of the bladder, assumed a hœmatoid character. Perhaps it was because the medullary matter had not been effused into any particularly vascular cellular tissue; and, although it was evident that it had been effused into the liver and the lungs, it had apparently been deposited very recently, and had not had time to erode the vessels and separate them from their natural connection in such a manner as to produce the peculiar appearances observed in this form of the disease.

I cannot better illustrate the causes of this peculiar hœmatoid condition than by quoting the remarks of an eminent writer in "The Cyclopædia of Practical Medicine" (Dr. Kerr). Speaking of fungus hœmatodes, he observes:—"That the local effect is, as in the case of other tumours, a morbid secretion, is undoubted. From its consistency it readily insinuates itself into the interstitial cellular substance, separating the vasa vasorum from their natural attachments; and, by constantly exposing the external parietes to the action of a semifluid, they may be said to undergo a kind of maceration, and hence so to degenerate as to become unequal to the retention of their contents, or readily lacerated by the slightest local injury. Thus we consider the hemorrhagic tendency to be secondary, and superadded to the secretion itself; an opinion which we conceive to be verified by the appearance of the tumour, as seen in a state of ulceration of the mamma or extremities, as modified when it occurs in the glandular structure of the testicle, or as inspected when separated from the body, and carefully washed with water."

In a remarkable case of fungus hœmatodes of the forearm, which came under my notice some years ago at the Reading Dispensary, it appeared to me that the hœmatoid character of the tumour had been produced by a constriction of the blood-vessels, which pervaded its substance, exerted upon them by the edges of the fascia under which it had originally formed, and through which it had subsequently passed in its progressive increase. The patient had undergone amputation on account of a dark-coloured fungoid tumour on the anterior part of the forearm, of about the size of a large orange, which had been removed three different times, and had as often been reproduced. After each operation the wound had apparently healed, but, within a few months, the tumour had reappeared, stretching the cicatrix, which was large, owing to the disease having been removed by incisions round the base, giving it a smooth and shining appearance, until it ultimately attained its original size. On account of its unconquerable disposition to return, it was determined, in consultation, to amputate the arm. On inspection of the amputated parts, the tumour, which was of a dark purplish colour, and covered with what appeared to be the expanded cicatrix of former operations, was found to be composed of a softish brainlike substance, with an immense number of blood-vessels traversing it in every direction, intermixed with clots of blood which had escaped from the distended and ruptured vessels. On examining the base of the tumour, it appeared to dip down into the muscular structure underneath, through an exceedingly small opening or slit in the fascia, the edges of which had assumed a somewhat rounded state, and were not apparently affected by the disease. This portion of the morbid growth, which was almost as large as a small marble, presented an entirely different structure to that of the bulk of the external tumour, with which it was evidently connected. It had none of the hœmatoid appearance, but the section of it was of a yellowish colour, and similar in all respects to the ordinary medullary sarcoma as usually described. Two or three large vessels passed through the small slit in the fascia to supply the external tumour, and, as far as I was able to judge, the constriction of these vessels by the edges of the slit had caused an accumulation in, and rupture of, the vessels within the tumour, and had thus given it the peculiar hœmatoid appearance it had assumed. Had it been possible to remove the small portion of the disease which seemed to have been the nucleus of the successive reproductions, the reappearance of the morbid growth might, at least in that part, have been prevented.

It may be a matter of interesting inquiry as to how far the exceeding smallness of the heart may have been capable of influencing the production and progress of the medullary disease in the subject of this paper. It is certain that, in the majority of such cases, the heart has been found to be preternaturally small, not as if wasted and shrunk, as it sometimes becomes in the course of a protracted illness of an ordinary kind, from an originally healthy size, but bearing the appearance either of a defective congenital organization or of an arrest having occurred to its development—a pathological condition not to be mistaken, from the pericardium in such instances being equally defectively developed, and no larger than necessary to envelop the naturally small-sized organ; whereas, in the case of a heart wasted from a normal size, as happens in chronic non-malignant diseases, the pericardium does not shrink or contract in proportion to the wasting of the heart within it; and thus a difference between the natural development of the two organs may distinguished.

If it be true, therefore, that a defective organization of the heart is pathognomic of malignant diseases, it is fair to infer that the feeble circulation resulting from this condition, at least as far as the arterial current is concerned, would favour the deposition of molecules of altered fibrine in situations disposed, from peculiar circumstances, to receive them much in the same way that a slow-running stream of water deposits more of its solid contents than one that is subject to more active motion; but it may also happen that, owing to the correspondingly small size of the auricle, there may be a retardation of the venous stream which may equally favour a deposit of morbid matter.

The treatment of long-standing cases of this fearful disease can, of course, be only of a palliative nature; but, reasoning upon the hypothesis I have advanced, I should say that, in cases where there was reason to suspect its commencing existence, or, if it were possible to form a diagnosis of its presence at its earliest invasion, it would be proper to, do everything to promote a healthy and vigorous action of the heart, by gentle and well-regulated exercise, pure air, and wholesome food, with medicines calculated to increase the general force of the circulation, on the simple principle, that while other muscles of the body, through exercise, become strengthened and enlarged, the heart might likewise become so beneficially affected as to enable it to exercise its functions in a more healthy manner, and thus render the system less liable to those diseases which appear to arise from, or are at least accompanied by, an habitually feeble circulation.

TREATMENT OF CHOLERA.

By JOHN KING, Esq., Surgeon.

Subjoined are eight cases which I have selected from many more to show the effects of the terchloride of carbon in the treatment of cholera. I head the cases by a general summary of the symptoms present and effects produced by treatment.

SUMMARY OF SYMPTOMS.

Premonitory diarrhœa and griping pains in the bowels, of varied duration, from one or two days to three weeks, the pains becoming more severe suddenly, and most frequently at midnight; vomiting and purging incessant, at first black and watery, changing to the rice-water or gruelly character. Violent cramp in stomach, back, and extremities, from the toes to hips, and fingers to shoulders—in some cases all over the body, and, as the patients expressed it, "as if drawn from limb to limb," with tingling sensation in the fingers running down the arm, the tips of fingers feeling sometimes "as if dead." The matter vomited bitter, or sour and bitter; aspect collapsed; extremities at first cold, clammy, and shrivelled; dark coloured from stagnated circulation; extreme exhaustion; some patients having got out of bed were unable to return to it; shivering, followed by heat and profuse perspiration; the warmth in extremities imperfectly restored during febrile reaction; sense of intense burning heat; great restlessness and anxiety; sinking faintness; constant and excessive thirst; tightness and oppression in præcordium and around lower part of chest; voice faint and whispering; pulse small and feeble, from 80 to

90; urine generally suppressed, from twenty-four hours to eight days; in two instances the urine was free and troublesome. In some cases no vomiting, in others no purging, but one or other present in all. The duration of disease [illegible] medical treatment commenced, from [illegible] to thirty-six; the patients complained [illegible] ness of joints and great debility after [illegible]

The terchloride of carbon was [illegible] in mixture:—

℞. Terchlor. carbon, ʒj.—ʒij.
Magnesiæ carbon. ʒij.
Mist. camphoræ, ℥vj.—℥viij.

Two or three tablespoonfuls every two to four hours, or as the recurrence of cramp requires. The following pills or powders were also given every two to four hours:—

℞. Hyd. chlor., gr. ij.
Pulv. ipecac., c gr. iv., vel. opii., gr. ¼.
Sodæ sesearb., gr. v.—x. ft. pulv.
℞. Hydr. chlor., gr. ij.
Pulv. opii, gr. ¼.
Pulv. ipecac., gr. ss.
Pulv. camphor., gr. ij.
Extr. gentian., gr. iij., in two pills.

One or two mixtures, and from six to ten powders or pills, were sufficient to allay all tendency to return of the disorder, and to establish a healthy state of the secretions of the primæ viæ.

In all the cases the warm glow in the stomach, produced by the terchloride, and the almost immediate relief from sickness and cramp, were referred to by the patients in very grateful terms, in every case within five minutes relief was obtained, and was visible in the countenance, which immediately lost its anxious expression of suffering. The mixture was given first, or with the pills.*

In these cases the tendency to febrile reaction, so marked a character of the prevailing disorders of the present season, was conspicuous, and, moderating the state of collapse, rendered the disease more amenable to medical treatment. The disease in this respect, but I believe in no other, differs from the epidemic cholera of 1832 and 1833.

CASES.

No. 1. Martha Shirley, aged 77, 10, Upper William-street. On Monday, July 27, "was suddenly affected with griping pains in the bowels, vomiting and purging; cramps of legs, feet, and hands, and generally over body; evacuations, upwards and downwards, quite black." This attack moderated without medical aid. On Wednesday, at one A.M., cramps became violent; constant vomiting and purging; evacuations like thin gruel; aspect collapsed; extremities cold, clammy, and dark-coloured from stagnated circulation; incoherency; tightness and weight in the epigastric region, and around the lower part of chest; heat and drenching perspiration followed, coldness and heat alternating; stools passed from her unconsciously in bed; urine suppressed, strength prostrated, voice faint and husky, great thirst, pulse small and very feeble. On Wednesday and Thursday the stools ran from her as she lay in bed, and were like rice-water. In the evening they became pitchy, black, and of greater consistence; on Saturday they were natural. Improvement was progressive; the cramps were relieved almost immediately by mixture, of which she took a dose, containing half a drachm of the terchloride; the system was also slightly affected by the calomel; the eight-ounce mixture was repeated once.

2. Caroline Marshall, aged 32, 11, Charles-street, washerwoman. Spare and bilious habit. For three days had griping pains of bowels. On the 28th of July, while at work in the evening, became affected with cramps in all her limbs, and generally over the body; legs and body "doubled" in consequence; pain in back and chest; breathing difficult; vomiting and purging incessant, and varied in colour, green, black, and latterly white like gruel. In this state continued till the 30th, when she was first visited. From two to five o'clock A.M., cramps were very severe, and before taking mixture, extremities retained feeble warmth; perspiration "[illegible]," alternately hot and cold. [illegible] before I saw her, [illegible] and tips of [illegible] cold and "as if dead;" [illegible] "as [illegible]" [illegible] thirst excessive, drank a [illegible] of cold water in two hours. [illegible] Wednesday to Monday following [illegible] Obtained immediate relief from mixture, of which she took two bottles. This case, as well as the former, was visited by Dr. Doyle, of the Portland-town Free Dispensary.

3. William Harrison, aged 42, carpenter, 3, Barrowhill-road. Tall spare man. On Sunday, 19th July, was seized with cramps, retching, and purging every five minutes; cramps in toes and every joint, hips, shoulders, &c., "as it pulled from limb to limb", purging at first dark and watery. Had been seen by another medical gentleman on Sunday and Monday, and took some powders and a mixture. On Monday night, when I first saw him, the dejections and vomit were like gruel; legs and hands cold, warmth alternating, cramped when cold, the least movement of limbs induced cramp; the urine suppressed for two days; pulse feeble; severe and constant thirst; great heat and sense of burning; tightness around chest, with difficulty of breathing and pain in præcordium; great exhaustion. The mixture relieved the cramps immediately, and whenever they threatened the mixture was had recourse to with the effect of quelling them and producing reaction. He took one bottle of mixture.

4. Henry Lewis, aged forty-five, 14, Charles-street, commission-agent; leuco-phlegmatic. On Saturday, July 25, felt giddy and took a blue pill. On Sunday, languid, and no appetite, pains of head and limbs; took a small basin of mutton broth. At one A.M., Monday morning, retching and purging; violent cramps of feet, legs, and inside of thighs came on; griping pains in back and bowels; violent pains across the chest and back, and difficulty of breathing; "dreadfully irritable heat of body, legs, and arms"; "feet very cold at onset"; had some brandy and hot tea, which he immediately rejected; the purging and vomiting continued incessant at first, like "congealed blood, and very black." On Tuesday morning the evacuations became like gruel, and were passed every five minutes. I saw him on Tuesday for the first time; the first dose of the mixture checked the vomiting and cramps, and on return of cramps, the mixture relieved and stopped them. The character of stools changed at six o'clock on Wednesday and became black; urine not suppressed; took about eight pills and two bottles of mixture. Seen first by Dr. Doyle, who prescribed mixture and pills.

5. Charles Amer, aged forty-two, carpenter, residing temporarily in High-street; of spare habit and fair complexion. August 5. Three weeks ago, at Sydenham, was suddenly seized with pain across the loins while at work; was unable to walk, and, therefore, carried home by his fellow-workmen; diarrhœa, with sickness and griping pains of bowels, came on and increased daily. On the above date went to bed at six o'clock P.M.; had coughed and retched all day; nothing came up till ten P.M., when rice-water evacuations took place; constant cramps of legs and chest; severe pains in epigastrium; extremities sometimes hot and then cold; congested, dark hue; pulse small, feeble; voice whispering; felt sinking and scarcely able to articulate; urine suppressed for eight or ten days; attempted to go to water-closet, and was accidentally found by his friends on the ground, being unable to return to bed; mixture speedily gave relief, and from that time began to rally; took part of two bottles of mixture and eight or nine powders. The motions continued for twenty-four hours like rice-water, but dirty-looking, then ceased. Had no stool for several days; was able to get about a little on Friday, the 7th, but very feeble in joints, &c.; continued to improve, and returned home on Saturday to Sydenham.

6. Fanny Oliver, aged about thirty, 42, Cochrane-terrace; small, delicate woman; was delivered of a girl on July 5. On the 20th of July and two following days had griping pains in bowels, and felt very faint during the while. August 1, violent purging and sickness of dark, dirty fluid, sour and bitter; severe knotty cramps in bowels, "as if all [illegible]"; very cold and shivering at first, afterwards heat and cold alternating; the matter vomited became lighter like pale toast-water, and [illegible]; tingling sensation in fingers, the hands, feet, and legs, "as if asleep"; cold, chilly state, with profuse perspiration followed; "in a tremble," very faint when heat came on; "with an insufferable sense of sinking and dreadful thirst;" continually drinking cold water; appearance collapsed; pulse small; feeble motions every ten minutes, voice very weak, scarcely able to speak. Gave powders and mixture; "received great relief from mixture"; purging ceased after second powder; had no return of cramp after third dose of mixture. After attack, great weakness of limbs and joints; soreness of stomach, limbs, and small of back from cramps.

7. Mary Green, aged twenty-two, 30, Upper William-street; dark sallow complexion; under treatment for spinal irritation. August 4, had punching of bowels for some days; seized suddenly at four A.M. during sleep with cramp of stomach and calves of legs; "legs drawn double"; vomiting and purging dark watery fluid; general coldness, with shivering, followed by heat and profuse perspiration; skin became hot, with sense of burning; taste bitter; mixture relieved greatly and "settled stomach"; everything taken previously rejected; micturated freely, and is still annoyed by it. Took one mixture and four or six pills. On examining the evacuations, which were dark-coloured and brown, a gruelly, white sediment was found at the bottom of utensils, no gruel having been taken.

8. Elizabeth Milson, aged about forty, washer-woman, 9, John-street. August 10, pinching and griping pains in bowels from eight o'clock P.M. till twelve; sickness and increasing pain; purging and vomiting dark-green fluid; "cramps from toes to hips, and from fingers to shoulders," very severe; "draws toes double"; skin of extremities shrivelled and dark-coloured; shivering, followed by excessive heat and profuse perspiration. Aug. 11, has not micturated since seizure; pulse suppressed, very feeble, 88; feels sick when cramp comes on, but is relieved by mixture in less than five minutes; much thirst; tingling sensation in fingers and down arms; tongue brownish, furred; giddiness and buzzing sound in head. Aug. 12, very weak; passed a quiet night; cramps ceased; griping once this morning; stools watery, brown, throwing down a white gruelly sediment; pulse weak, 60; tingling continues; feels very sore in legs, hips, and from shoulders to fingers; expresses her satisfaction at relief derived from mixture; has had two bottles of mixture and ten pills; not all taken; convalescent.

10, Portland-terrace, Regent's-park,
August 12, 1846.

* The tingling sensations mentioned preceded the use of the mixture. They are said also to be an effect of the terchloride.—Vide *Medical Times*, Dec. 9, 1843.

HOSPITAL REPORTS.

MEDICAL TIMES PRIZE REPORTS.

SECOND SERIES.

Reported by THOMAS FRANCIS PANSON, Esq., of St. George's Hospital

SURGICAL CASES.

CASE OF STRANGULATED FEMORAL HERNIA.

Hy. Phillips, aged nineteen, servant, of a spare habit of body, was admitted January 14, at 3, p.m., with a swelling in the right groin, which he said appeared the night before after a fit of coughing; he did not take much notice of it at first, as he said he had frequently had a lump come in the same situation after making any unusual exertion. But this time the appearance of the tumour was soon followed by pain at the part, and a dragging pain in the abdomen, with eructations and vomiting, first of the contents of the stomach, but latterly of stercoraceous matter. The tumour was circumscribed, resonant, about four inches round its base; its upper edge slightly overlapped Poupart's ligament, it was on the level with, and external to, the spine of the

pubes, and the spermatic cord was situated above it. It received an impulse on coughing, appearing to dilate and expand to the touch, and it did not disappear when the patient was in the horizontal posture. His bowels have not been opened for two days previously, and he is now labouring under a good deal of febrile excitement; the abdomen is tympanitic, but not tender on pressure.

He was placed in a warm bath for half an hour, when a considerable degree of faintness having been produced, the taxis was employed, at the same time bending the hip, and carrying the knee over the opposite thigh; gentle pressure was made downwards, and slightly backwards, but it failed in causing the swelling to disappear.

As it was now nearly twenty-four hours since its appearance, Mr. H. C. Johnson made an incision from the upper to the lower part of the swelling, dividing the integuments and superficial fascia, with a few superficial vessels; then the fascia propria, or sheath of the femoral vessels, and the cribriform fascia, when a very thin peritoneal sac was exposed; a portion of this was pinched up with forceps, divided with a knife, and a director being introduced, the opening was enlarged upwards and downwards little. A clear fluid escaped, and a portion of the small intestine, which appeared only slighly discoloured, was brought to view. The intestine was now held aside, and a director cautiously introduced to the edge of Gimbernat's ligament, with its grove turned inwards. Considerable difficulty was experienced at this part of the operation, owing to the tightness of the stricture. Sir A. Cooper's bistoury, which has only a limited cutting edge, was next passed along the groove of the director, and part of the fibres of Gimbernat's ligament were divided, slight pressure was then made on the intestine to empty it of its contents (fecal matter and air), and it was gently and gradually returned. The integuments were then brought together, and the patient was placed in bed.

9, p.m. He has had no more vomiting, and has no pain in the abdomen; pulse 100, hard.

Calomel, gr. vj., statim.; H. sennæ, ℥iss., magnes. sulph. ʒss., 6tis horis.

15th. Skin moist; pulse 94; but his bowels have not been open, and his tongue is rather furred.

Enema decoct. avenæ, Ol. ricini, ℥j., statim.

6. p.m. Bowels have not yet been open.

Cal. gr. vj., statim. Ol ricini ʒss., post horas duas.

16th. Bowels have been opened several times during the night, since which he has slept well. Tongue moist; skin cool; pulse quiet.

17th. Tongue clean; bowels open; no pain in abdomen, and the hand being pressed on it causes no pain. The wound appears to be healing by adhesion.

18th. Bowels open; tongue moist; no thirst; pulse 90, quiet; but there appears a slight redness, and puffiness round the wound, in consequence of which the adhesions were broken down and a little healthy pus escaped.

20th. Redness and puffiness have disappeared from the wound, there is a free healthy discharge from it; there is no tenderness around, nor any in the abdomen; but the patient has a red tongue and his bowels are constipated.

Haust. rhei., ℥iss statim.

22nd. Bowels open; tongue clean; a healthy discharge from wound, and no tenderness about it.

Beef-tea one pint.

27th. Wound granulating; bowels regular; pulse natural; appetite good; no thirst.

Beef-tea two pints. Mutton chop.

Feb. 3. A truss applied to-day.

5. Left the hospital.

Femoral hernia implies an escape of some of the contents of the abdomen through that part of the femoral ring, through which the absorbent vessels pass; this part being bounded externally by the septum of fascia dividing it from the femoral vein, internally by Gimbernat's ligament, anteriorly by Poupart's ligament, posteriorly by the os pubis. It is much more frequent in women than in men, both because the space between the femoral arch and the border of the pelvis is larger in them, and also because the structures which pass through it are smaller. But it may also happen in men, especially those of weak fibre, as in this instance.

The hernia having entered the femoral ring passes on through the tubular sheath formed anteriorly by the fascia transversalis, posteriorly by the fascia iliaca, and emerges through the saphenous opening of the fascia lata, turning up over its falciform process. It thus has for its coverings skin, superficial fascia, fascia propria, cribriform fascia and its peritoneal sac. The epigastric artery passes upward and inwards about half an inch from the external side of the neck of the sack. When the obturator artery is given off from this vessel, it also generally passes outside the neck of the sac, and in the female would be situated the round ligament, in the male the spermatic cord immediately above it.

The sac of a femoral hernia is seldom or never so large as that of an inguinal, but the portion of gut protruded is exceedingly tightly constricted, especially by the sharp, thin edge of Gimbernat's ligament, and hence strangulation is very apt to occur.

The symptoms of strangulation in this case soon began to shew themselves; they were first some pain at the part, with a severe dragging pain at the umbilicus, flatulent eructations; vomiting of the contents of the stomach, afterwards that of the intestines above the stricture. Sometimes a person may have stools, and yet all the symptoms of strangulation be present, but the stools which are voided are only the contents of the bowels below the stricture. The abdomen was distended from accumulation of flatus.

The not now been relieved, after a time the abdomen would have become more tense and tender; there would have been great anxiety, a pale countenance, hiccough, a wiry, rapid pulse, the pain would perhaps have ceased, and the patient have expressed himself as somewhat better; the tumour would then have decreased and become emphysematous, giving a diagnostic mark of the occurrence of gangrene, and death would soon have followed. Perhaps the abatement of pain and decrease of the tumour might have led an inexperienced surgeon to hope that the gut had been returned; but they are almost sure signs of the gangrenous mischief within.

The situation of the tumour immediately distinguished it from bubonocele, for Poupart's ligament was above its neck, and the spine of the pubes internally and on the same level with it, whereas, in bubonocele, Poupart's ligament is below, and also the spine of the pubes. In crural hernia, also, the abdominal ring is open, which is not the case in bubonocele.

Of course, the suddenness of the symptoms and the elastic feel of the tumour, at once distinguished it from enlarged gland, glands also are loose, if one should suppurate, there would be the want of impulse in coughing, which would be present in hernia. Had it been varix of the femoral vein, it would have disappeared on the horizontal posture being assumed, and would have reappeared on pressure being made at Poupart's ligament, which would have effectually prevented a femoral hernia from descending. Had it been psoas abscess there would have been fluctuation, and it might have disappeared in the horizontal position, and it would have come on gradually, or have been preceded by pain in the back and loins.

In the *treatment* all our endeavours must be to return the intestine into the abdomen, for there is no safety for the patient till then, therefore, the great rule by which we should be guided is, to waste as little time as possible in trying the effect of remedies which are uncertain in their operation; for it is a disease in which, if we do not get forward, we are almost sure to go backward; and when we consider that a single hour may be fatal to the patient, and that the operation, abstractedly considered, is very seldom fatal, the rule which is adopted at St. George's, viz., to operate directly one or two of the most likely remedies to succeed, have failed, appears to be one most likely to be attended with success. In fact, sometimes so many attempts to reduce the gut have been made before the patient arrives, that the operation is frequently proceeded with at once. The most efficient remedies are the taxis, with the warm bath, bleeding, and perhaps cold to the part. Sometimes clysters of tobacco, or its fumes, introduced into the rectum have been tried, but they are generally only a waste of time. The taxis, with the warm bath, had failed with this patient, and he was not a person to stand under bleeding; indeed we had had one proof of the inefficacy of faintness in the warm bath. In performing the taxis force must never be employed, but gentle and gradual pressure, with a kneading action of the fingers; force can never do good, and may do an immense deal of harm to the inflamed intestine; indeed, the intestine has been ruptured by the employment of too much force. Sometimes the taxis is inapplicable from the extreme sensitiveness of the patient.

On opening the sac a little clear fluid escaped, which was merely a little serous exhalation from the peritoneum, increased in quantity by inflammation.

Gimbernat's ligament is the preferable place to divide the stricture, for if we cut upwards the spermatic cord would be injured (in females the round ligament need not deter us), and if we cut upwards and outwards we should wound the epigastric artery. The bowel did not appear to have suffered much from the stricture; the part against Gimbernat's ligament was especially examined, as that is the most unyielding and sharpest part of the stricture. The intestine might have been dark coloured from impeded circulation; this differs from mortification, which arises from congestion and stagnation, and is of a dull ash, or slate colour, it is also soft, and the serous membrane easily peels off. If it be merely discoloured it may be returned, for when the stricture is removed, the local disturbance will cease. But if it be mortified it must not be returned, for the gas and fæces would escape into the peritoneal cavity, and would quickly cause a fatal result; but we must here make a free incision to procure the evacuation of the loaded canal above, and leave the wound open; nature will generally cast off the slouhs, and the wally of the gut will be approximated by adhesion, and continuity established generally without our aid; but a very rigorous diet must be preserved for a long time, that is, a diet which will nourish without causing distension of the bowels.

The great thing to guard against after the operation is peritonitis, which must be prevented if possible by procuring free evacuations from the bowels, giving saline medicines and a spare diet. Our patient required rather active treatment to procure evacuations; but he had not a single symptom of peritonitis.

The edges of the wound appear to have suppurated, and it was the confinement of matter which gave rise to the redness and puffiness about the wound, so, when a free exit was allowed, it soon disappeared. We must not set down the slight suppuration which occurred as suppuration of the hernial sac, for that is attended with the most violent symptoms, very much resembling, in fact, those of strangulation.

REVIEWS.

A Practical Manual of the Characters of the Blood and Secretions of the Human Body, &c. By J. W. Griffith, M.D. London: 1846.

A book, something like the one before us, is very much wanted in the present day. Discovery is all the rage; and whilst discoverers themselves are too much occupied in chasing new pursuits, to look after "game already won," we ought to be obliged in all earnest to their humble followers, who are satisfied with chronicling events and putting them in a tangible shape before us. In this light we look upon the Manual of Dr. Griffith. It aims at nothing novel, and in such

wise has some claims to our regard, for we are fond of unpretendingness.

The subject embraced by this monograph is one of great amplitude and consequence. It contains many vexed questions, both of ancient and modern date, and is not easily to be compressed by chemistry and pathology as at present extant. In good truth there is what we may call, in homely criticism, a vast deal of scientific nonsense, in all the learned nomenclature about nothing which antagonist chemists, microscopists, and physiologists are now a days making. We have seen many revolutions in these sciences, or rather amongst their votaries in our time. Not to go into years long gone by, whose memory, on the good old principle of "de mortuis nil nisi bonum," ought, of course, to be held sacred. We have plenty of proof in recent days of discovery. A pseudo chemist has started up with a wonderful notion of turning one element into another—a freak somewhat analogous to that of legitimately "setting the Thames on fire," and strangely enough he has found dupes willing to sanction him, until a little rigid questioning and repetition of his processes has proved the soi-disant discoverer to be nothing better than a scientific black-leg. Microscopists we know are continually at war with one another about things visible and invisible, and now and then seem in a fair way to realize the fable of the Kilkenny cats, by worrying in mutual earnest until there is nothing left to fight with. Physiologists are proverbially at daggers drawn about precedent, priority, and such like; there is so much of the sauve qui peut, or "deil tak the hindmost," as is far from palatable to such as are not lovers of literary pugnacity.

It is for these things that caution and reserve are indispensable for the right reception of novel scientific announcements. Something like proof should accompany discovery ere it be implicitly believed. At the same time, when new facts are put before us with anything like an air of probability or proof, they ought instantly to be made current capital of those who make it their business to gather and distribute knowledge. In this respect the author of the book before us is not quite up to the mark. Many of its contents do the compiler much credit for industry, and judgment in selection, but many others are far in the rear of modern discovery. The article on pus, and the means of its detection in the blood is very incomplete; and in distinguishing between pus globules and colourless blood corpuscules, he forgets to mention their relative shapes. The chemical characteristics of lymph he takes from Gmelin. We are surprised that Dr. Griffith should have overlooked the more recent and accurate analyses of this fluid. The discourse on saliva and ptyaline is very old fashioned, and, according to the late investigations of chemists, altogether incorrect. In treating of fæces, Dr. Bird's observations on the green ones of children are quite overlooked. We could point to many other similar faults, which, like these, are quite inexcusable in a work professing to recapitulate the latest discoveries in chemistry and microscopy. No doubt the author has had very good intentions at heart in the compilation of his volume, and in some respects these intentions are answered. We hope, on next meeting with him, to find that he is less in the rear of advancing scientific knowledge.

A Series of Essays on Inflammation and its Varieties. By HENRY CLUTTERBUCK, M.D. 8vo. Lond., 1846. Pp. 67.

The announcement of a work on inflammation from the pen of a physician like Dr. Clutterbuck, already well known for his original and sound pathological and practical views on this subject, will be hailed with every satisfaction by the generality of the profession. The discoveries which have been made in certain of the auxiliary branches of medicine since Dr. Clutterbuck last enlightened its members by his learned discourse on fever will give him further scope at the present time for the exposition of the comprehensive and obscure subject of inflammation. Ourselves rejoice most cordially at the appearance of the essay before us, the first of a series that will be required to complete the subject. To enter into an analysis of these as they appear singly, would be neither to do the justice to the theme nor to the writer that they severally merit. In commending, therefore, the unceasing [illegible] of the author, we must withhold minute notice of his work until it shall have been completed, when we will gladly enter into its critical consideration from beginning to end.

TO CORRESPONDENTS.

A Student *is perfectly right on the necessity of abolishing flogging in the army. It cannot be done too soon. It must be as affecting to the surgeons in attendance as cruel to the individual punished. But, between the colonel administrators of a system and the evils of the system itself, a wide distinction should be drawn.*

Marius, *who insists that a good medical directory would be quite as serviceable as a registration bill, and be much less of a job, should have written more legibly; we cannot decipher half the note.*

The advertisement "Friday Pulpy" is not fitted for our columns.

A Subscriber *can only get a correct answer from Messrs. Sherwood, Paternoster-row, the publishers of the work inquired after.*

Legalis *insists that the warrant for White's flogging being granted[illegible] was illegal and that consequently, the jury, in believing Wilson's evidence, should have had Colonel Whyte and Dr. Warren committed for murder.*

W. S. *is [illegible] concerning the medical directory advertised. We do not know the parties or their intentions. A directory for the country is much needed. The pledge given under false misrepresentation is [illegible], and should not be [illegible].*

M. D.—*We have neither time nor inclination to notice the Satirist's official defence of Mr. Erasmus Wilson.*

A. S., *we are assured, will find his capabilities [illegible] with on an early day.*

Mr. Hooper's *complaint of "Coroner's" injustice to medical witnesses is, unfortunately, now so common[illegible] a character that we might give up all our space to similar records. "Inquest reform" is becoming an urgent necessity of the day.*

A Subscriber *inquiring about baths will do well to consult our advertising pages.*

W. B.—*The examination questions were given correctly. Our correspondent will see that, although comprised in two days, there were four distinct examinations on four separate subjects.*

Mr. Alcock *should write to Messrs. Tyler and Co., Warwick lane, Paternoster row.*

Mr. Adill's *communication has been received.*

Mr. Hooper, *surgeon, of Brunswick street, Hackney-road, writes as follows:—"Observing a paragraph in your last [illegible] excellent journal of the 8th, [illegible] during the existence of Asiatic cholera in this metropolis, I beg respectfully to put you in possession of the fact, that four cases of that truly terrible disease have fallen lately under my care at [illegible], with the presence of every symptom I observed in that disorder in India, together with similar rapidity of course and fatality, [illegible] sufficient to constitute identity.* * * * * *My view [illegible] no so much to attract attention to the cases themselves as to bring a few facts relating to this immediate neighbourhood before the eyes of the proper authorities. I refer to the total want of drainage in Brunswick-street, and the continuation of it called Haggerstone—the consequently offensive and dangerous collections of stagnant water and filth, which render these spots the fruitful source of the most grave disorders. You would scarcely believe, without seeing it, that immediately in front of the large church, called St. Mary's, Haggerstone, to which a throng of respectable persons resort, there is a filthy pool from which emanate the foulest miasms, the pathway, totally neglected by the parish authorities, is frequently covered with water in bad weather. This pool, or gutter, extends nearly the whole length of the street, now a bustling thoroughfare, and would be a disgrace to the meanest country village. The garden of the house in which my last case occurred (all of them being in this line of street) is, from want of an outlet, overflowing with dirty water and the contents of a cesspool; such also is the case in most of the houses in this crowded locality, and here innumerable cases of bilious diarrhœa and dysentery have been, and are, constantly occurring."*

THE MEDICAL TIMES.

SATURDAY, AUGUST 22, 1846.

Perhaps after all, there is no better friend to Conservatism than your outrageous Radical Snob. When a man preaches to you that all noblemen are tyrants, that all clergymen are hypocrites and liars, that all capitalists are scoundrels banded together in an infamous conspiracy to deprive the people of their rights, he creates a wholesome revulsion of feeling in favour of the abused parties, and a sense of fair play leads the generous heart to take a side with the object of unjust oppression.

For instance, although I hate military flogging, as the most brutal and odious relic we have left of the wicked and torturing old times, and have a private opinion that soldiers of crack dragoon regiments are not of necessity the very wisest of human creatures; yet when I see QUACKLEY the coroner giving himself sham airs of patriotism, and attacking the men for the crime of the system—(of which system I are as much guilty as COLONEL WHYTE, unless we ill [illegible])—I find myself led over to the brow-beaten side, and inclined to take arms against QUACKLEY. Yesterday a fellow was bawling by my window on account of the trial at Hounslow, and "the hinfamous tyranny of british hofficers, and sawidge kurnel, hall to be ad for the small charge of won apny." *It is that fellow, a Radical patriot thank you, or a Radical snob, and which is it that he want to put down flogging or to get money?*—Punch (article, Snobs of England), Aug. 8.

THE "crowner's 'quest law" at Hounslow opens questions of deep and permanent concern to the whole medical profession. The outrages it presents on the rights and privileges of medical witnesses, gross as they are, appear before the public in so authorized a shape, coming from a *medical* coroner, that, unless strongly denounced and repudiated, they will serve as precedents of as wide application as they are of fearful injustice.

Let us just look at Dr. Warren's treatment. From the very commencement of the inquest he was an accused man. If there were any grounds for the coroner's investigation *he* had improperly allowed White to be over-flogged, or had ill attended him afterwards. Even to moot the inquiry was to bring *his* professional character under suspicion. To do him this severity, where was the pretence? The man had died weeks after the flogging: the minutes of a post-mortem examination, conducted by two other surgeons, were before the coroner, and gave conclusive evidence of a sufficient cause of death. Why, then, should the injurious presumption be wantonly raised that Dr. Warren, though his practice was supported by the autopsies, and might be by the deliberate testimony on oath, of two other surgeons, had been guilty of some possible enormity of professional conduct? If every coroner thus dealt with medical attendants, we should have but a succession of inquests on the judiciousness of their practice. Thus, then, instead of holding every man innocent until proved guilty, this medical coroner adopts as his maxim the holding of every medical man guilty until proved innocent. But the wrong does not end here. Before letting Dr. Warren go unaccused and unsuspected even on the sworn testimony of two unimpeachable medical

witnesses, he determines to try what two other medical witnesses may say. Accordingly Messrs. Day and M'Kinlay, by his own appointment, examine the body; but, odd to say, they prove the needlessness of the implied imputation, for they join with the other two surgeons in their opinions, and unite in acquitting Dr. Warren!

Dr. Warren is thus not only proved not guilty—he is not only actually proved innocent by two surgeons, who publish the grounds of their convictions—but "Coroner Quackley's" own two surgeons reiterate the examination, and also prove his innocence. Yet mark the result. Though thus triumphantly done justice to, the *medical* coroner is not satisfied that a worthy medical brother has not committed crime, and selects his own servant and close friend to give him an inculpation if it be possible. The inculpation *is* given; and on the convenient evidence of that one person—four witnesses to one against him—the coroner does his best to secure a brother doctor's conviction by the jury and public, of brutal and murderous neglect of a human being confided to his professional care!

What then, as thus evidenced, is the principle of action of this medical coroner with medical men? Just this. When the charge is horrible brutality by a professional brother possessing a character of unimpeached rectitude and humanity, "Coroner Quackley" will sooner believe one man inculpating than four proving innocence! Nay, when innocence is established by four testimonies, he will go on with the investigation on the mere chance of picking up, among his own acquaintance if necessary, a witness who, whatever his evidence, starts with the disadvantage of having four to one against his accuracy!

This curious piece of "crowner's 'quest law," which will not acquit on four testimonies, but will convict on *one*, suggests one query *en passant*. If Dr. Warren's word alone was not enough—if the testimony of Drs. Reid and Hall was not enough added to it—if, in further addition to that, it was not enough when the testimony of Messrs. Day and M'Kinlay was joined—how happens it that the medical coroner no sooner gets the testimony of Mr. Wilson on the other side—isolated, unsupported, and directly contradicted—than he declares it to suffice of itself? Five medical men consecutively coming to one opinion, and opposed by no single evidence, are not to be believed without further investigation; but one man, even opposed to five, is quite satisfactory: nothing further is asked or required! Character, liberty, life, may depend on a jury's acceptance of this isolated and contradicted opinion: it was criminatory to the highest extent; it was opposed to four disinterested opinions perfectly exculpatory; yet the medical coroner, adopting it himself and exerting himself to get it adopted, did nothing to see whether any other medical men could, would, or should support it!

An act of this kind prepares us for some extraordinary things under the head of its *accessaries*:—

1. The self-sufficing witness has to examine the exhumed body twelve days dead; and, that he may be embarrassed by no awkward questions, or still more awkward proofs, as to what he did see in the decomposed subject, the *accused* doctor is strictly prohibited from being present, or having any person on his part present. Having an odd position to sustain, a droll case to prove, and a hard battle to fight—so many medical witnesses against him—it was *probably necessary* that Mr. Wilson should be *aided*, if not by any other witness's testimony, with the useful but rather anomalous privilege of registering the evidence given, or supposed to be given, by the dead body, under the observation of no criticising eye. It left the accused at his mercy. Nothing could be fairer.

2. The jury have it carefully concealed from them that the anti-doctor witness is an ex-servant and useful private friend of the coroner. The magistrate maintains with him the most distant courtesy; and extracts from his diffident modesty the whole *rigmarole* of his certificates, diplomas, and books, as if it were news of some just-discovered continent. If one medical witness accusing a medical man *was* to be believed in preference to four witnesses exculpating him, it would, of course, not do to tell the jury that the four witnesses were independent men, and the one witness the coroner's hanger-on; or that, as a medical witness could aid a medical coroner in getting up an electoral sensation, a medical coroner could help a medical witness in turn to get his name before the public. The more real and the less avowed connection between the two, of course, the better; and, against such fearful odds of evidence, it was at least politic to eke out the lion's skin with that of the fox.

3. Mr. Wilson, having drawn up a report of the third autopsy in concurrence with the disappointing Mr. Day—a medical man actually selected by the coroner, and the only other one present—discovering that the unpliable Mr. Day did not go with him—found it convenient, therefore, to drop the joint statement, and to give in evidence a written report, subsequently concocted, which Mr. Day never saw before, and which, when he did see, he indignantly repudiated! Standing alone in the accusation of a medical brother against four opposing testimonies, Mr. Wilson had a difficult position, and was, of course, not to be restricted by a *medical* coroner to ordinary weapons.

4. Mr. Wilson's evidence, as we showed last week, was not only false in scientific fact, but incoherent and absurd in every aspect—one monstrous figment of the brain based on another, till we had a very Babel of anatomical nonsense and gibberish. For a medical coroner to have told the jury that, unsupported and alone, this kind of science did not form the strongest possible ground for believing that a virtual manslaughter had been committed by a medical brother, would have been very hard on Mr. Wilson, and might have prevented his "discoveries" bearing the bell over the sober realities of his four opposing brethren.

5. Dr. Hall, in making his statement in conflict with Mr. Wilson's, is so rudely and frequently interrupted by the coroner that he is obliged to break off in the middle. One against four was entitled to a small advantage of this kind. How else could he hold ground?

Finally. "The medical men were ordered to leave the room, and each was called in separately"—Mr. Wilson, of course, having the ear of the jury last. It was desirable to this medical coroner that the public should see that medical men could not be trusted for an honest opinion in the most solemn case if they were not, like the lower kind of Newgate witnesses, examined in the absence of each other. *O Rare Medical Coroner!*

With such facts before us, is it to be wondered at that Mr. Fox Maule declares officially that the investigation cannot be left where it is, or that medical men from all parts of the country should be addressing us in such language as the following?—

"CORONER'S TORTURE.

"Sir,—In my last letter I emphatically protested against coroners employing their own surgeons at inquests, especially in cases where the coroner and surgeon are associated together in writing in the same journal and enforcing the same political views.

"The coroner's court is held by all true Englishmen as one of the most important safeguards which the people possess. No person can meet with violent death without inquiry; and in any case where doubt exists in the minds of the relations of a deceased person there is no difficulty in obtaining a thorough investigation.

"He, then, that would violate the rights of the coroner's court is an enemy to the people, and a destroyer of the rights and best defences of the subject.

"Such is the general feeling upon this point, that there is hardly an instance upon record where the powers of the coroner have been abused, or where the noble privileges of the court have been prostituted to selfish, political, or party purposes.

"However, a case has lately occurred where a coroner with known political bias has presided over an inquest, and has given strong reason for believing that he did not inquire into the cause of death, but procured a verdict preconceived and predetermined before one tittle of evidence had been adduced. In this inquest the coroner began his mock inquiry, but, to his chagrin, the evidence of one skilful surgeon after another was directly contrary to his intended verdict, and would have upset the political movement that he had in prospective. Upon this he obtains the evidence of his man Wilson, and he takes his statement in preference to that of other distinguished members of the medical profession.

"It is clear that here inquiry ended and dictation began—that here the right of the coroner's court was violated, and that it was prostituted to enforce his own peculiar views.

"The cunning means used to assist him in his course also show the nature of this foul affair; for his continual and extended adjournments caused much public excitement, which subsequently he has taken advantage of to afford him a subject to talk in Parliament, and delude the old ladies of Exeter-hall.

"Whatever may be the opinion of flogging—whatever may be thought of the end attained—there can be no question that no one can justify a perversion of the objects of the coroner's court for any purpose whatever; and, if it has been perverted, the delinquent should be at once called to account for his transgression.

"The object attained by the means employed was to hold to the public scorn of weak-minded people some of our most gallant officers and our distinguished medical authorities. In this way the coroner has acted as a tyrant, and inflicted his illegal torture upon honest and virtuous men.

"Against this tyranny, and against this torture, I enter my solemn protest; and I call upon the public to protect themselves from a repetition of

the freaks of this demagogue, and preserve inviolate the rights of the coroner's court.

I am, your obedient servant.

A Constant Reader.

STATE OF THE PUBLIC HEALTH IN THE SPRING QUARTER, 1846.

The last report of the Registrar-General shows a considerable increase, for two or three months past, of disease and death. In the spring quarter, ending June 30th, 43,582 deaths were registered; being greater, numerically, by 2,853 than those in the corresponding quarter of 1845, and by 4,731 than those in the same quarter of 1844. During the spring quarters of the eight years preceding the present, there has been an obvious diminution in the rate of mortality, especially in from 1841 to 1845; in the quarter last past, however, there has been a striking reverse.

It would seem that circumstances perfectly controllable and capable of amendment have been mainly instrumental in promoting the ravages in question. "Within the last three months," says the Registrar, "*ten thousand* lives have been destroyed in a part only of England by causes which there is every reason to believe may be removed." Certain places in Lancashire and Yorkshire appear to have been the chief sufferers. Liverpool, Sheffield, and other towns in the north, have been visited by epidemics of almost unequalled fatality; and the diseases, proportionately to the population, were fully one third more numerous than in London.

The great increase of mortality in the past quarter has been chiefly owing to the prevalence of zymotic diseases—those of the sporadic class have scarcely been more numerous or fatal than usual. Diarrhœa and dysentery have been for the most part in the ascendant, and have made havoc without mercy. In some places their ravages have been excessively severe. Generally speaking, simple vomiting and purging have been the leading symptoms. The vomited matter has usually had a bilious tinge, occasionally or constantly—sometimes yellow, and more rarely green. In some cases, a distressing retching has continued long after the contents of the stomach have been expelled, at last running into severe spasm, and producing excessive pain and anxiety; in other cases, a troublesome nausea, without vomiting, has lasted for days. The evacuations, *per anum*, have mostly been frothy, and of a light yellow, like barm. In some instances they have been dark green, or black, from depravity of bile; and, again, almost colourless from the want of it. Ourselves have known the dejections to be of the rice-water kind of genuine cholera, without, at the same time, having any reason to suspect the ailment to be other than common bowel complaint. The amount and frequency of the purging have occasionally been excessive. In several cases that have come under our care, the patients, for hours together, have scarcely been able to leave the night-chair without being obliged directly to return to it. A natural consequence of this abdominal pain, tending downwards, and constrained position, has been tenesmus of the severest kind, piles, and hemorrhage *per anum*. Cramps and spasms of terrible intensity have been the occasional concomitants of this gastro-intestinal irritation. We have seen the convulsive spasms of the extremities, and fixed contraction of the abdominal muscles, equally severe of late with the like symptoms in cases of pure cholera. At the time this fatal disease prevailed in this country, it was an idle notion with many of the profession that cramps and spasms were peculiarly pathognomonic of it; forgetful that these are very common indications of intestinal irritation, however originating, and that the direst forms of cholera are unaccompanied by muscular pains of any kind.

The probable causes of the epidemic in question are several. There are some people who, however well advised, can never profit by instruction. They are always at contraries with nature, and doing it voluntary outrage whenever they can. These are chiefly such as can put no restraint upon their appetites, and are little particular about the materials that indulge them. It can be no wonder, then, when the weather is excessively hot, and the oxygenation of the blood by respiration correspondently slow, that substances, gross and indigestible, should offend people's stomachs; give their livers extra work, and disorder them into the bargain; and put the whole system in a state of commotion. Cucumbers, cold salad, peas, young potatoes, pickled salmon, ices, and gourmands best know what besides, are the gastronomical perquisites of this season of the year; and it can be no wonder that their inordinate indulgence is followed by some bodily penalty or other. Very many cases of bowel complaint, as it has lately prevailed amongst us, have been owing to the indiscriminate and redundant use of food. In our own experience, some of the severest cases of the ailment have been due to gluttony. Substantial beef and mutton, and stale bread, and such like things, people are not generally in the habit of taking to excess; when these are eaten, the appetite usually stops short of mischief. The case, however, is different with the edible items above specified. People seem to think that they must be eaten extravagantly, or not at all. Hence, the rule of their ingestion is the converse of what it ought to be—they are swallowed with a generous *gusto*, until the last mouthful pauses in its progress, which is considered the only genuine *sine quâ non* to a cessation of mandible hostilities. The reverse of indulgence like this is the decency that should be observed, at least in tropical weather.

Another cause of the epidemic in question is the intolerable heat we had some time past. It was next to impossible that a scorching temperature like that could be endured with impunity. There was comparatively little ailment at the period of its prevalence: but, as is usually the case in climates naturally temperate, its cessation is the opportunity for the advent of its *sequelæ*, in the form of visceral congestion and derangement, in very threatening states.

A third cause, and perhaps the most influential of the zymotic diseases of the season, is impure air. To breathe a free, healthy atmosphere, is a cardinal point in the maintenance of health and strength. To lack this advantage, is to encourage the accession, and favour the progress, of disease. That this is the fact, the statistics of mortality abundantly prove. Where there is imperfect ventilation, as especially is the case in crowded and confined districts, together with inefficient drainage and sewerage, it must necessarily happen that the neighbouring inhabitants become unhealthy. This will be particularly the case in hot, humid weather. Not only is the constitution less able, under such circumstances, to resist the influence of noxious effluvia, but these, being emitted in unusual abundance, taint the atmosphere proportionately, and in the same ratio predispose to, or actually excite, disease. This fearful but unheeded truth has lately added to its many previous manifestations. The Registrar says:—"In the metropolis, the deaths at the close of June from diarrhœa, dysentery, and common cholera, rose to forty weekly, and have since increased. Nor is it to be wondered at. Notwithstanding the improvements effected when cholera was last epidemic, the foul untrapped sewers, and the ground areas of the best streets, emit noisome smells and volatile poisons, which are as fatal as arsenic to a certain number of persons. London is surrounded, too, by stagnant putrid ditches, as some cities are by walls. It would be well not to wait carelessly until cholera reaches the country; but to look before, remove these nuisances, and purify the reeking atmosphere which gives to the disease breath, life, and being." In another part he says, "The inadequate supplies of water by companies, the imperfect sewerage in towns, the open drains and ditches, and the general neglect of cleanliness, leave everywhere great quantities of organic matter to decay and putrify in the midst of crowded populations. In such circumstances the mortality, like putrefaction, is always increased when the temperature is high, and epidemics of diarrhœa, dysentery, and cholera prevail."

We trust that the time is near when judicious, practical, benevolent observations like these will fasten themselves upon the minds of the community, and dispose their hearts to duly regard, and their persons duly to enjoy, the beneficial effects of fresh air and cleanliness. With various local authorities, no doubt, much fault rests for not providing against accumulation of filth, stagnation of waters, and so on; and we trust shortly to see some wise enactment which will comprehend a right estimate of the physical condition of the people, and the means best calculated for protecting and providing for it. At the same time much rests with the people themselves—soap is not very costly, and water can generally be had for nothing: and yet the majority of the poor will not be at the trouble of keeping themselves clean. All we can do is to tell them the dangerous consequences of filthiness, and leave it to their personal discretion to provide for their personal safety.

Hooping-cough, we perceive, has been very prevalent during the past quarter. Not only

have the cases been unusually numerous, but fatal also, as the returns testify.

In several districts there has been remarked the great disproportion of deaths in infants under a year old. This is imputed, and we fear too correctly, to the baneful use of Godfrey's cordial and other narcotics, which are administered to the little victims to send them to sleep and save the trouble of nursing.

Smallpox, of course, has taken its due place in the list of "ills that flesh is heir to." And so may it be expected to do until the prejudices of the people are turned away from vaccination. It is really a mystery that the accumulated evidence of years has not yet sufficed to dispel the foolish infatuation of the mass concerning the loathsome disease and its antidote. We find, on looking over the returns, that in some places smallpox has been extensively fatal; and, as usual, the great majority of the sufferers have been unvaccinated. If ignorant, deluded people will persist in refusing a remedy so innocent and efficacious, it is fitting that, for the safety of the public in general, Government should authorize certain means for the enforcement of the sanatory rule of vaccination.

THE NEW REGISTRATION BILL.

This plagiarism on Sir James Graham's bill offers as good a specimen of legislative audacity as it has ever been our fortune to witness.

There is not one clause in it not pillaged.

There is not one clause in it that has not been vulgarly vituperated by the very man that now adopts it.

Thus unscrupulously got up, it is not less unscrupulously laid before the public.

There never was a bill so surreptitiously introduced into Parliament, or so surreptitiously tried to get passed through it.

It has never been submitted to the opinion of the profession, and at this period of the session *cannot* have the consideration it requires.

There is, finally, not in Parliament a man in whose hands the profession would less soon see a bill that concerns their interests.

The profession should immediately set their face against this extraordinary piece of legislative dishonesty.

If the bill be good it should have been introduced with professional sanction, and have been duly placed before Parliament in fitting season.

If the bill be bad, as the hands it has fallen to suggest, the surreptitious mode of smuggling it through Parliament implies, and as all crude attempts to do great things by halves must be, the stronger we oppose it the better.

Not a moment is to be lost in petitioning Parliament against the daring plagiarism.

ROYAL COLLEGE OF CHEMISTRY.

Some very curious disclosures are expected to take place at the general meeting of subscribers to this institution, to be held on Monday, the 31st of August. It appears that Dr. Gardner, the Secretary, has procured his name to be inserted as lessee of the premises, used as the college, without the knowledge or sanction of the committee; and that a disclosure of this fact, with other circumstances, having led to his suspension as secretary, he has made the bold though unsuccessful attempt of holding the premises, *vi et armis*, against the admission of the committee. Some odd scenes of door-breaking have already taken place; but, from the zealous and determined manner in which the committee have taken their post, there is no doubt as to the result of the squabble itself, and little apprehension entertained of its permanently interfering with the interests of this valuable institution.

DR. BOSTOCK, F.R.S.

Among the deaths recorded in our last week's obituary will be found that of Dr. John Bostock, F.R.S., &c., whose name has been long and prominently associated with the progress of medical and general science. He was a native of Liverpool, and the only child of Dr. Bostock, who, after a bright but brief career of practice in that town, was cut off at an early age in 1774. The subject of the present notice was born in 1773. Under the immediate tuition of Dr. Priestly, Dr. Black, Dr. Monro, and Dr. Hope, he became imbued with an enthusiastic love of science, more especially as connected with physiology and the practice of medicine.

Having graduated at Edinburgh in 1794, he settled in his native town, and there became distinguished by a successful practice, and an active encouragement of the local charities and literary institutions. He removed to London in 1817, when he finally renounced the practice of physic, influenced by the greater facilities afforded by the metropolis for the pursuit of his favourite study and the enjoyment of the society of his scientific friends. To those already mentioned he was now able to add the illustrious names of Day, Wollaston, and Young. Prior to this period he had contributed many important articles to "Brewster's Encyclopædia," and to most of the leading literary and scientific journals. He now proceeded to publish his "Elementary System of Physiology," a work of the greatest interest and importance, and the first connected view of the subject that had been put forward in this country, the third and last edition of which was published in 1836. He afterwards wrote a History of Medicine, which forms part of the introduction to the "Cyclopædia of Practical Medicine." His other writings are most numerous. But it is not possible in a brief memoir to enumerate even the titles of all his separate publications, or of those contributed by him to the cyclopædias and journals of London and Edinburgh.

Since his residence in London he has been associated with most of the scientific societies, and has taken an active share in the management of many of them. He was president of the Geological Society in 1826, vice-president of the Royal Society in 1832, and has been several times on the councils of the Linnean, Zoological, Horticultural, and Medico-Chirurgical Societies, and of the Royal Society of Literature. He may be said to have held a prominent position among those who, in our day, united their energies in the advancement of medical and physical science.

In private life no man was more respected or beloved. He was equally ready to impart the overflowings of his sensitive and affectionate heart, and the varied stores of knowledge with which his intelligent mind abounded.

Honours to the Profession in France.—Surgeon-major Dr. Maher, agrégé of the faculty of Strasburg, formerly professor at the hospital of instruction of that town, and at present chief surgeon to the military hospital of the Saltpetrière at Algiers, has just been appointed Knight of the Legion of Honour by the French Minister of Public Instruction.

MISCELLANEOUS CORRESPONDENCE.

THE "NATIONAL INSTITUTE" OF ENGLAND AND "THE MEDICAL CLUB OF FRANCE."

[To the Editor of the Medical Times.]

Sir,—All those who have convinced themselves that the cause of the general practitioners of this country is in their own hands, and that a firm union is the only means by which they can render it triumphant, must rejoice at the prosperous commencement which has been made in the foundation of a voluntary National Institute. The excellent spirit in which the design has been conceived, carried on, and received, can leave no doubt as to ultimate, and not distant, success. Of course the numbers who have joined it (although quite as great as the most sanguine could have expected, when we consider the difficulty there always is in setting any institution on foot which calls for repeated payments, and the disappointments which have attended so many other ill-contrived and worse-executed attempts), and the funds at the disposal of this body, are at present too limited to admit of much being done as yet; and the object of this note is to suggest to the managers what I think very desirable as a commencement.

The position of the medical reformers of France and of our own country is just now singularly alike. Last year, as your readers are aware, a large congress met in Paris to discuss their grievances and to devise suitable remedies. I have perused all the speeches which were delivered on that occasion, as well as numerous other documents relating to the subject, and I quite agree with a writer in the "Medico-Chirurgical Review" of January, that the practical evils which the medical profession labours under in France are much greater than those which afflict it in our own country. I have only to do, however, with the attempt made for remedying them. Just as in our own country, the Government at first showed itself disposed to afford the requisite redress, and declared its intention of proposing or sanctioning a legislative measure forthwith. Business of a more exciting and, to legislators, of a more profitable character was, however, allowed to engross all the session; and this, together with the opposition offered by the constituted medical bodies interested in preventing the desired changes, has determined the postponing of the introduction of any measure ***sine die.***

The profession in both countries, being thus thrown upon its own resources, has resolved upon a similar course in either, viz., the maintenance of a firm union as a basis for future operations. The leading men in the French movement have determined to this end, among other means, upon the establishment at Paris of a "Medical Club of France for the protection of the interests of science, the dignity of our art, and especially for rendering closer the ties of medical co-fraternity." Rooms are to be taken and maintained by an annual subscription of 20 francs; and to these members are to have free access from morning to midnight, under such regulations as may be devised by an elective council.

This seems to me an admirable mode for bringing practitioners more together, and thus acquainting them with their true interests, and removing that feeling of jealousy and ill-will which only exists in consequence of such non-intercommunication. For the purpose of enabling their members thus to associate with each other on terms of entire equality, I would then suggest, that the first operation of the committee of management of the Institute should be the hiring a large room or rooms in a central part of London, and the furnishing it with the medical periodicals and other appliances of the like kind. Opened during the day and the evening, it would form a place of agreeable and useful resort, it would form, also, a convenient hall for the holding meetings, which should be very frequent, whether for business, the advancement of medical science, or the purposes of recreation; and on the premises all the executive business of the council and secretary might be transacted. Whether any portion of the other advantages usually understood to be afforded by clubs, as regards eating and

drinking, might be realised, is doubtful; but, at all events, those of the useful and inexpensive character I have alluded to are at once attainable; and I feel certain that, were such a place of resort or "home" for the practitioner to be opened, great numbers would at once avail themselves of them.

Seeing that the Institute intends demanding the same subscription from country as from town members, it might seem unjust to devote the funds to objects which will be chiefly beneficial to the latter. I believe, however, that this will be found a means of adding very materially to the funds of the Institution, and yet very little augmenting its expenses. Moreover, less than a guinea subscription could not well be asked; and our country brethren are much better able to pay this than we poor fellows of the metropolis, upon whom, nevertheless, nearly all the work of the Institute must necessarily fall. Thanks, also, to the railways, we shall see our country brethren much more frequently in town than heretofore; and the advantages which such an establishment is likely to confer upon even the casual visitor are worth his consideration.

The council of the new Institute will have a difficult task to perform, and suggestions will flow in upon them from all quarters. I quite appreciate the desirableness of the numerous important objects which have already been stated as being those the Institute should contemplate. But we must not attempt too much or too many things until our position is more assured, and our exchequer more flourishing; but, as a measure preliminary to others more important, I venture to think the establishment I have alluded to is worthy the attention of those who have the management of matters in their hands. J.

INFLUENCE OF SPIRITUOUS DRINKS ON CUTANEOUS DISEASES.

[To the Editor of the Medical Times.]

RESPECTED FRIEND,—Permit me, through the valuable pages of the Times, to express my obligation to James Startin, Esq., for supplying the cases in support of his views of the relation that subsists between the disease, acne, and abstinence from alcoholic drinks.

These cases, indeed, do "speak for themselves," and to me their language is somewhat fearful. But I cannot admit that they prove any of the three propositions with which we set out, viz. 1st, That cases of acne had multiplied since the introduction of teetotalism. 2d, That this increase is attributable to the practice of total abstinence from alcoholic drinks. 3d, That disorder of the digestive system is a common consequence of such abstinence.

The cases do not prove an increase in the frequency of the complaint, because we have no other numbers with which to compare them. Is it not possible that the London Cutaneous Institution and J. Startin's own celebrity may have, of late years, drawn together a greater number of cases than had previously been presented to his notice in a given time, without actual increase in the community at large? But, admitting this increase to be a fact, the cases reported afford no proof of total abstinence from alcohol being the predisposing cause, as we are not furnished with evidence to show that the patients, during the period of their abstinence from alcohol, were properly fed, and that their general habits were conducive to health. For the same reasons, the cases afford no proof that disorder of the digestive system is a consequence of abstinence, whether sudden or gradual. Besides this, I see no reason in these cases to attribute recovery, in a single instance, to the use of alcoholic beverage. What! did hot-air baths, sulphur fumigations, chalybeates, mineral acids, vegetable bitters, iodine, and mild nutritious diet contribute nothing towards correcting and energising the digestive functions, increasing the cutaneous circulation, and determining blood to the surface? Or, could they not entirely fulfil these indications without the adjuvancy of that most vulgar and apparently most seductive tipple, gin and water?

The idea of assisting an ill-used, jaded stomach by administering gin and water reminds me of a woman in Edinburgh who was seen attempting to give some gruel to a weakly baby. The child did not seem to like it, and would not take it. "Ah," said the mother, "*you know what you want*," and, reaching down a bottle, poured fully half a wine-glassful of whisky into the child's food. The effect was stated to be extraordinary. As soon as the child was sensible of the presence of the stimulus it gobbled up the food with astonishing eagerness. Yes, the poor little stomach was "apt to neglect its office," and its mother, like many higher authorities, entertained exalted notions of the efficacy of alcoholic stimulation. She would begin, no doubt, prudently, with less than half a wineglassful, and the effect encouraged her to proceed, properly proportioning the dose according to the increasing infirmities and growing alcoholic appetite of the child. I can perceive no difference between this instance and those before us, but in the greater grossness of the infantine case. The principle is the same. Yet what would be thought of its being brought forward as an illustration of the text "take a little wine for thy stomach's sake!" That alcoholic liquors, both fermented and distilled, may be sometimes useful in the treatment of disease, I entertain no doubt. I believe that almost every substance possessing active principles may be used medicinally. My objection is to their routine employment, where equally good results could be secured by less objectionable means; and to the encouragement of an idea that alcohol, as a beverage, is one of the necessaries of life.

I am, very respectfully,
JOHN FOTHERGILL.

Darlington, 8th Month, 11th, 1846.

N.B.—My last letter was, by mistake, dated 2d Month, instead of 7th Month, 28th.

CALUMNIES ON THE WESTMINSTER HOSPITAL LECTURERS.

[To the Editor of the Medical Times.]

SIR,—A paragraph appeared in the *Lancet* of last week, stating that the annual distribution of prizes had been withheld at this school. On behalf of the lecturers and myself, I desire most emphatically to deny the truth of this statement; and we beg of you to publish our contradiction of the false assertion. The following books and instruments were awarded as prizes—Andral's Clinical Medicine; Watson's Lectures; Fresinius' Qualitative Analysis; Bell on the Nerves; Burnett's Botany; Hooker's British Flora; A Case of Obstetrical Instruments, &c.; Geological and Mineralogical Case for Blowpipe Analysis; together with an extra prize given by Dr. F. Bird and myself to the second candidate in botany. These prizes were distributed among the following gentlemen—Mr. Collins, Mr. Mullins, Mr. Tapson, Mr. Wales, Mr. Price. In two classes the answers of candidates were not deemed by the examiners of sufficient merit to deserve a prize.

The lecturers would not have considered it necessary to make this statement public, but that a series of articles have from time to time appeared in the *Lancet*, based on false information communicated to the editor, not intended to correct or criticise any real neglect or abuse in the school, but mainly calculated to bring into discredit those who possess the confidence and esteem of the students. By this contradiction we leave the profession to judge the motives and appreciate the animus of these unsubstantiated and malicious statements.

I have the honour to be, Sir,
Your obedient servant,
W. R. BASHAM,
Physician to the Hospital, and Hon. Sec. to the School.

Westminster Hospital, Aug. 18, 1846.

MEDICAL SCHOOLS OF THE UNITED STATES.—From the catalogue of these institutions which we have received, it appears that, during the past year, the number of students has been nearly 5,000, and that the degree of M.D. has been conferred upon 1,300.—*American Journal of Medical Sciences.*

UNIVERSITY OF LONDON.

M.B.—FIRST EXAMINATION.—EXAMINATION FOR HONOURS.—1846.

Thursday, August 13.—Morning, 10 to 1.

ANATOMY AND PHYSIOLOGY.—EXAMINERS, MR. KIERNAN AND PROFESSOR SHARPEY.—1. The head being divided by a vertical section in the median plane, and the dissection being commenced from the inside of the pharynx and fauces, and carried outwards to the integuments, you are required to describe in their order the parts that would be successively met with in so dissecting a space marked out as follows:—Above, by the zygoma, the body of the sphenoid and basilar process of the occipital bone—below, by the base of the inferior maxilla and great cornu of the os hyoides—behind, by the meatus auditorius, the mastoid process and the upper part of the sterno-mastoid and anterior vertebral muscles; and before, by the anterior border of the masseter and the tuberosity of the superior maxillary bone, so as to include the pterygo-maxillary fissure and posterior palatine canal.

Afternoon, 3 to 6.

1. Describe the parts situated in the plantar region of the foot (except the bones) in the order in which they present themselves on dissection.

2. Give an account of the several structures which enter into the formation of the skin, including a description of the glands, hairs, and nails.

Friday, August 14.—Morning, 10 to 1.

CHEMISTRY.—EXAMINER, PROF. BRANDE.—1. Explain and illustrate the methods of determining the specific gravities of solids, liquids, gases, and vapours.

2. Explain the construction and action of the common voltaic battery; the respective influence of the size and number of the plates; the circumstances which render its action inconstant, and the arrangements by which this inconstancy is prevented: state the causes which influence the direction of the electric current, and the changes which the different electrolytes suffer when the circuit is closed. Describe the theories of the electrolytic decomposition of aqueous solutions of sulphate of copper, and of nitrate of potassa.

3. Describe the external and the chemical characters of the varieties of urinary calculi; the composition and properties of their proximate components; and explain the chemical principles upon which the medical treatment of calculous disorders is founded.

4. What are the principal metallic substances constituting the granular ore of platinum? How are they respectively separated, and what are their characteristic properties?

Afternoon, 3 to 6.

MATERIA MEDICA AND PHARMACEUTICAL CHEMISTRY.—EXAMINER, DR. PEREIRA.—1. How would you proceed to determine the purity of nitrate of silver, with especial reference to the suspected presence of the nitrates of potash, soda, lead, and copper?

2. Describe the different methods employed in commerce for making sal-ammoniac, and the mode of preparing *Hydrargyri Ammonio-chloridum*, Ph. Lond.; and explain the changes which occur during these processes, according to both the ammonium and amidogen hypotheses.

3. Give a botanical description of the fruits of *Alpinia Cardamomum, Momordica Elaterium*, and *Daucus Carota.*

4. Describe the musk-bag; stating its situation in the musk animal, its structure, and the supposed uses of its contents. State the class and order of the musk animal. Point out the characters by which genuine musk-pods are distinguished from spurious ones. Describe the chemical characters of pure grain musk, and the conclusions which have been drawn with respect to the nature of its odorous principle.

5. Describe the medicinal properties, uses, and doses of Assafœtida, Chloride of Barium, Colchicum, and Uva Ursi.

6. You are required to name,—
   α. The barks respectively labelled A, B, C, D, and E.
   β. The leaves and fruits marked F.
   γ. The fæcula labelled G.

[The use of a microscope will be supplied to those candidates who desire to avail themselves of its aid in answering this question.]

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

EXAMINATIONS FOR THE FELLOWSHIP.

August 4.

ANATOMY AND PHYSIOLOGY.—1. Describe the femur, and mention particularly its processes, the form of its articular surfaces, and the parts with which they are connected, the muscles inserted into it and arising from it, and the situations of these origins and insertions.

2. Describe the knee-joint.

3. Describe the mode of opening the abdomen in an examination after death; mention the regions into which the cavity is divided, and describe the situation of the viscera in those regions.

4. Describe the course of the common carotid artery, its relative position, and the parts covering it externally—the point of its bifurcation; the course and relative position of the external and internal carotid arteries and the branches of the former.

5. Describe the stomach; specifying its form, position, and component structures, also its blood-vessels and nerves.

6. Describe the urinary bladder of the male; its form, position, connection, and component tunics: also the male urethra, its course, dimensions, lining membrane, the parts surrounding it, and the openings into it.

August 6.

SURGERY AND PATHOLOGY.—1. What is the usual result of an incised or lacerated wound of the scalp, the cranium being at the same time denuded, so far as the bone is concerned? Is death of the bone a necessary consequence? and, if not, what treatment should be adopted, in order to prevent such death?

2. In what situations may ecchymosis occur from injuries of the head? May such ecchymosis be confounded with any other injury? and what is the proper treatment?

3. What are the various kinds of fracture of the skull, and in what situations are such injuries most dangerous? What are the symptoms and treatment of such cases?

4. What is the nature of concussion of the brain? What are the primary and what are the secondary symptoms? what injurious consequences of a more or less permanent character may ensue? and what treatment ought to be adopted under the several states of such injuries?

5. The seat of hydrocele and its various kinds; the symptoms and diagnosis of the complaint. Describe the palliative and the radical cure.

6. The symptoms of retention of urine from stricture; the modes of relieving the patients, either by the use of instruments or other means; the operation necessary when the natural course of the urine cannot be restored.

N.B. No junior candidates were examined on this occasion.

BRISTOL SUMMER ASSIZES.

August 17, 1846.

THE MASTER, WARDENS, AND SOCIETY OF APOTHECARIES OF THE CITY OF LONDON V. FRANK BARGEER WALL.

[*Before Mr. Justice Erle and a Special Jury.*]

Mr. Cockburn and Mr. Barstow appeared for the plaintiffs, and Mr. Stone for the defendant.

Mr. Barstow having opened the pleadings,

Mr. Cockburn proceeded to address the court and jury as follows:—May it please your Lordship, Gentlemen of the Jury, — This is an action brought by the Master, Wardens, and Society of Apothecaries, under an act of the 55th of George III., chapter 194, which makes it penal for any person to practise within this realm as an apothecary without having undergone an examination and obtained a certificate of qualification from the Society of Apothecaries. Gentlemen, this is a charge of very considerable importance with reference to the life and health of the subjects of this country. You can easily understand that, if an unlimited license were allowed to all persons, whether qualified or not, to practise as medical men, the consequences might be most fatal to the safety of her Majesty's subjects, and in this, as indeed in every other civilised country, a system, under some shape or modification, of medical police and regulation has been thought necessary for the protection of the public. Accordingly this act of Parliament was passed, establishing, or rather new-modelling and giving new powers to, the Society of Apothecaries, and intrusting them with the execution of this act, and the performance of the important duties which attach to them under its provisions. (The learned counsel having read the sections of the act which appoint a Court of Examiners and render it penal for any person to practise as an apothecary who has not undergone an examination and obtained a certificate of qualification, continued: — The act, therefore, makes these important provisions, that no person shall practise as an apothecary except he has undergone an examination and received a certificate from the Court of Examiners appointed by the Apothecaries' Society, and that if he does he shall forfeit a penalty of twenty pounds and the mode in which that penalty is to be recovered is by action at the suit of the Apothecaries' Society. They are the persons to whom the Legislature has by this act of Parliament intrusted the superintendence of the medical department which falls under the definition of the apothecary, and it is part of their duty to see its enactments enforced and carried out: it becomes, therefore, a part of their bounden duty, if they discover any person practising as an apothecary who has not received the certificate required by this act of Parliament and it is a sacred duty, because the safety of the public is involved in its discharge; it is a sacred duty which they have to perform to the public and the Legislature, which has intrusted them with these powers, to enforce the provisions of the act, and to insist on the penalties which it imposes if persons choose to infringe upon its provisions. This is not, therefore, the case of a common suit at the instance of an informer. The Society of Apothecaries have no private interests to serve, no private motives to gratify; they have simply a public duty to discharge, and it is in the discharge of that public duty that they have instituted the present proceedings. Now, gentlemen, the defendant in this case has, as I shall be enabled to show you, in various instances infringed the provisions of this act of Parliament: he has practised as an apothecary in the cases which my learned friend has brought under your notice in opening to you the pleadings in this case; he is here practising in this town, and to all intents and purposes carrying on his business, as if he had been examined and received his certificate from the Apothecaries' Society. Gentlemen, he has not done so; he has never submitted himself to the examination the act requires, and he is in possession of no certificate which justifies him in practising. These circumstances having been brought under the notice of the society, they have felt they had but one simple, straightforward course of duty to fulfil, namely, that of instituting these proceedings. I am not instructed to say a word against this gentleman's competency; he may be qualified, or he may not, I know nothing on the subject. If he be qualified, he has nothing to do but to submit himself to the examination, which, if he has the necessary qualification from education, he may readily undergo: and, if he has not that qualification, he certainly ought to be prohibited from practising, and he cannot in any way complain that these proceedings have been instituted against him. Gentlemen, I am therefore instructed to bring this case before you. I believe I shall have no difficulty whatever in substantiating the fact against the defendant with reference to all the instances I have mentioned. I do not know whether any difficulty will be attempted to be raised on the subject of what constitutes the practice of an apothecary: I am provided here with numerous authorities to show that the class of cases this gentleman has affected to treat, not being surgical cases but medical cases—diseases of the brain, the lungs, the heart, the stomach, and so on—fall within the province of the apothecary. There is not the slightest doubt, from the decision of the judges and the authority of the courts, that all these classes of cases come within the proper definition of practising as an apothecary; and anybody who practises in that capacity without a certificate renders himself amenable to a penalty.

Mr. Stone here interposed, and said: I take for granted you do not seek to recover more than one penalty in this case?

Mr. Cockburn: I do not know. What is it you propose to say?

Mr. Stone: That we cannot resist this action; and that the Apothecaries' Society have done nothing more than their duty in instituting these proceedings. Unfortunately this gentleman was not aware of the law which rendered it necessary for him to take out his certificate. He is a gentleman highly competent to practise; he has been practising as a physician in America; he served a regular apprenticeship in this city; he came back in November, 1844, and he certainly has been practising as an apothecary since that, at the times you have stated. I take it for granted the only object the Apothecaries' Society can have is to compel him to submit himself to the ordinary examination and to take out his certificate.

Mr. Cockburn: Certainly.

Mr. Stone: All I can say is, that he is a gentleman of high medical and surgical attainments. He has erred in mistake as to the law.

Mr. Cockburn: Let the gentleman be all my friend describes, that is the more abundant reason why he should conform to the law; if my friend says he does not wish to resist this action, I am satisfied to take one penalty, with this condition, that, as there are the costs on the other issues, it should be upon payment of the general costs of the action.

Mr. Stone: Of course.

The Jury, under the direction of the learned Judge, then returned a verdict for all the penalties in the declaration, amounting to £160, on the understanding that execution should issue only for one penalty and the general costs of the action.

GOSSIP OF THE WEEK.

STATE OF MEDICINE IN OCEANA.—We find in the *Revue Orientale* some interesting details on the state of medicine in the islands of Gambier (Archipelago of Mangareva, Oceana). These details were communicated by Dr. A. P. Lesson, physician-in-chief of the French forces in Oceana.

The Mangarevians have no medical men, properly so called, among them—every person acting as such and prescribing simples, or employing the prayers of the priests to their idols. In the Marquesas, and some others of the Oceanian archipelagos, the warriors are drawn from a separate class, who attribute to themselves the exclusive right of performing medical functions. At Mangareva it is not so: still, however, among the recent popular remedies here is one which is praised as a specific for dysentery, a very common and very fatal disease in the Gambier Islands, and which may be attributed to the abuse of the recent sugar-cane. The remedy consists in the bitter and astringent juice of a plant. They use, in the treatment of syphilis, the sudorific properties of a plant which appears to belong to the order Cyperaceæ. The itch, which they call *paka*, is by no means uncommon among them. Wounds (*maki*), pustules on the face, elephantiasis of the legs, cataract, opacities of the cornea, and squamous lepra, are the other affections to which they are most commonly

liable. The commonest of all, however, and the most fatal, is pneumonia. The missionaries have accordingly begun their cares by instructing the natives how to build cabins, having noticed that dwellings exposed to the winds are a frequent cause of the disease.

The women in these islands are delivered with a facility unknown among civilised nations. As soon as labour pains commence—wherever they are attacked, whether at the foot of a tree or on the seashore—the wives are delivered by the efforts of nature alone; in very rare cases is recourse necessary to assistance from the husband or the friends. In difficult cases a few women and even some men, enjoying a special reputation gained by experience, are called to effect the delivery; scarcely is the woman delivered than she goes to bathe in cold water, and resumes the usual course of her domestic duties. Nevertheless, the natives have traditions of some very difficult labours which lasted during several days. Serious disorders, ending in death, occasionally follow this dangerous practice of bathing in cold water. In general, however, the young mothers who bathe immediately after their delivery recover very well; by the third day the milk-fever has ceased, and the secretion of that fluid is performed with regularity. The women do not employ any plant either to increase the secretion of milk or to suppress it. Their (in this case) happy ignorance has no recourse to a host of useless means for this purpose.

The mothers suckle their children during about twelve months; a few have recourse to nurses for this purpose, but whether this is a privilege of the nobles, or whether all mothers who find themselves unable to suckle their infants have recourse to it, seems uncertain. The practice is a privilege of the royal family, without doubt.

The tenderness of the women of Mangareva towards their infants is very great; they are, therefore, excellent mothers in every acceptation of the term; still, however, there is no rule without an exception. One of the missionaries relates an instance of a mother wishing to bury her twin children alive; he was enabled to save them. These twins are at present seven years old. The husbands manifest considerable repugnance for their wives during menstruation and the period of gestation; on this head they seem to possess the laws of Moses in all their rigour.

A cemetery has recently been established in the Gambier Islands, after the European fashion; and the old custom of exposing the dead has been abolished.

Royal College of Surgeons.—Gentlemen admitted members on Friday, August 14, 1846, viz.:—Messrs. S. Gower, E. Whittle, T. Daniell, G. F. H. Brown, J. S. Nedham, H. Helsham, J. N. Tompson, S. Griffith, J. R. Humphreys.

Apothecaries' Hall.—The following gentlemen were admitted licentiates on the 13th of August, 1846:—Daniel Edward Hamilton, George Cheesman, Henry Winterbottom, Fred. Fawssett.

On Sunday morning last one of the wards in the Hotel Dieu of Paris was suddenly undermined. One of the patients getting out of bed felt the ground tremble, and gave the alarm just in time for the patients to escape without injury.

Surgical science at Lyons has recently received a severe loss by the almost simultaneous deaths of the two brothers Martin, senior surgeons to the Hôpital de la Ch... of that town. One died at the age of seventy-nine years, the other at the age of seventy-five.

Embalming Plants.—A Swedish botanist asserts that he has discovered a method of embalming plants. He has imparted his discovery to the Academy of Stockholm, and has sent there a rose-tea plant which he embalmed by this process in 1844, and which is still in a perfect state of preservation.

It is stated that the number of cases of insanity which have occurred lately has frightfully increased. At this time at the Saltpetrière all the female patients who had previously been calm have become furious.

The *Gazette* of Augsburg states that the typhus fever which raged during the month of July at St. Petersburg carried off at least 900 patients daily.

Cultivation of Rice.—There has been recently made in the environs of Arles an experiment in vegetable chemistry of the greatest interest. The cultivation of rice has been tried on the lands salted by the mouths of the Rhone, and has perfectly succeeded. This eminently productive culture has, besides, the advantage of taking the salt entirely from the soil, which is an alluvial soil of the first quality, so as to render it suitable for all natural productions. This year 300 hectares have been converted into rice grounds, an example which will doubtless be promptly followed.

Dr. Thibert.—On several occasions lately we have had to direct the attention of our readers to the collection of artificial preparations in pathology made by Dr. Thibert, and exhibited within the last year in London and Paris. We regret to announce the decease of the ingenious inventor, who had only reached his thirty-sixth year. Health, youth, and fortune had been sacrificed by Dr. Thibert to the perfecting of these models, and it appears that his life was brought to a close at the very time when there was some prospect of his reaping a reward for his scientific labours.

On the fifth instant, during the violent storm which broke over the town of Verdun and its neighbourhood, the lightning simultaneously struck a farmer and his wife. They both died instantly.

New Sign of Death.—M. Repault has lately directed the attention of the Academy of Sciences to a new sign of death. It is *perfect flaccidity of the iris* when the globe of the eye is compressed in two opposite directions. If the individual be living, the pupil retains its circular form, notwithstanding the compression. If he be dead, the aperture becomes angular, and the circular form is lost.

MM. Rambaud, surgeon-in-chief to the military hospital of Bonn, and Gasté, physician-in-chief to the African army, died in Algeria during the last month.

A strange epidemic has just broken out in the valley of the Isere. The disease commences with fever, pain in the loins, and pains in the head and chest, followed by vomiting; and it attacks the inhabitants very suddenly. It is chiefly prevalent in country districts.

The Medical Society of Paris have lately proposed, as a prize subject, the influence of the iodide of potassium in the treatment of syphilitic diseases. The last prize, consisting of a gold medal valued at 500 francs, was awarded to Dr. Payan, of Aix.

Sulphuric Acid in Colica Pictonum.—At Turin, where lead colic is very common, Dr. Bertini has during several years been in the habit of treating it with great success by means of the sulphuric lemonade.

Surrey Benevolent Medical Society.—The half-yearly meeting of this society was held on the 10th of August, at Box-hill, near Dorking, under the presidency of Mr. Martin, of Reigate. The society was instituted in 1812. It is supported by an annual subscription of £2 from each member, payable for twenty-five years only. The society at present possesses a funded property of £4,000, and affords relief to several widows and children of deceased members.

Dr. A. B. Garrod has been appointed physician to the Royal General Dispensary, Aldersgate-street.

Thread from Pine Leaves.—The leaves of the pine-tree, which is very common in Germany and France, but especially in Prussian Silesia, have hitherto been rarely used, except as food for sheep. M. Weiss, the proprietor of a forest at Zuckmantil, in Silesia, has discovered a cheap system of maceration, by means of which he obtains from these leaves a kind of thread and tow which leave nothing to be desired. The Baron Humboldt has reported on this subject very favourably; and the King of Prussia ordered, some time since, a hundred beds, of which the mattresses and the coverings were made of pine thread, for the military hospital at Berlin. It has answered perfectly, the resinous odour arising from it entirely driving off all insects. An establishment, to which M. Humboldt has lent his name, is now being built at Brœbnitz, near Breslaw, to carry out this useful invention.

The Potato Failure.—The accounts from Clare, in the south, and Armagh and Fermanagh, in the north, all speak of the rapid spread of the pestilence. In Armagh, it is stated, one half, at least, of the crop is already destroyed, and of the remainder the stalks are showing symptoms of decay, while the potatoes attached to them are no larger than walnuts. A gentleman of great practical experience in agricultural matters states that on his journey to Dublin he did not see three fields free from the prevailing pestilence, the stalks everywhere presenting a sooty rotten appearance. He is also of opinion that the wheat and oat crops will be below an average, at least in the midland districts, where they are not only thin, but extremely backward, considering the late period of the season. It appears that the potato can never again in Ireland be relied on as an exclusive source of food for the poor.

Mr. Pittard, the gentleman whose suspension we noticed a fortnight since in an editorial article of this journal, has, we understand, been reinstated in his office.

A searching investigation has just been commenced into the quality of the articles supplied as food to the patients in the Parisian hospitals. The investigation was excited in consequence of the delivery, at several of these institutions, of milk which was unfit for use.

Dr. Taylor has resigned the office of physician to the University College Hospital. Several gentlemen are candidates for the appointment.

We wish particularly to call the attention of pathologists, and of the governors of institutions possessing museums, to an advertisement of the sale of Dr. Thibert's collection of anatomical and pathological models in relief. These models have been highly praised by the scientific men of all nations.

MORTALITY TABLE.

For the Week ending Saturday, August 15, 1846.

Causes of Death.	Total.	Average of - years.	
All Causes	967	808	968
Specified Causes	958	802	961
Zymotic (or Epidemic, Endemic, and Contagious) Diseases	288	201	188
Sporadic Diseases.			
Dropsy, Cancer, and other Diseases of uncertain or variable Seat	98	99	104
Diseases of the Brain, Spinal Marrow, Nerves, and Senses	144	155	157
Diseases of the Lungs, and of the other Organs of Respiration	186	227	204
Diseases of the Heart and Blood-vessels	24	23	27
Diseases of the Stomach, Liver, and other organs of Digestion	115	87	72
Diseases of the Kidneys, &c.	7	6	7
Childbirth, Diseases of the Uterus, &c.	9	9	10
Rheumatism, Diseases of the Bones, Joints, &c.	10	6	7
Diseases of the Skin, Cellular Tissue, &c.	1	1	2
Old Age	32	52	67
Violence, Privation, Cold, and Intemperance	44	26	26

PROGRESS OF MEDICAL SCIENCE,
INCLUDING CHEMISTRY AND PHARMACY.

France.

ACADEMY OF SCIENCES.

Meeting of August 17; M. Mathieu in the Chair.

The Gymnotus.—M. Matteucci forwarded a short description of the electrical apparatus of this animal. According to the author, this organ consists of a large number of galvanic batteries, which can act either together or separately; the strength of the discharge being always proportioned to the length of the part of the instrument which is thrown into action.

Researches on the Human Blood. M. Bonnet, of Lyons, has repeated the experiments instituted by Professor Dumas, for the purpose of ascertaining the action of the chloride of sodium on the globules of the blood; and the conclusions he has come to are directly opposite to those of the learned chemist. According to M. Bonnet, the salt, far from destroying, preserves the corpuscles. M. Dumas endeavours to account for this difference of opinion by stating that it probably depends upon the albumen of the blood, which M. Bonnet neglected to separate in his experiments, thus preventing the absolute contact of the salt with the globules. M. Bonnet has further remarked, that the hydro-sulphate of ammonia destroys the globules completely, and deprives the blood of the faculty of assuming the bright scarlet colour of arterialisation.

ACADEMY OF MEDICINE.

Meeting of August 18; M. Roche in the Chair.

The Plague.

M. Mélier, secretary of the Academy, handed in the following written amendment, to be discussed at a future meeting:—"The Academy expresses a desire that Government should call together a congress of delegates belonging to the different countries interested in the settlement of the quarantine question, in order to come to an agreement by common consent, on the duration and conditions of quarantines, and to make them obligatory to all nations concerned."

M. Sanson, in a letter, proposed a resolution analogous to M. Mélier's amendment, and also that "at least one ship be placed in the port of Alexandria, at the disposal of the authorities, in order to convey pestilential subjects beyond the reach of morbid influence."

M. Castel objected *in toto* to the report; the first conclusion was an assertion of truisms; all the others were merely the statement of facts, a sort of recapitulation of the various parts of the report, but not deductions from its arguments.

After some further remarks of M. Adelon, the meeting was adjourned at an early hour.

SOCIETY OF SURGERY.

Meeting of August 5, 1846; M. Chassaignac in the Chair.

Cataract.

Professor Berard presented to the meeting a crystalline lens of a stony consistency, which he had extracted under the following circumstances:—A lady, aged thirty-five, was since her birth blind in the left eye, and, fifteen years ago, on examination, the blindness was found to depend on opacity of the lens. Towards the end of the month of June last, without any apparent cause, the patient experienced a sudden pain in the head, and, on looking into the eyes, the lens was seen in the anterior chamber; a violent ophthalmia having supervened, was treated without success by antiphlogistic measures and purgatives; the removal of the lens was accordingly resolved upon. The division of the cornea was performed with a great deal of pain, and the lens was extracted; a broad strip of adhesive plaster was placed over the superior eyelid, and the inflammation gradually subsided after the operation, although it was followed by excessive suffering. Vision has not been restored.

M. Robert had seen similar cases, and would have followed the plan indicated by Sanson, viz., dividing the cornea in its upper part.

M. Nélaton attributed the displacement of the lens to the great dilatation of the pupil; he had observed that in these cases the passage of the lens into the anterior chamber usually took place during the night.

Aneurism.—M. Malgaigne related the case of a child who presented on one of the anterior branches of the temporal artery two small aneurismal tumours of the size of large peas, which he at first intended to operate upon by M. Petrequin's method of galvano-puncture. But, being unable to procure a proper battery, he merely passed pins through the tumours, and threw over each a twisted suture, which he left for twelve days in situ; at the end of that period the cure was complete.

Hydatic Tumour of the Womb.

M. Malgaigne then laid on the table a uterus containing an enormous hydatic cyst. The following is the history of the case:—

E. S., aged twenty-seven, had always been a woman of delicate health. Almost every day she was affected with sickness, and threw up bile and food; at eighteen she was married, and first menstruated only at the age of nineteen. Her first pregnancy, which took place soon after, was not attended with any peculiar symptoms, and she gave birth to a child who lived nine months, and died from convulsions. Twenty months ago she again became pregnant, and the child lived but one month; in both pregnancies the uterus was extremely distended, and the quantity of the amniotic fluid appeared unusually considerable. Since the month of May last the menses had not been observed, and, from the middle of June, the abdomen began to swell, and had attained at the end of July the size of an eight months' pregnancy. She was admitted into the hospital on the 24th of July, and complained of slight hemorrhage and continual vomiting; she also suffered from cramps in the legs, headache, giddiness, and loss of appetite. Examination per vaginam showed the os-tincæ to be extremely high, but healthy. Eight ounces of blood were taken from the arm, and the patient declared herself much relieved, the uterine hemorrhage having stopped. During the night of July 26, the discharge of blood reappeared, and with such violence that in the space of a quarter of an hour the two mattresses and the bed-clothes were completely soaked through. Notwithstanding cold lotions, and the application of a plug, the hemorrhage returned, and the patient died in the morning.

Dissection showed that the distended uterus occupied the whole abdominal cavity, and the womb, removed from the body, shot forth through the os-tincæ a considerable amount of arterial blood. The transversal circumference of the viscus measured sixty centimetres (twenty-two inches), and the perpendicular circumference sixty-six (twenty-five inches). On opening the uterus it was found to contain, not a fœtus, but an immense number of transparent vesicular bodies of the size of peas, attached to each other in bunches; no trace whatever of a placenta was detected. This mass did not adhere to the uterine walls; and in the fundus was noticed a surface larger than the palm of the hand, and deprived of that polished appearance observable in the other parts. The thickness of the parietes of the womb was from four to six lines.

M. Gosselin had no doubt that it was a case of diseased placenta. The special tissue was not, it is true, present; but similar instances have been repeatedly met with in which the placenta is positively visible, enclosing the hydatids, the formation of which causes the embryo to disappear.

M. Monod regretted that no effort had been made to arrest the fatal hemorrhage. He was of opinion that compression of the aorta ought to have been tried.

M. Robert then showed an astragalus which he had removed in a case of dislocation of the foot lately been placed under his care. We have, in a former communication (vide *Med. T.*, p. 342), published the case in the columns of the *Medical Times.*

Albuminous Nephritis in Pregnant Women.—This subject has been the object of the particular study of Dr. Cahen, late *interne* of the Parisian hospitals. The following is the result of his experience:—In pregnant, but healthy, women the urine is never albuminous; it should be tested with the greatest care where the patient complains of unusual lumbar pains, &c., when the lower extremities or the face are the seat of any œdema. Pregnancy seems to favour the production of albuminuria; and this complication is a frequent cause of premature delivery, and of convulsions. Indeed Dr. Cahen asserts that he never met, in any case, with albuminous urine during pregnancy, without the discovery being followed by one or the other of the accidents above mentioned. After confinement the urine generally returns rapidly to a healthy

condition; the anatomical alterations observed, after death from convulsions, all belong to those attributed to granular kidney. The best treatment consists in venesection.

HOPITAL DES ENFANS MALADES.

CLINICAL LECTURE BY M. GUERSANT, JUN.

DISEASES OF THE URINARY ORGANS.—Two cases presenting some common symptoms, although their nature is widely different, have been lately admitted into the wards. The first is that of a boy aged five years, pale, and slightly œdematous; for the last six weeks he has complained of pain in making water, and has dragged his urethra like children affected with calculus. These two symptoms, viz., infiltration, and difficulty in the emission of urine, point each to a different complaint: the first a disease of the kidneys; the second a foreign body, probably a calculus in the bladder. No eruptive fever has lately been observed, and the anasarca cannot be attributed, therefore, to that cause. Six weeks ago, however, the child having had sore eyes, a blister was applied to the arm, and the sore was dressed and kept open with cantharides. This fact led us to discover that the pain in making water was solely due to the mode of dressing the blister, which we at once changed. On testing the urine with nitric acid, it deposited a large proportion of albumen, thus leaving no doubt as to the nature of the complaint. A catheter introduced into the bladder failed in meeting with a calculus. A tonic regimen and gelatinous baths have been prescribed.—The second case is that of a child of the same age as the former, who also complains of pain during the emission of urine, and who also endeavours to lengthen his penis in order to get rid of an inconvenient tickling sensation. The child is usually well fed and enjoys good health. On examination of the bladder we detected the presence of a calculus, of the size of a hazel-nut, which appeared to us too hard and too large to be crushed. Lithotomy, besides, is generally so successful in children that we perform it as often as an opportunity occurs. We have now operated upon thirty children, five of whom only died; a sixth we also lost, but he was quite cured of the perineal wound, but caught the measles, and died of double pneumonia in our wards. We count, therefore, only five deaths out of thirty operations. It is not always after the severest operations for lithotomy that danger is most to be apprehended. In one child, who was cured perfectly, we had to introduce the scoop and forceps twenty-five or twenty-six times, in order to remove upwards of three ounces in weight of calculi.

GANGRENE OF THE LEG.—We have also admitted a little girl, aged ten years, affected with a gangrenous sore of the leg. When she was brought to hospital the child was already in the most unfavourable condition, both local and general: her constitution is very evidently scrofulous, and she had borne for some time an ulceration of the left leg, with a greyish fundus, clearly threatening gangrene. The sore at present occupies the entire of the external aspect of the leg from the malleolus almost to the knee: the muscles are denuded and gangrenous; the fibula, and several of the bones of the metatarsus, are disarticulated by the progress of the disorder. The chest presents no physical sign of consumption; but the tongue is dry, and the face slightly swollen. This is a bad case: amputation affords us but slender chances of success; however, it is the only one, and we would be guilty were we to neglect it.

HOTEL DIEU, LYONS.

ANEURISM AT THE BEND OF THE ELBOW, CONSEQUENT ON THE OPERATION OF VENESECTION.—GALVANO-PUNCTURE—CURE BY A SINGLE OPERATION.

We have already, on different occasions, noticed several cases in which aneurismal tumours have been cured by inducing coagulation of their contents by means of electricity. It gives us pleasure to be able to add another case, which was treated by M. Petrequin, of Lyons.

The patient, Edward Foucet, a student in pharmacy, aged thirty, living at Salins (Jura), had suffered during eight years from hypertrophy of the heart. For the relief of the urgent symptoms produced by this affection he underwent various modes of treatment, and placed himself under the care of Professor Chomel, of Paris. He was bled from time to time to diminish the palpitations from which he suffered severely. In February, 1846, he was bled by M. X., a surgeon at Arbois, who unfortunately wounded the brachial artery. A large swelling formed immediately, presenting the appearance of a simple ecchymosis, or infiltration of blood. As the primary swelling was absorbed, however, a small tumour became evident in the situation of the wound made by the lancet; this increased daily, and showed evident signs of pulsation. The patient became uneasy, and by the advice of Dr. Matuszewicz, a Polish physician, practising at Salins, he went to the Hotel Dieu, at Lyons, on the 8th of May, 1846, to be operated on by the galvano-puncture.

The hypertrophy of the heart was marked chiefly by a very distinct *bruit de souffle*, with prolongation of the first sound, violent motions of the heart over a large extent, and frequent palpitation. The aneurism at the bend of the elbow had been formed more than three months; it was larger than a pullet's egg, and was situated in the course of the brachial artery, forming a very prominent projection. At its most projecting part the cicatrix of the wound made in venesection was evident. The tumour was the seat of rapid, expanding pulsations, isochronous with the pulse, and which were very evident to the eye. The integuments were glossy, and the swelling gave an obscure feeling of fluctuation. No stratified coagula could be felt in the sac. A well-defined *bruit de souffle* was heard through the stethoscope, which ceased on the brachial artery being compressed above the tumour. The pulsations in the tumour ceased when the brachial artery was compressed between it and the heart, and it diminished in size also very considerably; compression on the distal side of the tumour produced no such phenomena.

Although the concomitant disease of the heart was an unfortunate complication, still it was not, in the opinion of M. Petrequin, sufficient to deter him from operating on the aneurism; but he wished to diminish the heart affection previously, if possible. For this purpose he confined the patient to a rigid diet; enjoined rest, and ordered soothing medicines, with sedatives internally, and the external use of belladonna over the cardiac region. After three weeks' perseverance in these means the disordered action of the heart had so far abated that M. Petrequin considered the patient in a fit state to undergo the operation, which he performed accordingly before Dr. Barrier, and a large number of pupils, on the 5th of June.

The patient being seated, with his arm extended on a table by his side, and supported by assistants, M. Petrequin inserted in the tumour four sharp-edged needles of seven or eight centimetres in length, so that their points should cross one another within the sac of the aneurism, as we have before described (see *Medical Times*, page 284). The person who had been desired to cover them with a coating of some non-conducting medium having neglected to do so, M. Petrequin used those needles without the coating. The battery consisted of sixty square plates of eight centimetres in diameter; and the layers of cloth were dipped in a solution of sal ammoniac. The assistant having compressed the brachial artery so as to stop the pulsations in the tumour, the heads of two of the needles were connected with the two poles of the battery by means of two brass wires, which were held by assistants, after being wrapped in silk. The galvanic current was very intense, and gave rise, at intervals, to brilliant sparks of a golden yellow colour. The shocks were violent, and the patient was supported in his place by assistants. The tumour at first decreased in size; it then became red and distended. The patient complained of a burning heat in the points where the needles were inserted, and a little cauterised eschar was produced round each of them. After ten minutes, M. Petrequin felt the thickness of the tumour increased; a kind of base became manifest in it, and it was evident that layers of coagula had formed. The action of the battery was still continued, each pair of needles being alternately connected with the poles. The patient was agitated, and experienced acute shocks; he fell into a profuse perspiration; but he was full of confidence in the result, and submitted with courage to the operation. After a continuance of the galvanic action during fifteen minutes, M. Petrequin felt that the tumour acquired greater hardness, and that no pulsation took place in it on removing the pressure from the brachial artery. Still, however, he continued the galvanic action for five minutes longer, by which time the sac had acquired a considerable density. The needles were then successively removed, and no pulsation returned. A ring tourniquet was then placed over the artery, and a bladder full of ice on the aneurismal tumour. The patient walked to his bed, but his limbs were relaxed and tired, as though he had undergone great fatigue. The day passed without any appearance of fever, the patient only complaining of the pressure from the tourniquet.

The next day he was better and more tranquil. The tumour was much less evident, chiefly because it was hidden by the swelling of the parts around it, caused by the compression. He was kept on a strict diet, with sedative medicines. The tourniquet was removed for an hour, and the tumour remained without pulsation. On the second day after the operation (June 7) the pulse reappeared, in the radial and ulnar arteries. The patient had slept well, and the forearm was less swollen. The tumour had already diminished considerably; it presented no pulsation to the touch, and no *bruit de souffle* on being examined by the stethoscope.

On the 8th the tourniquet was removed entirely. The forearm was not swollen, and the patient had slept well. He complained, however, of palpitations of the heart, which, without being more violent, were rather more rapid than before. In the evening the patient complained of acute pain in the bend of the elbow. The part was hot, notwithstanding the continued application of ice. M. Petrequin attributed this to the influx of blood consequent on the removal of the tourniquet. He prescribed a topical bath of cold water, into which the patient was directed to plunge the limb, and retain it for several hours. This gave immediate relief.

On the 9th the abnormal heat had nearly disappeared; it continued, however, in the bend of the elbow, which was painful on pressure. Inflammation of the aneurismal sac was evidently present; otherwise the patient's state was good, and he had a good appetite. On the 10th the tumour had nearly disappeared; it was, however, the seat of dull pain. The little eschars were about to become detached, and were surrounded by an areola of inflammation; two of them discharged a seropurulent matter. On the 12th the eschars separated one after the other, leaving openings by which a sanguinolent serum was discharged. The pain was relieved. On the 13th a blackish pus escaped, which the patient found very offensive. By making pressure around the seat of the aneurism, M. Petrequin pressed out little black lumps of coagulated blood, the debris of a semi-organized clot.

On the 14th and 15th suppuration of the sac continued, the aneurism had entirely disappeared, no vestige of it remaining, and the sac was empty.

On the 16th the arm had resumed its size and shape; the discharge had diminished, and M. Petrequin placed a compress over the sac in order to favour its contraction, and to obtain, if possible, adhesion of its walls. On the following day this was found to have produced an excellent effect. The wounds had become quite superficial, being no longer of greater depth than the thickness of the skin. Adhesions were established between the walls of the sac. The compression was nevertheless continued, and by the 20th of June the patient's cure was perfect. There was no longer the least trace of the tumour, and the radial and ulnar arteries pulsated naturally. On examining the condition of the heart, the palpitations were found to be less violent than before, but the *bruit de souffle* continued; the state of the patient's general health was, however, excellent.

On the 22nd he got up (having been previously kept in bed as a matter of prudence), supporting his arm in a sling. He took cold on the 24th,

and had a slight attack of fever with bronchitis, which detained him in the hospital till the 4th of July, when he was discharged cured. He afterwards presented himself before the Medical Society of Lyons, when pulsation could be felt throughout the whole course of the brachial artery, even in the situation of the wound. The motions of his arm were perfect, and his general state of health was good.

THE SPAS OF THE RHINE.

BY PROFESSOR TROUSSEAU AND DR. LASEGNE.

(GOUT—Section 6, continued.)

In old men passive gout becomes gradually established: in some few, indeed, the change which is brought on in their constitution by the progress of age is alone sufficient to produce a cure; but, in most cases the fits become irregular in their return and in their intensity. The symptoms threaten other joints before they fix upon their habitual seat. In these circumstances a debilitating plan of treatment is clearly to be rejected; it would seem more applicable to those aged persons who have preserved, to a certain degree, the constitution of their mature years, and who are still attacked with acute gout; but even here caution is necessary: reaction is slow in advanced age, and it must not be forgotten that many old persons have paid dearly for a sudden improvement, and have died because they had been imprudently cured. We, therefore, in old subjects mistrust the use of alkaline mineral waters, and cannot forget, that although a few of the aged have really preserved their strength, the greater number only enjoy apparent vigour, which is ready to yield at the slightest cause of disturbance; but in youthful plethoric subjects the Ems waters, on the contrary, succeed to a marvel. In these patients the symptoms and their prodromic signs are perfectly well marked, the paroxysms are regular, no tendency to displacement is observed: it is the disease in its normal state, horribly painful, but accompanied with no other disorders than those which generally follow acute suffering. In these cases the urine is highly coloured, and deposits an abundant sediment. Alkaline waters can then be prescribed with the greatest benefit: at the same time strict temperance must be observed; early hours, and exercise carried even to fatigue, will be ensured at the spas, by the excursions into the country, the change of habits, the new associations, and the necessity of rising early in order to drink the waters.

In atonic gout the treatment must be energetic in order to be useful, and, the patients experiencing only a trifling amount of pain, have no tendency to go beyond the prescriptions of their medical adviser. The progress of the disease is more insidious than in tonic gout, but it is not the less dangerous, and the physician requires all his acumen to recognise this Protean disease in its various disguises. It is in appearance a benignant, but in reality a very serious, malady, which constantly places the patient in danger, and gradually renders life insupportable. It is of these patients that Guy Patin said with much truth:—"If you have gout, you live in pain; if you have not, you live in fear." (Quand vous avez la goutte, vous êtes à plaindre; quand vous ne l'avez pas, vous êtes à craindre.)

We observe atonic gout often in patients who return cured after too long a sojourn at Ems or Vichy. The attacks have lost their vivacity; the disease is unsettled; the foot is numbed and heavy; the extremity is œdematous. Matters may continue in this state for weeks, and even months, without the occurrence of a paroxysm; the improvement is then slow, and occasionally sudden; abandoned to nature, these gouty subjects die of dropsy, or of the progress of anasarca. Their constitution destroyed by the use of alkaline substances, brings to mind the peculiar anatomical state of the inhabitants of fenny districts, who have long laboured under ague.

If any resource exists, the physician may still find it in the use of stimulant mineral wells—Hombourg, Kissingen, Kreutznach, Wiesbaden, for instance; they gradually give power to the reactions, and at last occasion a violent paroxysm of gout—one of those fits which the patient formerly was desirous of getting rid of at any price, but which he now regrets. A new regimen must be called in to assist the object the physician has in view: rich and delicate food, good old wine—the famous Pontay or Tokay for instance, which Hoffman prescribed with such pertinacity.

Atonic gout, which we might call also œdematous gout, is easily recognised. At Ems or Vichy it would grow incurable; at Hombourg it is speedily relieved. The gastric complications first yield, and a nourishing diet completes the restoration of the blood to its normal composition.

Under the influence of this powerful treatment the convalescents return through all the degrees of passive gout, and, if the medication be not arrested in time, they would be attacked with the acute symptoms of the tonic form. It then becomes necessary to moderate the treatment,—an uncommon occurrence, on account of the slowness with which such revolutions generally proceed.

In other and more insidious cases, the constitution of the patient appears rather plethoric; the attacks do not fail in vivacity, but the prodromic signs are slow in their progress; the respiration is embarrassed, or the digestion extremely difficult and painful. This form is exceedingly moveable. Many suffer from horrible gastralgia, or from asthma, before the appearance of the first attack. Unfortunately, in such cases, we are obliged to act often upon chance indications; these are much better marked, however, when the patient has already had one attack of gout: it is then that mineral waters can be most advantageous.

Hemorrhoidal patients afflicted with gout also deserve a separate study. The piles may have appeared before or at the same time with the gout: the latter occurrence is the more favourable of the two. To such patients Hombourg and Kreutznach are of use: they increase the intestinal congestion, and fully establish the hemorrhoids. By the combination of the dry and of the purgative cures the most happy results may be anticipated. Where, on the contrary, the piles have appeared before the gout, they seem much less closely connected with the articular disease: they interfere with the fits, diminish perhaps their violence, but contribute to increase their length, and to make their return irregular. We place for such cases much confidence in waters containing chlorides and carbonic acid. The increase of the hemorrhoidal affections will in all cases be serviceable to the gout.

A third class of gouty subjects presents the attributes of what is called the nervous constitution; these patients are troubled before the paroxysms with spasms, cramps, and agitation. If the gout displaces itself, it is chiefly the thoracic organs which are observed to suffer, asthma being frequently the result. The indications in these cases are far from being clear; when the gout is atonic the Hombourg wells will be found useful; and when it is a little more active, the Selters spas should be recommended. Perhaps to this form hydropathy would be more applicable than to the others; on this point, however, experience has not yet pronounced.

Such are the great practical divisions which we have thought it right to introduce into this arduous and complicated subject; but, if the types are true, still observation shows that they are often mixed and combined in the most embarrassing manner. Perhaps no patient is so difficult to observe and to direct as a gouty subject. We appeal to the recollection of those who have had to deal with them. The question we have attempted to examine is one of extreme delicacy; to say that such or such waters are good for the gout is absurd; we might as well recommend a medicine against headache, or another for the chest.

On the 1st of July the Society of Pharmacy of Belgium met at Amsterdam, in general assembly, convened for the purpose of promoting the interests of scientific pharmacy. This assembly resolved to memorialize the Government, demanding new laws to regulate the practice of medicine and pharmacy.

England.

INTERESTING CASE OF POISONING BY ARSENIC, IN WHICH NONE OF THE USUAL SYMPTOMS WERE OBSERVED.

BY J. H. HOUGHTON, ESQ., Surgeon to the Dudley Dispensary.*

Mr. Houghton was called at a quarter past eleven o'clock on the morning of the 15th of April last, to see Mrs. B——. He was immediately joined by two medical friends, and proceeded to her residence. He found her in a state of considerable mental excitement, but without any symptoms of cerebral affection. The patient told him, very collectedly, that about three-quarters of an hour previously she had taken half an ounce of arsenic, which she had that morning procured from a druggist in the town; and on inquiry it was found that she had been supplied with the poison.

She was, however, free from the symptoms usually attendant upon the ingestion of corrosive poison. She had not any thirst, pain, heat, or constriction of the throat or fauces, epigastric tenderness, vomiting, tormina, abdominal pain, or discharge from the bowels.

Mr. Houghton immediately applied the stomach pump, and in a short time the stomach was well washed out with water, and subsequently with soap and water. Albumen was then given freely, and afterwards doses of sulphate of zinc, which produced free vomiting. At twelve o'clock the hydrated peroxide of iron (made by adding liq. ammoniæ to a strong solution of sulphate of iron, as long as any precipitate fell, collecting the precipitate, washing it, and finally gently heating it, to drive off the ammonia) was given—a tablespoonful every five or ten minutes.

The patient was then put to bed, when she became composed, and almost free from pain, but had occasional gentle fits of vomiting, of a bilious character, this being the only symptom. Her pulse was rather feeble, and she soon seemed disposed to doze. This continued till a little past two, when Mr. Houghton left her for a time, with directions to continue the iron.

Shortly after Mr. Houghton left the house, her bowels were moved with some tenesmus, by which she was kept on the night-chair for nearly half an hour. At a little before three she was visited by a Mr. Roberts (who had previously seen her), and who found her in a state of collapse. He promptly applied external stimulants, and gave her small quantities of brandy-and-water and ammonia. (The iron was now discontinued, and not resumed.)

From this state of depression the patient never properly rallied, but remained quiet, dozing from time to time, but perfectly calm and collected, till twelve P.M., when she died. She presented no gastric symptom, except occasional mild vomiting; but whatever the stomach received was soon rejected; no tormina, tenesmus, or strangury; no cramp; and no cerebral or spinal symptom, to the last.

An examination of the body took place fifty seven hours after death. As, however, the presence of arsenic in large quantities was evident in the ejected fluids on the application of the usual tests, the stomach only was examined, out of respect to the wishes of the deceased's relatives.

At the pyloric end, on the posterior surface of the organ, a bright-red patch, nearly the size of the palm of the hand, was observed. On the posterior part of the stomach several streaks, about half an inch wide, of a black colour, and running from above downwards, but slanting from the cardiac to the pyloric end of the stomach, were observed. The intervening parts of the surface of the mucous membrane had a natural appearance. Where the black colour was less intense, a pinkish blush could be observed through it; and on washing the black deposit away, which was effected with difficulty, the mucous membrane beneath was found to be considerably inflamed. This black deposit was left wherever the mucous membrane was inflamed, excepting on the red patch near the pylorus, and nowhere else. It was most copious also where the inflammation was most severe.

---

* Condensed from a late number of "The Lancet."

There was not any destruction of the mucous membrane in any part of the stomach; it contained about three-quarters of a pint of darkish-green fluid, of the consistence of thickish soup. Small red vascular patches were seen on the small intestines, in various parts, as they lay *in situ*.

The contents of the stomach and part of the organ were reserved for analysis. The last sixteen ounces of fluid brought up by the stomach-pump were also reserved merely for experiment. The contents of the stomach, which were ejected by the sulphate of zinc, had been also reserved.

On Friday afternoon a little of the fluid, which seemed little more than coloured water, was added to a mixture of zinc and sulphuric acid, and the gas which escaped was burned by means of a jet. By holding a clean white china plate in the flame, a copious deposit of a bright metallic lustre was produced.

A portion of the same fluid was placed in a test-tube, and to it was added some ammonio-nitrate of silver. A bright-yellow deposit resulted. To a portion of the same fluid was added the ammonio-sulphate of copper. A bright-green precipitate resulted.

April 20. After the inquest, a part of the contents of the stomach was boiled in distilled water, filtered through charcoal, and the fluid submitted to the ammonio-sulphate of copper and ammonio-nitrate of silver without any result in either case. Some of the fluid was then added to a mixture of zinc and sulphuric acid as above; for the first minute or two a slight metallic-looking deposit was formed, after which no deposit could be obtained after frequent careful trials. A very small quantity of the fluid was now added to the mixture, when the accustomed metallic deposit was freely procured again. A little of the fluid was again submitted to the tests above described, with the same results as on Friday.

Tuesday, April 21. The reason of the slight deposit obtained the day before at the commencement of Marsh's test was now explained. The zinc which had been used on Friday was by mistake used again, and probably a slight portion of arsenic had adhered to it, and soon passed off. The stomach was now sliced into small pieces, and mixed with the remains of fluid; to it was added a little distilled water, and one-tenth part of pure hydrochloric acid. The whole was boiled in an earthen vessel till the stomach was completely dissolved, and filtered through some old linen. The fluid being very thick was diluted with a little weak hydrochloric acid. A part of the fluid thus obtained was boiled again, and, just before ebullition commenced, some thin, bright copper-plates were thrown into it, and boiled for half an hour. When the plates were removed, they had just the appearance of unwrought steel, as seen in steel warehouses, not bright or shining. The plates were carefully dried before the fire, placed in a small tube, and submitted to a gentle red heat in a spirit lamp. A slight black deposit took place in the tube, but no crystals could be observed with a common lens.

The tube was now broken, and boiled in distilled water for some minutes; the fluid thus obtained was submitted to the ammoniated nitrate of silver, producing a very faint and equivocal yellow tinge; and to the ammonio-sulphate of copper, producing an equally faint and equivocal green tinge. The remains of the fluid were reserved for further examination.

30. One ounce of the residue of the fluid was now boiled with two drachms of pure hydrochloric acid, and to this one drachm of pure nitric acid was added: this was diluted with a little distilled water, and filtered through charcoal. A clear fluid with the slightest lemon tinge resulted. To a little of this fluid was added, first, the ammonio-sulphate of copper, producing a bright green precipitate; second, the ammoniated nitrate of silver, when a thick white precipitate, very much like white lead was produced: this experiment was repeated when the same white deposit resulted, streaked however, with a clear yellow. Third, a stream of hydrosulphuric acid gas was passed through a portion of the fluid, when a very copious orange deposit resulted; the precipitate was collected and treated with black flux on a tube; some very minute specks of a steel-like appearance were observed in the tube by a common lens. Fourth, some of the fluid was now added to a mixture of zinc and sulphuric acid, in a common bottle, and the gas which escaped burned through a jet; the accustomed shining deposit was freely procured on a white china plate (the white deposit formed by the ammonio-nitrate of silver, which had been filtered and placed on one side, had now become almost blue). Fifth, to some of the fluid was now added a few drops of pure nitric acid, and then an excess of nitrate of silver; a copious white precipitate resulted; this was strained through filtering paper, and the clear fluid which resulted treated with ammonio-nitrate of silver, producing the accustomed yellow precipitate.

1. To some of the same fluid was now added a solution of prussiate of potash, when a bright, deep blue precipitate resulted; this blue was dissolved by ammonia, but not by the strong acids.

2. To some of the same fluid was added a solution of oxalic acid, when the whole became yellow, but without any deposit.

This case, Mr. Houghton very properly remarks, presents two especial points of interest.

1. The fact of half an ounce of arsenic having been taken for nearly an hour, and having produced scarcely any symptoms.

2. The effects of the antidote on the poison remaining in the stomach, after it had been carefully washed and emptied, as proved by analysis after death.

To the first point Mr. Houghton calls the particular attention of the profession, inasmuch as the absence of symptoms would be likely to lead any medical man into the belief that the patient was endeavouring to deceive for some unknown purpose. The treatment in Mr. Houghton's case was indicated solely by the account received of the poison having been taken, and not by the symptoms which it had produced, for, with the exception of some nervous excitement, no symptoms were present when the patient was first seen. An hour had elapsed without any effect having been produced: this is a longer time than generally intervenes, though cases are recorded in which the poison had been dormant two, three and even five hours. In these cases the patient had slept after taking the arsenic.

Comparing the symptoms existing in this case with those characteristic of the second class of symptoms produced by arsenic, as described by Christison, Mr. Houghton thinks he can scarcely say that they belong to that class. The only symptoms of narcotism being drowsiness and a feeble pulse, the case may be properly classed with a case by M. Labordes, quoted by Dr. Christison, in which the patient had no symptoms till forced to drink, when she vomited freely, but without uneasiness. In five hours she became drowsy, and died, complaining only of slight pain in the stomach. To this case it seems to form an exact parallel.

On the second point Mr. Houghton observes that the effects of the iron were very remarkable. With the exception of the "red patch" near the pylorus, every part of the mucous membrane which had been acted upon by the poison was thickly coated with iron, which it required considerable trouble to wash off with a sponge, as though the antidote had been attracted and firmly held by the poison, which, indeed, had so completely combined with it as to be incapable of detection upon repeated careful experiments.

Mr. Houghton inquires whether the absence of the iron on one "red patch" is to be attributed to that particular spot having been freed from arsenic by the means used to dislodge it?

The absence of free arsenic in the stomach after death, and the evidence of abundance of it after means had been taken to set it free, are facts of the greatest practical importance. They form strong corroborative evidence of the value and efficacy of the iron as an antidote, and hold out the strongest inducement to administer it promptly and freely in cases where arsenic has been taken in poisonous doses.

ORIGINAL LECTURES.

A Course of Lectures on Practical Midwifery.

By EDWARD RIGBY, M.D.,

Fellow of the Royal College of Physicians, Senior Physician to the General Lying-in Hospital, Lecturer on Midwifery at St. Bartholomew's Hospital, Examiner on Midwifery to the University of London, &c.

Delivered last session at St. Bartholomew's Hospital, and revised by the Professor for the "Medical Times."

TREATMENT OF AFTER-PAINS. MECHANISM OF PARTURITION.

At our last meeting, gentlemen, I promised to commence this evening the subject of the mechanism of parturition. Before doing so, however, I have a few words to say to you on the pains which continue during a variable period after labour. We find these pains after most labours, but they vary much both in duration and severity. They are always most severe in women who have borne many children, and in some multiparæ they continue from twenty-four hours to three days. These pains, in common with those of labour, depend on contraction of the uterus; and these contractions are kept up after labour by the presence of the lochia or of coagula of blood, or of shreds of membrane in the cavity of the uterus. The afterpains, therefore, you will easily understand, are essential to the due emptying of this organ. Afterpains are not usually felt in primiparæ. In multiparæ, when the woman is quite healthy, they seldom continue very long. When very severe, and of very long continuance, they may be considered as indicating the presence of inflammation, or, at all events, of a state bordering on inflammation. The pain no longer comes and goes in distinct intermissions, but it gradually becomes constant; the uterus, too, becomes tender on pressure, and the other symptoms of inflammation are established, but we shall have to consider this subject hereafter when speaking of puerperal fever. You must, however, bear in mind, gentlemen, that long-continued and severe afterpains may form an insidious transition to a state of inflammation.

The treatment pursued during the last few days of pregnancy has great influence in modifying the afterpains. If the woman be allowed to go even up to the period of her labour with her bowels confined and loaded with unhealthy fæces, and with the secretions of the primæ viæ disordered, the uterus seldom contracts well during labour, and, under these circumstances, afterpains are sometimes very severe. The too rapid expulsion of the placenta, and the hasty conclusion of the last stage of labour, so that the uterus does not contract fully and firmly, are also causes of the contractions which cause these afterpains; and in these cases the afterpains are useful in expelling the clots and lochia which, if allowed to remain, would become putrid, and thus prove a source of irritation, and, perhaps, give rise to puerperal fever. When the practitioner neglects to apply the child to the breast as soon as labour is concluded, the uterus does not contract fully, as I have before told you; this, therefore, is another reason for early suckling. In speaking of the application of the child to the breast, I believe I forgot to mention to you the fact of nurses having a saying that "the child brings afterpains." This occurs to a great extent when the infant is not applied to the breast until the third day, and is, therefore, another reason, if more were required, for its early application.

Although afterpains are commonly, no doubt, excited by the presence of coagula in the cavity of the uterus, still they may sometimes occur when no such coagula are to be found. On this subject Dr. Burton, of York, who published in 1751, has given some curious observations which I shall read to you, as, in my opinion, he explains one cause of afterpains very satisfactorily. Dr. Burton says, "Upon the expulsion of the child and the placenta, the orifices of the uterine sinuses must contract, and thus retain the grumous blood which is in them; hence the use and benefit of these afterpains, which, by stimulating and compressing the vessels

and muscular fibres, make them exert their force to squeeze out this grumous blood, which otherwise might remain there and occasion inflammation, suppuration, &c.; from all which we find that these afterpains are necessary towards removing or preventing an inflammation of the womb; therefore, we must not be too forward in giving strong opiates, and other internal medicines, which may take them off whilst this grumous blood is lodged within those sinuses. I doubt not," continues Dr. Burton, "that those patients who die from the eighth to the fourteenth day, whose uterus has been inflamed with the symptoms above mentioned, have been injured by the too free use of opiates." The discharge, gentlemen, in these cases contains little vermiform shreds, and these shreds do not consist of portions of membrane which have been left behind, but they are the casts or moulds as it were of the cavities of the blood-vessels, and are composed of their contents coagulated. Dr. Burton mentions a case to which he was called, in consequence of severe afterpains coming on sometime after labour; in this case, having introduced his hand with some difficulty, he perceived several small membraneous strings, as he then thought them, adhering to the uterus; but, he says, "I was soon undeceived, for, upon expanding my fingers, by which I stretched the womb a little, several of these came into my hand, which I drew out, and found what I had imagined to be membranes to be only oblong grumous blood resembling fibres like those that adhere to a spatula after stirring arterial blood in a basin for some time. I introduced my hand a second time," he continues, "and made the experiment again, but found none of these little clots within the cavity of the womb; yet, upon expanding my hand, several came out of the orifices again which I could plainly perceive, and, after keeping my hand there a little while, I brought away all that were in the cavity of the uterus, and the patient's complaints immediately abated, and she recovered well from that moment." These little vermiform fibres are, therefore, you see, gentlemen, the casts of the blood-vessels, the contents of which had coagulated, having been retained by the contraction of their orifices. By being careful not to hasten the last stage of labour, so as to give the uterus time to contract slowly, the uterine sinuses expel their contents, and the annoyance of afterpains is, in many cases, altogether prevented.

It was formerly the practice always to administer a large dose of laudanum to check these afterpains; and a most pernicious practice it was, and one which, I am happy to say, has diminished considerably of late years. As much as forty minims of tincture of opium were administered as a rule in all cases by some accoucheurs. I need hardly point out to you the falsity of the reasoning on which this practice was founded. Opiates should never be given for the purpose of checking afterpains, unless they are very severe, or in some peculiar cases which will come under our consideration hereafter. Should your patient, however, have been accustomed to an afterpain draught, as it is called, and seem to expect it from you, you can give her a little tincture or extract of hyoscyamus or of lettuce. A mild sedative may, however, in many cases be useful after labour, as when the system is in a state of irritability and restlessness, consequent on the fatigue and irritation of a lengthened period of suffering; but in these cases a small dose of Dover's powder or of the sedative solution of opium will always prove sufficient. When afterpains continue very severe for some time after labour, your best plan of treatment will be to give the customary dose of castor oil a little earlier than usual; you will generally find that this will relieve the pains on bringing away a quantity of fecal matter. When the pains continue very severe in spite of this treatment, you will, as I have before said, suspect the presence of inflammatory action, and you will act accordingly.

I now come, gentlemen, to the consideration of the mechanism of parturition—a part of my subject which it is of the utmost importance for you to understand fully and clearly, as without it you will find yourselves at sea completely when you come to practise the art of midwifery, and upon the accuracy of your knowledge and the clearness of your comprehension of it much of your success in after-life will depend.

Previously to entering on the mechanism of parturition, properly so called, or the passage of the child through the pelvis of its mother, it is necessary for me to describe the pelvis to you; and, first of all, I shall mention to you the differences between the male pelvis and that of the female. You will perceive, gentlemen, that the male pelvis, which I now show you, has a narrow contracted brim, with the promontory of the sacrum projecting forwards very considerably; the whole contour of the brim, too, is quite different from the same part in the female pelvis, which I now hold in my hand. In the male you see the brim is round; in the female, on the contrary, you perceive it is oval. You see, too, in this, the female pelvis, that the promontory of the sacrum does not project nearly so much as it does in the male. In the male the ossa ilii are placed more vertically; whereas, in the female, they are more expanded, and not so deep. This difference in the formation of the iliac bones is of considerable importance, as, from their width in the female, they tend to support and protect the gravid uterus. You perceive that the pelvis of the two sexes differs much also in its cavity: that of the male pelvis being deep, that of the female shallow, more approaching to a ring of bone. This distinction is very evident at the symphysis of the pubes, the depth of which in the male is generally about an inch and a half, whereas, in the female, it seldom exceeds three quarters of an inch. This difference in depth is of considerable importance when considered in relation to parturition. The less the pelvis is in depth the less will be the surface on which the pressure of the child's head is exerted, and, therefore, the less will be the resistance. The cavity of the pelvis is generally deeper in tall than in short women, and on this account, *cæteris paribus*, tall women generally have more tedious and difficult labours than short. The deep hollow of the sacrum in the female pelvis also materially assists in rendering parturition easy: it allows the head to descend without making the injurious pressure on the soft parts lining the pubic bones which it otherwise must produce; and this is particularly of importance with regard to the bladder, as its neck must suffer in all labours if the hollow of the sacrum did not receive the head in its transit, and relieve the anterior parts from its pressure. The obturator foramina and the ischiatic notches are larger in the female than in the male pelvis, and the bones of the female pelvis are generally slighter and less massive. You perceive that in the outlet of the pelvis the difference between the two sexes is very apparent, and in no part is this difference more evident than in the pubic arch. This arch, you perceive, in the male, is narrow, contracted, angular, and deep, and the edges of the rami of the pubic bones are sharp and distinctly defined; in the female, on the contrary, you perceive that the pubic arch is shallow, broad, and well rounded, and the edges of the rami are rounded off as it were. When I place these two pelves side by side you will see this contrast very strikingly, and it is even more marked in the recent pelvis on account of the additional difference between the sub-pubic ligaments. You will easily understand that this difference has a material effect in assisting the process of parturition. The tuberosities of the ischia, too, are smaller and much farther apart in the female pelvis than in that of the male; the coccyx is more moveable, and the sacro-ischiatic ligaments are longer, so that the coccyx can be forced backwards to a considerable extent.

It is of some importance for you to understand correctly the differences of the different diameters of the female pelvis, as without this knowledge you can never be perfectly acquainted with the mechanism of parturition—a good knowledge of which, gentlemen, I must repeat, is absolutely necessary in order that you should become successful obstetricians. The diameters of the brim, cavity, and outlet of the female pelvis may be given correctly enough, for all practical purposes, by measuring their dimensions in three different directions—1st, the straight, antero-posterior, or conjugate; 2d, the transverse; and 3d, the oblique. I will write these dimensions in a tabular form on the board, in order that I may the better explain them to you.

	Antero-posterior.	Transverse.	Right Oblique.	Left Oblique.
	Inches.	Inches.	Inches.	Inches.
Brim	4	5	4½	4½
Cavity ...	4	4	4½	
Outlet....	3½*	4	4½	

In the brim the antero-posterior, or straight diameter, is drawn from the promontory of the sacrum to the upper edge of the symphysis of the pubes. In the cavity this diameter is drawn from the middle of the hollow of the sacrum to the middle of the symphysis of the pubes; and at the outlet this diameter is taken from the point of the coccyx to the lower edge of the symphysis pubis. The transverse diameter at the brim is drawn from the centre of the linea ilio-pectinea of one side to the same point on the opposite side. In the cavity the measurement for this diameter is taken from opposite the lower edge of the acetabulum on one side to the corresponding point on the opposite side, and at the outlet it is measured from one tuberosity of the ischium to the other. The oblique diameters at the brim are drawn from one sacro-iliac synchondrosis to the opposite acetabulum; in the cavity from the centre of the free space formed by the sacro-ischiatic notch and ligaments on one side to the obturator foramen on the opposite side, and at the outlet from the middle of the lower edge of the sacro-sciatic ligament on one side to the point of union between the ischium and descending ramus of the pubes on the other. The oblique diameters are named right and left according to that sacro-iliac synchondrosis from which they are drawn. These dimensions may vary a few lines in different pelves; but, I believe, I need not trouble you with these variations, as I have given you the general diameters near enough for all practical purposes. The oblique diameters in the cavity of the pelvis have the advantage also of being lined by yielding substances, as they are bounded by the sacro-ischiatic ligaments posteriorly, and the obturator ligament anteriorly. You must bear in mind, gentlemen, that the dimensions I have given you are those of the skeleton pelvis, and that, of course, they vary much during life from the numbers I have written on the board. The great masses of the psoas and iliacus muscles fill up very much, to say nothing of the numerous smaller muscles and the different organs contained in the pelvis. These muscles, too, during parturition are thrown into violent action, and their bellies, of course, become swollen, so that during labour the transverse diameter, which in the dried pelvis is the longest, becomes actually one of the shortest. The oblique diameters, therefore, are, during life, the longest available for the passage of the head. We shall see the application of this fact by-and-by. Now, as regards the diameters of the fœtal head: a great many measurements are given in books—so many, indeed, as to be quite confusing—I shall give them to you in general terms. The transverse diameter is three inches and a half; the occipito-nasal, or great diameter, is four inches and a half; the perpendicular measurement is three inches and a half; and the occipito-mental five inches.

Little attention was paid to the mechanism of parturition until the latter part of the last century; before that the most gratuitous and incorrect assumptions were made respecting the manner in which the presenting part of the child enters and passes through the pelvis. And even up to the present time I am sorry to say, gentlemen, that these erroneous opinions are held by some persons, who, from their positions as lecturers and teachers of midwifery, possess ample opportunities of attaining more correct views. Because the occiput usually comes forwards during the passage of the head under the pubic arch, it has been assumed that the head takes this position on entering the pelvis; that is to say, that the long diameter of the head enters the pelvis in its antero-posterior diameter, which

* This diameter is increased during labour by bending back the coccyx to 4½ inches.

by a reference to the board you will see is the shortest diameter of the brim of the pelvis. Mauriceau, La Motte, Levret, Stein, &c., maintained this opinion. The first practitioner who attempted to rectify this great error was Sir Fielding Ould, physician to the Lying-in Hospital at Dublin. He published a treatise on midwifery in 1742, in which he stated that the head at the commencement of labour has its long diameter directed in the transverse diameter of the pelvis. Smellie, who published his work on midwifery in 1752, thought the same. Smellie differed from Ould, however, on one point. Ould had stated that the shoulders at the commencement of labour took the same direction as the head. Smellie maintained that the shoulders, until they entered the pelvis, had their transverse diameter parallel to the antero-posterior diameter of the pelvis. You will see, however, gentlemen, that although Ould and Smellie were nearer the truth with regard to the passage of the head, neither of them was exactly right. Up to 1770 nothing was known on this subject in France; but about this time Deleurie first published his "Traité des Accouchemens," in which he embraced Smellie's views entirely. This was the first change which took place in the ideas on this subject in France from the time of Mauriceau. In 1771 two authors published inaugural dissertations on this subject almost simultaneously, and certainly quite unknown to each other: one of these was by Matthias Saxtorph, of Copenhagen, and was entitled, "De diverso partu ob diversam capitis ad pelvim relationem mutuam;" the other was published at Paris by Solayres de Renhac, professor of medicine at the celebrated School of Montpellier, written on the occasion of his being admitted into the Royal College of Surgery. This dissertation was entitled, "De partu Viribus Maternis absoluto." Solayres, however, died immediately after its publication, and before he had been called on to defend his views. These two were the first authors who gave a correct description of the mode in which the child enters the pelvis, viz., with the sagittal suture parallel to the oblique diameter of the pelvis.

The famous Baudelocque translated Solayres de Renhac's treatise into his great work on midwifery, and Plenck has copied, without acknowledgment, Saxtorph's dissertation into his "Elementa Artis Obstetriciæ." All later writers on this part of the subject have been contented to copy Baudelocque.

At our next meeting, gentlemen, I shall describe to you the positions of the head.

A Course of Lectures on Diseases of the Skin.

By JAMES STARTIN, Esq., Surgeon to the London Cutaneous Institution.

LECTURE XXI.

HERPES.

According to Willan and others.

	SPECIES.
Herpes	H. Phlyctænodes
	H. Zoster
	H. Circinatus
	H. Labialis
	H. Præputialis
	H. Iris

As proposed by Startin.

GENUS AND SPECIES.	DIVISIONS.	
HERPES		
H. Phlyctænodes	Localis	Sparsus
H. Iris vel versicolor		Confertus
H. Diutinus circinatus	Pluri-localis	Annulatus

GENTLEMEN,—Until the close of the last century the term *Herpes* (which is that affixed to the next cutaneous malady on which I am desirous of engaging your notice) was applied indiscriminately to nearly all eruptions of the skin, accompanied by scurfiness, vesicles, pustules, or eroding sores. This definition, it must be obvious, would include many diseases totally different in their origin, nature, and treatment. As usual, the great authority for the present application of the term is Willan, who, in this instance, has undoubtedly produced something like precision and order out of what, before he gave his time and attention to the subject, was inextricable confusion. Willan has limited the disease to a vesicular eruption, mostly of an evanescent nature, having a course or progress more closely resembling the true exanthemata, than any other chronic affections of the skin; that is to say, a period of seven to fourteen days is for the most part sufficient to comprehend the rise, maturity, and decline of the disease, whilst more or less constitutional disorder attends nearly every case, subsiding as the malady disappears. Herpes may, therefore, be defined to consist in a noncontagious cutaneous eruption of distinct vesicles, seldom larger than a small pea, which are filled with a watery fluid. These vesicles occur in groups, rings, or clusters, on an inflamed base, mostly extending a little beyond the seat of the eruption; the progress of the disease being attended by constitutional disorder, and usually terminating in a week or ten days by superficial scabbing, and more rarely by ulceration. The situation occupied by the vesicles of herpes, for the most part, will be found placed over a superficial nervous centre or ramification, which the disease follows in such a manner as to cover that portion of the side, or half of the body, or limb, to which the nerve is distributed, consequently much pain, smarting, and tingling are the usual symptoms attendant on the disease. Herpes, though a local disease, may be manifested on one or more parts of the body; and age, sex, or condition in life appear to exert no marked influence over its attacks. Some individuals would appear to be particularly liable to attacks of herpes, whilst others, even amongst members of the same family, under precisely the same circumstances, would seem to possess a species of immunity, as they are never sufferers from the complaint.

The contents of the vesicles, on their first appearance, are commonly clear like water, but become milky and opaque after a day or two, when they usually break, and sometimes discharge an abundance of this serosity. When this occurs, ulcerations are apt to follow, and the scabbing and healing process may be long delayed.

It will be perceived from the foregoing brief definition and description of this common disease, that it very much resembles pemphigus, already considered, and, indeed, I can discover no practical difference between one disease and the other—the greater extent of eczemation in pemphigus constituting a difference, without a distinction leading to any useful result. By examining the models before you, I think my remarks will appear still more reasonable, as the greater inflammation around the vesicles of herpes (forming a rose-coloured ground from which they spring), in reality, is the only visible difference between one affection and the other, when the eruptions are of corresponding magnitude. There is also a species of herpes not found in the authors I have consulted, and of this you have two examples on the table: this I have named on the chart *Herpes diutinus*; it seems to form the connecting link between Pemphigus diutinus, Herpes, and Eczema, if, indeed, the size of the vesicles would not refer it to the first-named complaint.

I have proposed to call this malady *Herpes diutinus circinatus*, from its very constantly remaining for a lengthened indefinite period, and appearing commonly in a circular figure; but I may refer you to the chart for the arrangement I propose adopting, which you may notice comprehends four species of herpes, which are similar to those of Willan, except the last: they are named H. Phlyctænodes, H. Zoster, H. Iris vel versicolor, and H. diutinus circinatus; the divisions of this species are local and variously placed, whilst the forms are scattered, grouped, and annular. Willan attached distinct names to the local divisions, which furnished additional species called, after the parts affected, *H. labialis*, *H. præputialis*, &c. &c.; these varieties are, in reality, Herples simplex, otherwise called phlyctænodes, affecting these portions of the body. I cannot think that it is necessary for me to describe at length each variety of herpes; yet, as the editor of the *Medical Times* does me the honour to print what I say, it may be well to make the subject complete by briefly recapitulating the chief characteristics.

H. Phlyctænodes or simplex may serve as an example for the whole group. It commonly commences after a few days' indisposition, first by pain and heat in the part about to be affected, which in an hour or two assumes a redder tint than the surrounding skin, and a sensation as though the part were excoriated is experienced. A few red spots now become visible, from eight to twenty in a cluster, which very speedily appear to be vesicles that in ten or twelve hours may attain the size of a small pea, the inflammation from which they spring extending a little beyond each cluster, as you will observe in the model I hand round. In a few days these vesicles break and shrivel up, leaving here and there a small loose scab or crust, which remains adherent for a short time and then falls, leaving a red mark on the skin, which lasts several days.

If the complaint be irritated or disturbed, it is apt to ulcerate and to be of longer duration. This elementary form of herpes may appear in succession on several parts of the body, but it is best known on the lips and prepuce, where, according to Willan's nomenclature, it is called *H. labialis* and H. præputialis. I may observe that when this herpes attacks the vicinity of any of the openings of the body, as the nose, the outside of the prepuce, &c., it is apt to extend within these parts, but I do not know that these migrations are of any practical importance.

H. Zoster, well known by the vulgar appellation of Shingles, is the most important and interesting of the genus under our consideration. Tradition or superstition has attached an importance to it which I cannot think it deserves, and a prejudice has existed, even since the days of Pliny,* who mentions the circumstance that in the event of shingles forming an entire zone round the body, the consequences will be inevitably fatal. When you remember what I have mentioned respecting the mode in which herpes follows the ramifications of some one particular nervous trunk supplying the skin of any part of the body (some as yet not understood irritation in which nerve being the probable cause of the complaint), you will perceive that, as all our nerves are double, it is unlikely the body can be encircled with herpes unless both nerves should be simultaneously disordered, and consequently, that it is prognosticating against a contingency, which is most improbable, if not impossible. Herpes zoster is very constantly preceded by two or three days indisposition, attended with feverishness and rheumatic pains, which are sometimes exceedingly severe in the part which becomes the future seat of the disease; an eruption of sundry red blotches, distributed in no regular order, next manifests itself on the side of the body, as for example on the abdomen, as witnessed in the model before you; or it commences at the median line either in front or behind, extending, as the nerves are known to do, very accurately over that half or side on which it commenced, reaching thus from the spine to the centre of the sternum, like a zone or belt, or rather a half zone or belt, whence its name, Zona or Zoster. Occasionally, also, the form of herpes follows the distribution of the superficial nerves on the limbs and other parts. In the example before you this was the case, the cutaneous nerves accompanying the superficial epigastric and external circumflex ilii arteries, which arise beneath Poupart's ligament from the femoral trunk, and supply the skin of the left hypogastric region, and the upper and outer part of the thigh, being the filaments which appear to have been concerned in the production of this shingles.

To proceed, however, with the description of herpes zoster, the red patches I have spoken of soon become vesicular, the vesicles having often a flattened appearance, and an arched figure like a small haricot bean (this is also observable on the models). In three, or at most four, days, the vesicles have a darker appearance, as though they contained a little bloody serum, which, indeed, is commonly the case before they break or become shrivelled up, when a slight encrustation occupies their place, and ultimately falls, leaving a red spot on the skin. The whole course of the malady is usually completed in a week or ten days. Herpes

* 1 Pliny, 2 Id.

iris or versicolor, the next species of the disease, very rarely witnessed; I may have seen it half dozen times: it is Herpes phlyctænodes occurring on a delicate florid skin, with the transparent vesicles so arranged as to reflect the light in prismatic colours like a rainbow. No practical importance attaches to this disease, which is a mere matter of curiosity and has served cutaneous delineators with an opportunity for exercising their predilection for vivid colours—a chance which, as regards this complaint, has never occurred to our modeller since his employment here.

Herpes diutinus circinatus, the name I have ventured to attach to a variety of herpes I have many times witnessed, which is exemplified by two models, commences, like the simple species, by a sudden eruption of vesicles in one or more parts of the body, their arrangement being very constantly annular (the *H. circinatus of Willan*). At first the disease appears to follow its ordinary course; but when in other species it should disappear, a second eruption of vesicles is manifested, and these are of a larger size, and occur a little beyond the boundary of the former circle, whilst the first site of the disease remains raw, and sometimes ulcerated. Vesicles at the same time are produced in the centre of the rays, and go through a similar process, until at last a round or oval vesicular, excoriated, and ulcerated patch is formed, often becoming as large as the palm of the hand; in short, the disease assumes the appearance the models represent, one of which is taken from the leg, the other from the arm of different patients. The head occasionally becomes the seat of this complaint, when it constitutes a variety of vesicular ringworm that is very troublesome and difficult of cure—the ordinary herpes circinatus of the scalp being amongst the most simple and readily alleviated of any of its affections. I beg, however, that you will observe the models of herpes diutinus circinatus, which, better than any descriptions, will render you familiar with it appearances. In so doing you will not fail to remark how closely it approximates in its appearance and nature to eczema figurata and pemphigus.

A few words only can be required on the treatment of the common forms of herpes; in fact, the less the complaint is interfered with, in ordinary cases, the better. I generally confine my recommendations to dusting the parts twice a day with hair powder, and directing a saline acidulated aperient, containing, when much pain accompanies the shingles, a few drops of the wine of colchicum.

In *Herpes labialis*, a lotion, containing a little borax, is often of use, and gentle purgatives are always expedient. The models of these diseases point out the appearances usually presented; and I shall not detain you longer on a subject so unimportant by a recital of cases, as the little medical management they may require must suggest itself to a tyro in the art of healing. I have found the variety, named herpes diutinus circinatus yield to the treatment recommended when speaking of eczema: in one of the examples on the table, the diseased patches had existed a year, and in the other from the arm, upwards of two years; they required about six weeks' treatment, local and constitutional, before they yielded, and a slight cicatrix remained on the spots they occupied.

When I treat of ulcers, I shall again have occasion to make mention of this species of herpes; and on a future occasion its complications with syphilis and scrofula will require especial mention; yet, before I conclude with this subject, it may be well to make an observation or two on *Herpes Præputialis*, which from its situation is very apt to be mistaken for another disease. I have known the peace of families destroyed, by this mistake, in more than one instance; whilst the unfortunate victim of the error has been treated with mercury, and what not, with a view of eradicating syphilis! If the poor wife should have leucorrhœa (which, I may observe, is nearly always the case, and, indeed, seems to be the common cause of this herpes in the male), the supposition of a syphilitic origin of the excoriations or ulcerations becomes verified, and she, too, becomes a martyr to the mistake. A train of evils thus commences, which all medical efforts, however well directed, very commonly fail to check, until a serious state of things is created. The well-known remarks, on what he termed pseudo-syphilis, of my friend and teacher the late John Abernethy will recal many of these cases to the recollection of those familiar with his writings or lectures, as he paints in never-to-be-forgotten colours the symptoms and treatment of these often afflictive cases. I should advise you in all instances of doubt to give the unfortunate patient the benefit of the doubt, not only in the disease under our consideration, but whenever your opinion is called for by a public or private tribunal, or any professional circumstance which may destroy the peace or happiness of a fellow-creature. I am induced to dwell on this point, at this moment, from the fact that last week only the circumstance I have supposed was actually presented to my notice. A highly respectable and talented barrister posted from a midland town with these suspicious appearances on his prepuce and glans penis. He had consulted several practitioners, and had been led to believe that he must either have contracted syphilis, or that the secondary appearances of this disease, for which he had taken mercury in his youth, were now manifesting themselves, to embitter and destroy his matrimonial happiness. He was again taking mercurials, and had made up his mind for the worst. I examined the parts with care, and listened to his recital, when I was happy to assure him that the offensive discharges, the small ulcerations covered with white coagulable lymph, and the burning heat and irritation in the part of which he complained, were the usual symptoms of herpes præputialis, and that, as the eruption had existed a week, the use of a little mild black wash, and an antacid aperient, would suffice to make him well in a few days. I need scarcely assure you that my prognostication was verified, and it brought this conviction to the mind of my patient, that, on the former occasion, when he had been salivated for syphilis, his complaint was identical with the one from which he had now recovered. I propose next week, gentlemen, to consider the affection of the skin termed *Aptha*, and to furnish you with a brief recapitulation of the diseases heretofore considered, so as to give you an insight into the reasons for the order observed as regards their description, before I commence the detail of what may be termed a *new series* of these complaints, not having the characteristics of discharges or encrustations as their usual attendants, which, as you will have remarked, has been the case in every instance we have at present reviewed.

ORIGINAL CONTRIBUTIONS.

THE NERVES OF THE UTERUS.

By T. SNOW BECK, Esq.

[To the Editor of the Medical Times.]

SIR,—By the letter from Dr. Knox, which appears in your number for August 15, it might be supposed that the observations made by that gentleman, after an examination of my dissections, were published by Dr Robert Lee, in consequence of a letter which I had previously published. The facts, however, are as follows:—Dr. Robert Lee published, in the "Literary Gazette" for May 2, what purported to be a short account of Dr. Knox's interview with me. This I considered a very erroneous statement of what had occurred, and I wrote a letter in the next number of the same journal for May 9, with the view of correcting the mistake. This letter of mine was followed by a more lengthened account of Dr. K.'s observations, which I declined answering at that time, feeling that it was most unfair and unscientific to commence the discussion of a subject which had not appeared before the profession.

After the lapse of three months and a half from the time at which Dr. Knox examined the dissections, and while the paper was yet unpublished, Dr. K. observes—"But perhaps it is right that I should notice this (Mr. Beck's) letter *now, when all the circumstances are fresh in my memory*." Dr. K. also says that my letter "may be true, and probably is quite true, but it does not contain the whole truth." Yet, before saying this, Dr. Knox ought to have remembered that the letter was only intended to answer the points spoken of in the first report of his remarks (May 2). However, as the number of the "Philosophical Transactions" which contains my paper "On the Nerves of the Uterus" has now been published, I will examine the objections contained in Dr. Knox's letter in your journal for August 15, and in Dr. Lee's report printed in the "Literary Gazette" of May 16.

I think the chief of the objections may be arranged under the following heads:—

1. The removal of the sheath of the nerves.
2. The small number of nerves which accompany the arteries.
3. The peculiar character of the pelvic plexus.
4. The condition of a long nerve which runs up by the side of the uterus.
5. The occurrence of divided ends of supposed nerves in the tissues of the uterus; and
6. The large amount of nerves on the vagina when compared with those sent to the uterus.

1. The removal of the sheath.

This, Dr. Knox observes, is "Mr. Beck's peculiar and unwarrantable mode of conducting the dissection. Mr. Fergusson agreed with me, that when we begin to open the sheaths of nerves, especially those of the sympathetic and its ganglia, the destruction of a great part of the nerves and ganglia must be inevitable."

"The dissections of Scarpa, Walter, Lobstein, and all anatomists, might be objected to, if the sheaths of the nerves are once touched."—*Literary Gazette*, May 16.

"By opening the sheaths of the nerves to such an extent as Mr. Beck has done, the nervous character is apt to disappear and to be confounded with the cellular tissue; under this mode of dissection ganglions assume a new form, the grey matter is scraped away, and what appeared a single ganglion becomes a group of ganglions marked by plexuses of a peculiar character, and such as I had not seen before."

"Mr. Beck and his friends attach much importance to the opening up of the sheaths of the nerves, separating the component fibrils, dissecting the ganglions so deeply as to remove in as far as possible all that is not nervous matter. Now, there can be no objection to this as an object of close inquiry; but, in the first place, the method is *far from novel*; and, in the second place, it is difficult to see where it is to end."—*Medical Times*, Aug. 15.

It would thus appear that Dr. Knox is not very decided in his opinion as to what has been done, or what ought to be done, with the sheath that surrounds the nerves. He first says that to remove it is "Mr. Beck's peculiar and unwarrantable mode of conducting the dissection"; and afterwards, that "there can be no objection to this as an object of close inquiry; but in the first place the method is *far from novel*."

He next says that the sheath must not be touched; for "when we begin to open the sheaths, the destruction of a great part of the nerves and ganglia must be inevitable"; and then leaves one to infer that it may be partially removed, but if "*to such an extent* as Mr. Beck has done, the nervous character is apt to disappear, and to be confounded with the cellular tissue." Now, either it must be touched, or it must not be touched; but which course is to be followed does not appear from Dr. Knox's observations. But suppose the sheath may be touched, the phrase "*to such an extent*" is very indefinite. How much is to be removed? One quarter? one third? one half? or how much? For it must be evident that, unless some definite rule be followed, no two dissections will be alike. We may make the nerves larger or smaller, *ad libitum*, by removing the quarter or the half of the sheath. Further, Dr. Knox is greatly in error by supposing that "when we begin to open the sheaths the destruction of a great part of the nerves and ganglia must be inevitable"; for the whole of the fibro-cellular sheath may be entirely removed without the nervous structure being exposed, much less injured. The fibro-cellular sheath which surrounds the nerves serves two chief offices—one of protection, and the other as a support for the capillary network of blood vessels which supplies the nerves. But inter-

posed between this sheath and the nerve is a delicate membrane, with the free surface next to the nervous tubules. Now, the whole of the fibro-cellular sheath, including the minute bloodvessels, may be removed, and this membrane will remain, enclosing the nerve and protecting it from injury. Again, no one could commit a greater anatomical mistake than by saying that, if the sheath of the nerves be removed, "the nervous character is apt to disappear, and to be confounded with the cellular tissue." The truth is exactly the reverse; for with a small nerve the fibro-cellular sheath becomes confounded with the cellular tissue of the organ; and the only means by which a nerve can be kept distinct is by removing the sheath, and leaving it surrounded by the delicate membrane before alluded to. By this means I have traced branches which measured from the 500th to the 600th part of an inch in diameter: when smaller than this they become objects for the compound microscope. These errors of Dr. Knox are only equalled by his statement that the "grey matter is scraped away, and what appeared a single ganglion becomes a group of ganglions. Surely it is exceedingly easy to know when any grey matter has been scraped away from a ganglion, for, when such has been done, the ganglion loses the rounded perfect appearance which nature gives it, and is left with sharp and strongly-defined edges. Nor can the utmost art conceal the marks of the scalpel, or of the needle, which has been used to scrape away the grey matter. The delicate membrane which immediately invests the nerves also surrounds the ganglia, and equally allows the whole of the fibro-cellular sheath to be removed without any injury being done to them.

The remaining objection, "that the dissections of Scarpa, Walter, Lobstein, and all anatomists, might be objected to if the sheaths of nerves be once touched," is puerile in the extreme; for, however much we may venerate the names of these great and distinguished anatomists, the time is passed for being blinded by the weight of authority. The question at present is,—Ought the fibro-cellular sheath to be removed or not? and if it ought, can it be removed without injury to the nerve? Both these questions I unhesitatingly answer in the affirmative.

2. The small size of the nerves which accompany the arteries.

"I was not prepared for the fact, that few or none follow the vessels, that seem to me to be the result of his dissection."—*Literary Gazette*, May 16.

"I remarked to Mr. Beck, that the *scarcity of nerves* in his dissection, following the course of the arteries or vessels, surprised me."—*Medical Times*, Aug. 15.

By a mode of dissection which Dr. Knox appears to approve of, both the arteries and nerves are allowed to remain covered with much cellular tissue, which hangs loose in the preparation as flocculent matter. Small cords pass through this flocculent matter, and extend between the vessels and the nerves. These cords have sometimes been considered, and appear to be considered by Dr. Knox, as nerves passing to the vessels; whilst really they are vessels passing to the nerves, and ramifying in the fibro-cellular sheath. "Before the nerves were cleared from their neurilema, I frequently met with what appeared to be nervous branches distributed to the arteries; but in every instance I have been able, by the aid of the microscope, satisfactorily to ascertain that these were minute vessels passing from the artery to the nerve to ramify in its neurilema, and not branches of the nerve going to the artery".—*Philos. Trans.* for 1846, page 220.

By the same mode of dissection, the nerves are not followed so far in their course as I have dissected them. The larger nerves are seen to mix with the vessels, and it is concluded they follow the course of the arteries; but they only accompany them for a short way, and ultimately separate from them to be separately distributed to the organ. In my dissections the nerves have been traced beyond the point where they are in company with the arteries, and the vessels have been carefully removed to make the dissection of the nerves less complicated. "These nerves pass towards the uterus, and, mixing with the arteries of the part, go on in company with them for some part of their course; but as they approach the body of the organ they separate, and each pursue a separate distribution."—*Phil. Trans.*, p. 219.

Independently, however, of these nerves, which are distributed to the body of the organ, and whose larger trunks accompany the arteries for some way, there exists another set, which especially accompanies the vessels, and appears to be distributed to them. And whilst the nerves which supply the body of the organ "lose the plexiform character, and form a number of delicate branches, which pass on as distinct fine chords dividing and subdividing, but not uniting with each other,"—(*Phil. Trans.*, p. 219), the nerves accompanying the arteries "assume a plexiform arrangement round the vessels, and have the distinctive character of forming minute ganglia here and there. *Phil. Trans.*, p. 219.

3. The peculiar character of the pelvic plexus.

"I pointed out to Mr. Bowman (says Dr. Knox) that the plexus at the neck of the gravid uterus was unlike any nervous plexus found in the human body, or in the bodies of any of the lower animals, and remarked that I had never seen such a plexus before. It is an unknown and extraordinary form of plexus, perfectly anomalous, so that it is impossible to guess at its object."—*Literary Gazette*, May 15. "For he (Mr. Beck) observed to me that these were very peculiar, and 'unlike what occurred in other parts of the body'; perhaps I ought to have said that to me they did not seem to be plexuses at all."—*Medical Times*, August 15.

The plexus which is situated on the side of the vagina is so very peculiar, and "unlike what occurs in other parts of the body," that I have ventured to mark this peculiarity by giving it a distinct name—the pelvic plexus. To explain this fully would involve a lengthened description. The larger branches of the sympathetic nerve are well known to be composed of gelatinous and tubular nervous fibres. The tubular fibres are traced through the ganglia, and found to be derived equally from the motor and sensitive roots of the spinal nerves, whilst the gelatinous fibres are derived from the different sympathetic ganglia. Therefore, in nerves composed of these two kinds of fibres, there must be some point where they undergo the due mixture required for the different viscera to which they are distributed. And these points in the abdomen are at the semilunar ganglion, at the superior aortic plexus, and at the pelvic plexus. Thus the pelvic plexus is "unlike what occurs in other parts of the body," and its peculiarity is further shown by the following description:—

"The lower part of the lateral hypogastric plexus forms a continuous plexus with the pelvic plexus; and the only circumstance which marks the division between the two is the existence of small ganglia, and the junction of the branches from the sacral nerves. It appears, however, from the marked difference which exists in their constitution, necessary to make this distinction between the two plexuses. For whilst the lateral hypogastric plexus is a continuation of branches from the lower part of the superior aortic plexus, the pelvic plexus is a point where a new arrangement of the gelatinous and tubular nervous fibres occurs, previous to the branches being distributed to the bladder, vagina, and rectum. In this respect the pelvic plexus is analogous to the semilunar ganglion and to the lower part of the superior aortic plexus, from which it differs in the amount of nerves sent from it, and the large amounts of tubular fibres which these nerves contain."—*Phil. Trans.*, p. 232.

4. The condition of the long nerve which runs up by the side of the uterus to supply the portion immediately below the insertion of the fallopian tubes.

"You (Mr. B.) called my (Dr. K.) attention especially *to a remarkable long nerve* running down the front of the uterus, the course and presence of which rendered, in your opinion, the great portion of Dr. Lee's dissection doubtful. It sent off, you thought, no branches; it received, in your opinion, no communicating filamens throughout its length and course."

1. I remarked to you that this nerve was not of uniform strength, *but tapered*; but nerves which *taper* give off branches; *ergo*, this nerve must have given off branches originally, but no such are now to be seen; *ergo*, they must have been cut away.

2. I next remarked to you that it *tapered* unequally, that is, that it must have given off nervous filaments and received others. I showed you *two branches*, which must have been *cut across* during the dissection; the portions were still left attached to the pretended *long nerve*.

3. I soon after showed you two other branches which had been cut during the dissection; fancying that you were not so fully satisfied with them, I took the liberty of showing you that the nerve varied in thickness at these *additional points*, and that filaments lay beneath corresponding to the divided branches."—*Med. Times*, Aug. 15.

This nerve is figured in plate 14, No. 7.

1. That it tapers and gives off branches is very evident, as shown in the drawing; and that some of these branches have been divided, is also evident, as one of these divided branches, and one which Dr. Knox found, is represented in the plate at No. 8. Now, between this branch (No. 8) and the pelvic plexus, situated lower down, Dr. Knox also found a very delicate filament, which was not visible to the unassisted eye, and which the artist has not figured. It has never been concealed that some branches have been divided in the course of the dissection. But a few branches being divided does not invalidate the general truth of the dissection; more especially *when confirmed by another preparation, in which these divided branches do not occur.* The chief point at issue is not whether one or two nervous filaments distributed to the body of the uterus, and which measure about 1-200 of an inch in diameter, have been divided; but whether the small amount of nerves sent to the uterus be the true condition; or, whether, as stated in Dr. Lee's papers, the great nervous webs, "ganglia and plexuses," which cover the whole of the anterior and posterior surfaces of the uterus, "as high as the fundus," be the correct statement of the fact.

2. That it tapers unequally, *i.e.*, that it must have given off nervous filaments and received others. To the unassisted eye the nerve appears to taper unequally, but it will scarcely be believed that this unequal tapering depends upon the sheath being entirely removed in some parts, and only partially removed in others. That the thickened portion of the nerve, where Dr. Knox thinks it receives nervous filaments, does not depend upon any increase of nervous matter, but upon a portion of the sheath being left surrounding it. The course of this nerve is peculiar, and the nerve itself delicate, for which reasons I was not particular in removing the sheath from it in its entire course, lest, in doing so, it should receive any injury. But I remained content with showing the size of the branch at different points, and have to regret that the remaining sheath should have led Dr. Knox into error. Yet, had Dr. K. used a lens of sufficient power, the cause of this unequal tapering would have been readily recognised. The *two branches* spoken of have been noticed before.

3. "Two other branches which had been cut," and "that the nerve varied in thickness at these additional points." I am not aware of any more divided filaments on the long nerve than the two already mentioned. Nor is there any other varying in thickness except that caused by the sheath being either entirely or partially removed. Yet, lest I may be mistaken in the parts which Dr. Knox refers to, I shall be very glad to have it more specially pointed out in the drawings, or shown in the dissection.

"That filaments lay beneath corresponding to the divided branches" of nerve, is a great mistake of Dr. Knox. There are the ends of divided filaments lying beneath the nerve; but these filaments *do not correspond with the divided nervous filaments; nor are they nervous, but muscular, filaments.* It was to remove this doubt that I asked Dr. Knox to submit them to the compound microscope. But it appears he did not understand the motive of my request. Where the tissue of the uterus has been cut into, in dissecting the nerves,

the divided ends of fine cords of involuntary muscle are shown. It is these fine cords which Dr. Knox has mistaken for nerves, and which I would be unable to state the nature of, if I had not examined them with the compound microscope.

5. The occurrence of divided ends of supposed nerves in the tissues of the uterus.

"The tissues of the uterus had been but little opened into by Mr. Beck. When separated somewhat by myself numerous filaments might be seen which much experience convinced me were nerves. Mr. Beck's offer to submit any portion of these filaments to high microscopes I declined. For this there could be no occasion, with structures which I could make out, either with the unaided sight, or with the very feeble hand-glass you saw me use."—*Med. Times*, Aug. 15.

Upon taking up this long nerve with the forceps, I saw the ends of several branches proceeding from it which had been cut across. The cut ends were still hanging from the nerve. The corresponding cut ends lay in the tissue below, and could be raised up with the forceps, which I did. Upon looking up these cut ends I saw numerous filaments of nerves in the tissue below, and in the line of the vessels; and I told Mr. Bowman and Mr. Beck that I was satisfied they were nerves, and pretty large ones too; and that the nerves cut across led to plexuses of nerves amongst the plions (?) and vascular tissues of the uterus."—*Lit. Gazette*, May 16.

The divided ends hanging from the long nerve have been already mentioned: they are two in number. And, "upon taking up these cut ends, I saw (says Dr. K.) numerous filaments of nerves in the tissues below, and in the line of the vessels." Now, here Dr. Knox is again in error, for the filaments which he saw are not nervous filaments, but muscular. And, so far from the tissues having "been but little opened into by Mr. Beck," they have been cut into in several places, and in some to the depth of three fourths of an inch. Had Dr. K. submitted these filaments to the microscope he would have found that which appeared nerves "with the unaided sight, or with the very feeble hand-glass," were, in fact, small cords of the muscular tissue of the uterus. And, so far from there being "no occasion" for this test, there appears to have been every occasion. That these filaments "cut across led to plexuses amongst the tissues of the uterus" is evident, but the plexuses are muscular, and not nervous.

6. The large amount of nerves on the vagina when compared with those sent to the uterus.

Dr. Knox says—"I called Mr. Bowman's attention to the vast amount of nerves upon the upper part of the vagina, or where the uterus and vagina unite, which threw a doubt on my mind on the correctness of all the other parts of Mr. Beck's dissections, not disbelieving that what were shown me were really nerves, but believing that only a very small part of the nerves of the uterus were shown. The nerves of the vagina and those of the uterus form a striking counterpart to one another."—*Lit. Gazette*, May 16.

In making these observations Dr. Knox has forgot to separate the nerves distributed to an organ from a plexus which lies by the side of it. The pelvic plexus lying by the side of the vagina, and which forms "the vast amount of nerves upon the upper part of the vagina," sends large branches to the bladder, the erectile tissue at the anterior part of the vagina, and branches to the rectum; but a comparatively small quantity are distributed to the vagina. It might as well be said that the scaleni muscles are largely supplied with nerves because the brachial plexus lies between them, as that the vagina receives numerous nerves because the pelvic plexus lies by the side of it.

If I have not answered all the objections made by Dr. Knox, I hope it will not be said that this letter "does not contain the whole truth," for I have answered those objections which appear to me the most important, and, should it be considered requisite to notice the remainder, I am ready to do so. As, in many parts of this letter, my opinion stands in direct opposition to that of Dr. Knox, I can only appeal to another examination of the preparations in order to decide who is correct. I cannot quit this part of the subject without expressing my regrets on two points of Dr. Knox's letter—viz., that he should have considered it necessary to insinuate that I left the room during his visit because I thought I had lost Mr. Bowman's "support on a most important point." Dr. Knox has thought right to assign this motive for my temporary absence, which was caused by professional business, without having made inquiry into the real cause; and in doing so he, I think, has shown a spirit which is neither friendly nor candid. If, without previous acquaintance, he attributes a motive personally disparaging towards me, to a professional act of mine, without taking means, which were at hand, to ascertain the truth, how can I expect of him candour or fair examination when more important matters are concerned? Dr. Knox next repeats the insinuation that I was instigated by some members of the Physiological Committee to commence the inquiry "for the purpose of injuring Dr. Lee's reputation." He avers that he entertains this belief. Yet I, who know the facts, give it my most most unqualified contradiction. He came to my house with this impression on his mind. Is it, then, to be considered that he came as an impartial observer to ascertain the truth? He, moreover, seeks to implicate the names of gentlemen of high character. Surely the scientific question is one which would bear being examined without the admixture of such topics in the inquiry—a course which can have no other effect than that of producing irritation, and, probably, shutting the real question from view. To say the least, such matter is irrelevant when questions of fact in anatomy are alone concerned.

I remain, Sir, your obedient servant,

T. SNOW BECK.

AFFECTION OF THE BRAIN FROM EXCESSIVE HEAT CAUSING TEMPORARY INSANITY.

By THOMAS SMITH, Esq. King's College Hospital.

CASE 1. On Sunday last, August 2nd about 2 p.m., I accidentally called upon a medical friend of mine, who had gone into the country, and was requested by his lady to see his apprentice, a young gentleman aged 18, as he had two or three minutes before my arrival been taken very ill. On entering the bed room, I found him leaning on the back of a chair, burying his head and face between his arms, on speaking to him, I could obtain no answer; and on my attempting to hold up his head, he became very violent, struggling to get away from me, and attempting to bite me. His head, which is very large, was hot, the pupils moderately dilated, the pulse about 90. With great difficulty I laid him on the bed, and bound his arms and legs together with towels; whilst doing this he was most furious, he bit his own hands, and anything he could lay hold of, such as the pillow, or the mattress; tore off the bonds from his wrists by his teeth, and got off the bed once or twice. Having so secured him that he could not well get away from me, I poured some jugfuls of cold water, from a height upon his head. This had an instantaneous effect, he became sensible, knew me, and complained of my wetting him so much. In a few minutes however, his eyes became fixed, he did not answer me when I spoke to him, and he appeared to be relapsing into a state of insensibility. I applied the cold water again vigorously, which had the effect of restoring perfect consciousness, he complained of pain and heaviness in his head, which was hot. His face was flushed, pulse full and firm, about 90. I immediately took ten ounces of blood from him, whilst sitting up in bed; this measure gave him marked relief, the uneasy sensation in his head became less, and the pulse became fuller than it was before. He talked cheerfully to me, and became quite quiet. I gave him Calomel gr v. to be followed by ℥ss. mag. sulph.; applied cold to the head, and desired that he might be kept perfectly quiet.

10 p.m. On calling again, I found him a good deal excited; he talked rather wildly, and was very obstinate. I learnt, that since the bleeding he had been so well, that he got out bed and put some his clothes on, asked for a book to read and when the medicine began to disturb his bowels, he walked out into a passage to the watercloset; he had taken some tea, and was very well, until late in the evening. As he had had no sleep, I measured out twenty-two drops of tinct Opii—and with great difficulty prevailed upon him to take it. I stayed by his bed-side to watch the effect. It was decidedly unfavourable, for he became more excited, complaining of a feeling as though he was tipsy. Hoping that the laudanum might quiet him, I did nothing else, but he soon became very nearly as bad as when I first saw him; he got out of bed; threw off the cold rags from his head; and became very unmanageable; sitting up in his bed, staring wildly, and pointing with his finger, at imaginary objects. I again applied cold water in large quantities to the head, with good effect. He became more calm, called me by my name, and from that time remained more quiet, although he was not perfectly sensible until past twelve. He had not passed any water for eight or ten hours.

Monday August 3. He slept after I had left him. Feels pretty comfortable this morning, complains of some pain in the head, is quite conscious, pulse 60 regular and firm. To take a small dose of mag. sulph. during the day, and to be kept quite quiet.

Tue day.—My friend when he returned from the country, ordered him some tartar emetic which had made him rather sick. He sat up to day, and eat some meat. This evening he was very much excited again, but he is now sensible. I advised five grains of calomel to be given, and perfect quiet to be observed.

Wednesday. Is much better, has had no retur of the symptoms, bowels are well opened, he is sitting up in an easy chair, the chief thing he complains of is weakness.

Sunday Aug 9th.—This young gentleman is quite well, and is now able to attend to his duties—

The following is the history I obtained: —On the Saturday previous to my seeing him, which day will be remembered as being the hottest day this summer; he went into the city, and ran very fast; being excessively hot, he took one small glass of ale at a friend's house, and then set off to return. He felt the heat very much. Before he had gone very far, the violent thunder storm commenced suddenly. He placed himself under a doorway, and from that moment, he lost recollection, and how he got home he cannot tell. When he arrived, the people in the house noticed him to be very peculiar in his manner; he threw a footstool at the wife of my friend, and did other eccentricities. He was put on the bed, and then became violent and excited. My friend saw him, and prescribed tartar emetic, and a purgative. He seemed better afterwards. Next morning he was very unwell, he had had no sleep during the night and complained of his head, he ate some dinner in the middle of the day, and soon afterwards fell into the state in which I saw him.

For the notes of the next case, I am indebted to my friend and late fellow student. Mr. Peter Duncan, with whom I saw the patient once or twice, and to whose discrimination and judgment, was due the proper diagnosis and success of the affection, as it had been mistaken the chorea by one gentlemen before Mr. Duncan took it into his hands.—

CASE 2.

A young healthy lad aged 15, remained in a public tepid bath during five hours on Sunday, the 26th of July. Occasionally he dived off a considerable elevation, and on arising to the surface, was exposed to the rays of the sun, whose effects were enhanced by a skylight. On leaving the bath, he complained of great lassitude and pain in the upper part of his head, he reached home with difficulty, and passed a sleepless night.—

Monday. He walked up Regent street to the

Park, and was exposed to the sun for several hours, complaining much of headache, he went to bathe, but as he was about to undress, he became delirious. His mother thinking him unwell, took him to a surgeon, who gave him a cathartic and advised quietude.

Tuesday. After a restless night he went out, but on account of his mischievous propensities was obliged to be sent home. Slight restraint rendered him quite maniacal, attacking those around him, and breaking whatever came in his way. His medical adviser was kind enough to send him to me as a case worthy of notice. I saw him on Wednesday evening, he seemed to sit uneasily, his eyes constantly wandered; when anything near struck his view, it was seized and if in his power destroyed, suddenly he would drop his head and appear sleepy, a moment after, jumping up he would commit some unaccountable absurdity. He appeared to have a great dislike to speak or to be in any way disturbed. His special senses were acute—eyes suffused, pupils dilated, and features contracted; tongue red and tremulous—skin hot, pulse 120—tolerably strong no cough or abnormal sound in the chest bowels not opened since Saturday—urine scanty,—highly coloured. Ordered head to be shaved and kept high. Diet of the simplest kind.

R. Hyd. chloridi, pul. ipecac. aa gr. v. statim, sumend. et cras mane rep.

Thursday—Passed a sleepless night and is in much the same state. Bowels open, Pulse 120. Urine still scanty.

R, Ant. pot. tart gr. iss.; Tinc opii. m. v. aquæ ℥j - 3 tis horis.

After two doses he became calmer, the third induced sleep

Friday.—Has slept five hours, is more rational and quiet. Skin perspiring, urine much increased in quantity, bowels open, pulse 90. To go on with his medicine and to have beef tea.—His delirium left him in the afternoon, and he fell into a sound sleep, which lasted till early on Saturday morning.

Saturday. Awoke much refreshed, intellect still slightly confused, recollects none of the incidents of the past week, eyes natural, pulse 72 — Pupils slightly contracted, pain in head gone, to have a mutton chop, omit one grain of the tartar emetic.

Sunday. Has slept well, wishes to get up as he is free from pain, is quite rational, cannot believe that a week has elapsed since he has been taken ill, discontinues all medicine.

Monday. Convalescent.

My object in publishing these cases, is to put on record two cases of an affection which is generally rare in this country; but I should think many such cases must have fallen under the notice of the profession this summer, which has been remarkable for the extreme and constant heat. The two cases will be found similar in several respects; although the excitement in the first case amounted to a state of furious mania, whilst in Mr. Duncan's case, the symptoms at times were those of a person labouring under idiotcy; in fact, in both cases the symptoms indicated an excited sensibility of the brain, and the remedies used in both cases, had a tendency to tranquillize the brain. Affusion of cold in the first case, applied frequently and vigorously, was the successful remedy; in the second case, tartar emetic and opium, which every well-informed practitioner now knows to be so useful, in most cases of excited sensibility of the nervous system, overcame the symptoms, and I particularly wish to draw attention to the large dose of tartar emetic which the patient was able to bear without vomiting—sleep having been produced after three doses, and the delirium having ceased after its administration —shewed its great utility in the present case.

The Academy of Sciences of Toulouse has proposed as a prize subject for their gold medal, "The nature and true seat of lead colic; the signs by which it may be diagnosed from other intestinal affections; the curative indications which it presents, and the treatment likely to fulfil them.

HOSPITAL REPORTS.

MEDICAL TIMES PRIZE REPORTS.

THIRD SERIES.

Reported by WILLIAM ANDERSON, Esq., Student at St. George's Hospital.

MEDICAL CASES.

SUBJECT—HYSTERIA.

CASE 1.—HYSTERIA.—Charlotte Atkins, aged twenty-five. Married.

Admitted May 21, 1845. Under Dr. Nairne.

Skin cool; tongue red and glazed; pulse 90, weak; urine free, pale-coloured, and voided in considerable quantities. Appetite bad, sometimes ravenous; catamenia regular; bowels irregular, sometimes confined, at others relaxed.

Complains of violent pain in the right side; shooting between the shoulders; shortness of breath; palpitation of the heart; has a dry, hacking cough, without expectoration; feels sick and faint after eating; is troubled with flatulence, giddiness, and heaviness of head, with occasional dimness of sight; there is pain in the left lumbar region, increased by pressure; she sleeps pretty well, but is low-spirited.

Says that she had a fall seven years ago, and "hurt herself over the left kidney"; for which she had, according to her own account, twenty-four blisters, and was only partially relieved; the pain is worse when the catemenia are present; her head and eyes have been affected for the last two or three years. To have broth diet.

℞. Haust. cinchonæ, ℥iss.

Acid. sulph. dil. m. x. bis die.

22. Pulse 108, small and weak. She *lies with* her legs drawn up, and complains of great pain in the abdomen, which is tympanitic; pain increased on *touching* the abdomen, but when her attention is drawn away she can bear pressure, and even allow the bowels to be squeezed in the hand, without showing any sign of pain; urine copious and pale. She is troubled with acid eructations. To have fish diet

℞. Pil. colocynth c. hyoscyami, gr. x. hac nocte.
Liquor calcis, mist. camphoræ, aa ℥ iv. ter die.

23. Symptoms much relieved; has no acid eructation; less flatulence; and no pain in abdomen.

24. Tongue clean; less red; less sickness; bowels open.

Rep. pil. alt. noct.

27. Better; less acidity of stomach and rising in the throat; still pain between the shoulders; tongue clean.

29. Appetite better; tongue clean; bowels open: still some heaviness in head and dimness of sight; feels very weak. Ordinary diet.

30. Still pain in the left side; sickness. Catap. sinapis, lat. sinist.

31. Pain relieved; no sickness; tongue clean; bowels very open.

June 3. Appetite better; no sickness; tongue clean; feels stronger. Discharged cured.

CASE 2.—PERITONITIS.—Ann Draper, aged fourteen. Laundress, single.

Transferred from Mr. Tatum to Dr. Nairne, May 15, 1845.

Admitted, April 23, for a severe strain of the left wrist; followed by synovial inflammation and ulceration of the cartilages.

At the present time the pulse is 120; skin warm and moist; bowels open from medicine; urine natural; tongue white in centre, moist at edges; papillæ prominent; catamenia have not yet appeared.

Great pain in the abdomen, increased by pressure; sickness and vomiting of bright green fluid this morning. These symptoms began in the night of the 12th instant, and were preceded by a rigor and pain in the head and legs.

The face is now flushed; countenance pinched; an eruption of red patches has appeared on the skin of the neck and chest, but has now disappeared; there is no sore throat. Fever diet.

℞. Haust. salin. efferv. ℥iss. 6tis horis.

16. More fever to-day; tongue coated and becoming dry; lips dry; eyes dull; more pain and tenderness of abdomen; pulse 120, very weak; bowels relaxed; complains of cough; and there is large crepitation heard between the scapulæ.

℞. Hyd. chloridi gr. ij. 6tis horis.

Has had a mustard poultice on, which for the time eased the pain in the abdomen. Rep. cat. sinapis.

17. Tongue rather cleaner and moist; pulse 108, stronger; complains of pain and great tenderness over the whole abdomen on pressure; bowels very much relaxed; motions watery and dark-coloured; has vomited three times this morning the same bright green-coloured fluid; there is great prostration of strength; she had an injection of starch and opium this morning, and turpentine fomentations to the abdomen, since which the bowels have not been so open; coughs more. Hirudines viij; abd. catap. Anthemidis. Rep. Haust. salin. et Hyd. chlorid.

18. Rather better; can bear more pressure on the abdomen; face not so much flushed; tongue cleaner. Pulse 108. Has vomited the green matter twice again; still complains of pain in the right hypochondrium, and much tenderness on pressure. Bowels opened only once since morning. Beef tea. Emp. Lyttæ. lat. abd. dext. Rep. Haust. salin. et Hyd. chlorid.

℞. Olei ricini, ℥ss. cras. si opus sit.

19. Bowels opened once since the oil; pain in abdomen not quite so violent; tongue cleaner; face flushes much at times; has vomited constantly the same matter as before. Soda-water.

20. Has been sick again this morning; pulse 120; bowels opened three times; motions lumpy; complains of a nasty taste in the mouth, and is very thirsty; tongue clean and moist; she lies on her back with her knees drawn up, which she says relieves the pain in the abdomen. There is still much tenderness over greater part of the abdomen on pressure.

℞. Haust. sennæ ℥iss. cras.

21. Face not so much flushed; still has constant vomiting; bowels very loose, motions thin; coughs; is very thirsty; tongue cleaner; pulse 108, rather firmer.

℞. Hydrarg. chloridi gr. iij. Opii gr. ss. ter die.

22. A little better; bowels less open; still sick, throwing up the same green matter; bears pressure on the abdomen better. To have an egg.

℞. Haust. sennæ, ℥iss. cras.

23. Weaker; still vomiting the same green matter; pulse 120; coughs very much; expectorates much; bowels open; abdomen tympanitic. Rep. pil. et Haust. salin. Vini rubri, ℥ss. ex aq.

24. Says she feels better; abdomen softer; bowels open, motions somewhat lumpy; pulse 108, soft; tongue white; still vomits.

25. The vomiting has ceased; there is a great deal of expectoration mixed with blood; bowels open; motions more solid. Arrow-root. Vin. rub. ℥iv.

26. Pulse 120; a little stronger; slept better; more cough and expectoration. Fish diet.

27. More sickness; coughs much; feels better; less pain in the abdomen; pulse 132, soft; crepitation at back part of both lungs.

28. Countenance much improved, has lost the flush; less pain on pressure over the abdomen; not so much cough; slight vomiting of half-digested food; pulse 120; bowels open; appetite better.

31. Not so well; more pain on pressure at umbilicus; vomiting continues; flushes at times; pulse 136, not so full; tongue brown; bowels very open; mouth sore; still expectorates mucus streaked with blood; no appetite. Cat. sinapis, epigast. Omit pil. To have arrow-root.

June 1. Much the same. Removed at the request of her friends.

CASE 3.—HYSTERIA.—Mary Ann Blake, aged nineteen, servant of all work. Admitted May 19, 1845, under Dr. Nairne. Skin warm; tongue moist and white; bowels confined; has difficulty at times in making water, which is clear, pale, and copious; catamenia regular; pulse 108; has thirst, and complains of pain in the side and pit of the stomach, and has shortness of breath on going up stairs; appetite bad. Ordinary diet. Has globus hystericus.

℞. Ext. colocynth, C. Ext. Hyoscyami, aa gr. v Pil. Galbani C. gr. v., omni nocte.

Haust. sennæ, ℥ iss cras, et rep. omn. alt man.

22. Much the same. P.

24. Catamenia adsunt. To leave off the pills for a few days.

27. Catamenia still present; has headache, and complains of beating at the head. Rep. pil.

℞ Haust. cinchonæ, ℥iss bis die.

29. Complains of pain in both sides of the thorax. Catap. sinapis. lateri utrique.

30. Still pain in sides. Rep. cat. sinapis.

31. Pain much relieved by poultice. P.

June 3. Feels better; appetite improved; tongue clean; wishes to go out. Dismissed cured.

Case 4.—Hysteria.—Sarah Porter, aged twenty-one, servant of all work. Admitted May 21, 1845, under Dr. Nairne. Skin cool; tongue clean and moist; complexion muddy; has pain in head and pit of the stomach; beating of the heart and globus hystericus; pulse 96. Catamenia per quatuor menses desunt. Ordinary diet.

℞. Inf. rosæ C. ℥iss. Magnes. sulph., ʒi. Acid. sulph. dil, *m.* x. ter die.

Pil aloes C. gr. x. h.n.

22. Bowels confined. H. sennæ ℥iss stat. Rep. pil. o.n.

24. Catamenia have appeared; feels better. Omit. med.

26. Catamenia still present; pulse weak.

℞ Mist. Ferri. C. ℥i. ter die.

29. Much the same. P.

July 3. Better. P.

7. More colour in face; feels better; sounds of heart loud and sharp, and a slight murmur heard with the first sound.

10. Getting stronger; tongue quite clean. Rep. mist. Ferri. C. ℥iss ter die.

12. Better; has more colour in face. P.

14. Better; medicine makes her sick. Omit. med.

17. Left cured.

Case 5.—Hysteria.—Eliza Simmonds, aged seventeen. Admitted May 21, 1845, under Dr. Nairne. Skin cold; tongue clean and moist; appetite good; complains of thirst; bowels open; sleeps well; catamenia regular; urine light-coloured and copious; complains of great weakness, with loss of power in the leg and arm of right side, and inability to walk without crutches; has a continual shaking, which came on about a year ago; has spasmodic contraction of the muscles about the left side of mouth, and complains of occasional shooting pains in the head; can stand on left leg. Says she had a fall a year ago and hurt her back, and has had issues in the back without relief. Ordinary diet.

℞. Haust. cinchonæ, ℥iss. Spir. ammon. aromat. *m.* xx. ter die.

℞. Pil. galbanii, C. Ext. colocynth. C. aa gr. v. O. N.

22. Back examined; can bear percussion on any part of it; spine perfectly straight; pulse weak; seems to have a want of will rather than of power, to get up and help the nurse and not remain idle.

24. Says she feels stronger, and does not shake so much. Pulse weak. P.

27. Much the same; has no want of power, being able to grasp things strongly with her right hand to save herself from falling; she can also stand upon the right leg when her attention is drawn off.

29. Feels stronger; bowels very open. Rep. pil hac nocte tantum.

31. Just the same. P.

June 3. No improvement; tongue clean; bowels open.

℞. Liq. calcis ʒxi. Tinct. Assafœtidæ, ʒi. ter die.

Rep. pil. o.n.

7. Much the same, with the exception of the face not being quite so much distorted.

12. Just the same; no improvement.

17. Feels heated, otherwise just the same. Balneum.

24. Just the same.

25. To go out.

Case 6.—Anasarca and Hemiplegia.—Laura Schmidt, aged thirty-two, married. Admitted April 29, 1845. Under Dr. Nairne. Tongue slightly furred, moist; pulse 120; appetite good; bowels open; catamenia regular; urine scanty and high-coloured, acid; there is great œdema of the lower extremities and swelling of the body. Complains of cough, shortness of breath, and has lost flesh for the last three months; has no violent pain; was confined last month. She is subject to a winter cough, and has palpitation of the heart.

The chest expands but very little; there is dulness under right scapula on percussion, and some crepitation at the lower part, in front; the respiration on both sides is coarse, and bronchial; dry rhonchus heard on both sides. During the last six months of pregnancy, she had general anasarca to a great extent, which all disappeared after delivery; there was considerable hemorrhage at the time of delivery; she did not suckle longer than a week.

There is increased impulse in the action of the heart, with an indistinct murmur over the aortic valves in the second sound. There appears to be considerable dilatation of this organ. Ordinary diet.

℞. Potassæ nitrat. gr. v. Spir. æther. nit., ʒi. Vin. ipecac. *m.* xx. Haust. pimentæ ʒx. ter die.

℞. Haust. morphia o. n.

30. Cough and expectoration much the same; countenance livid; copious deposit of lithates in the urine, first becoming clear, then thick again by heat.

℞. Antimon. pot. tart., gr. $\frac{1}{4}$. Potass. nitrat., gr. v. Spir. æther. nit., ʒi. Aq. menthæ virid., ʒix.

Emp. lyttæ int. scap. To have broth diet.

Olei ricini ℥ ss. stat. Omit. haust. morphiæ.

May 1. Had a fit at half-past three P.M. yesterday as she was going to the water-closet; she then fell on her face, and became perfectly insensible, with convulsions of the muscles on the right side of the face; there is now nearly total paralysis of the whole right side, and partial loss of sensation. The lips became blue during the fit, which was followed by frothing at the mouth and a deep sleep, which lasted some hours.

2. Bowels opened three or four times since the fit; œdema of legs and body somewhat diminished; pulse 120, very weak; respiration laborious; does not seem to suffer much pain, but is still nearly in a state of insensibility, and answers questions very indistinctly and with difficulty; urine very slightly albuminous and acid.

Rep. mist. sine antimon.

Spir. vini gallici, ℥ij.

3. She can move the finger and foot of right side a little, but complains of pain in the head; respiration still laboured, and much obstructed by mucus; answers questions slowly and imperfectly; pulse 120; right hand œdematous; eyes open, pupils dilated; bowels not open.

℞. Olei ricini, ʒ iij. statim.

5. Rather more sensible, and says she feels better; more motion of the right hand and arm, and some motion in the right leg; articulation improved; bowels not open yesterday; had some castor oil this morning, which has operated.

6. More motion in the arm; swellings less; bowels open.

8. Rather more strength in the right side; can it up better in bed, and feels better; speech improved, and more motion in the arm, which is swollen and œdematous; the face is drawn to the left side a little; urine scanty; bowels confined. Beef tea.

℞. Pulv. jalapæ C., ʒ ss., o. m.

10. Says she does not feel so well; her respiration is jerking and more difficult; lips and face more livid in colour; bowels opened three times since the powder; extremities cold.

12. Respiration very quick and laboured; lips more blue; urine scanty and high-coloured. Omit. pulv.

℞. Pil. digitalis C., gr. v., bis. die.

13. Skin over left hip has become red and tender from lying on it; left arm more swollen.

15. Respiration difficult; loud crepitation to be heard on both sides of the chest; pulse very weak; urine rather increased in quantity, and clearer. Spir. vini gallici, ℥iv. Light pudding.

17. Not so well, getting weaker, and makes less water, which is thick and high-coloured; respiration more laboured; lips more livid; pulse small and weak.

℞. Spir. æther. sulphur. c., *m.* xx. Spir. æther. nit., ʒi. Oxymel. scillæ, ʒi. Mist. camphoræ, ʒ ss., 6tis horis.

℞. Pil. colocynth C. hyoscyami, gr. x., o.a.n.

Omit. pil. digital. C.

20. Getting weaker; pulse 120; respiration difficult; coughs more; bowels open; great œdema of right arm and hand still.

22. More conscious, but passes her motions and urine under her; makes less water. Rep. mist. et pil.

24. Much the same; takes her nourishment; coughs, but has no power to expectorate.

27. Makes very little water, still passes her motions under her; bowels regular; appetite good; less swelling of arms and legs; still laborious breathing. Rep. mist.; Pil. digitalis C, gr. v., bis die.

29. Stronger; turns herself in bed; makes more water; face less swollen; appears now quite childish. Rep. pil.

℞. Spir. æther. nit., ʒi. Tinct. lyttæ, *m.* xxx. Spir. æther. s. c., *m.* xx. Mist. camphoræ, ʒx., ter die.

June 3. Makes more water, but still passes it unconsciously; face very purple; bowels confined.

℞. Pil. colocynth. C. hyoscyamo, gr. v., p.n.

5. Has fallen away much in the face and arms; has less cough; urine loaded with lithates.

7. Makes less water; gains strength; pulse 120; tongue clean.

10. Still very much swollen; more sensible; getting thinner; bowels confined. Rep. pil. col. C. hyoscy.

12. Sits up in bed; face less swollen; still considerable œdema of the legs; makes more water; no albumen in it, and it is very light-coloured.

14. Face less livid; the heart is heard over a larger surface; bowels open.

17. Legs less swollen; makes more water.

18. No albumen in urine; bowels very open; she is more sensible, and looks better.

24. Makes more water, motions still passed unconsciously.

26. Mouth sore. Omit. pil. digit. C.

28. Thinner; face more contracted.

July 3. Feels much better, bowels not open. Haust. sennæ, ℥iss. cras mane.

14. Urine still runs from her. She can now use her right arm a little.

17. Is troubled with cough. Haust. cetacei ℥iss. ter die loco mist.

19. Very drowsy; cough easier; large crepitation heard over both sides of chest.

22. More lively in manner, but the cough is very troublesome; legs much swollen.

26. Cough better; manner is childish.

29. Countenance more livid, legs more swollen, erythematous blush on each calf. Resumat usum mist. Maii 29th.

Aug. 2. Much the same. P.

4. Constant hacking cough; sleeps badly at night. Haust. morphiæ. o.n.

7. Abdomen more swollen; left arm œdematous; more childish in manner; urine albuminous.

13. More swollen; has great difficulty of breathing.

16. Rather more collected in manner.

19. Much the same.

23. No difference; sleeps from night draught.

26. Sleeps well at night. Omit. mist.

Sept. 2. Sank gradually, and died at a quarter to eight A.M.

SECTIO CADAVERIS.

Cranium. A large quantity of fluid was found in the sub-arachnoid tissue, and the visceral layer of the arachnoid was thickened and opaque, whilst the free surface of the parietal arachnoid, corresponding to the upper part of both hemispheres, and to the tentorium cerebelli on the right side, was covered over by a very thin, delicate membrane of a slightly yellowish colour, and containing in its tissue numerous minute points of blood, disposed in an arborescent form, and making it at first sight

appear as if the vessels beneath the parietal arachnoid were very minutely injected; but the whole was easily peeled off in the shape of thin films: these appearances were more marked towards the posterior than towards the anterior part of the skull. The brain itself was of a pinkish colour generally, but the puncta of blood in the centrum ovale of Vieussens were large and numerous. The ventricles were slightly dilated, and contained some clear serum. In the central part of the left corpus striatum was a yellow spot of the size of a sixpence, the surrounding part of the nervous tissue being of its natural colour; both the yellow spot and the parts in the neighbourhood were softer than any other part of the brain. The other parts of the brain and its vessels were healthy.

Thorax. A large quantity of fluid in the cavities of both pleuræ; more, however, in the left than in the right, which was partially obliterated by old adhesions. The right lung was throughout the greater part of its extent loaded with very large quantities of red frothy serum, and the left lung was somewhat compressed, but not œdematous; small quantity of clear fluid in the pericardium. Heart enormously enlarged by dilatation of its cavities, with atrophy of its walls; all the cavities were distended, but especially the right, with large, firm, and dark coagula of blood, which also extended into the large vessels connected with the heart; left auriculo-ventricular opening slightly contracted by thickening of the mitral valve, the other valves healthy.

Abdomen. The peritoneal cavity contained a very large quantity of clear straw-coloured serum, peritoneal covering of the liver opaque and slightly thickened. Liver itself somewhat contracted, and with round margins. Venous hepatic congestion of the second degree existed to a great extent. Both kidneys were of their natural size; the capsules adhered more firmly than natural, but the surfaces of the organs were perfectly smooth; spleen hard, small, and congested; superficial ulceration of the cervix uteri, with congestion of the upper part of the vagina. Structure of the uterus itself soft and easily torn, and its mucous coat was congested and covered with a foul secretion. The ovaria presented nothing remarkable.

REVIEWS.

The Sanative Influence of Climate. By Sir JAMES CLARK, Bart., M.D., F.R.S., Physician in Ordinary to the Queen and to the Prince Albert. 4th edition, 8vo., pp. 412. London, 1846.

Perhaps no man of the present day could be found better qualified for writing a comprehensive and complete work on climate than Sir James Clark. For the due accomplishment of a task like this, various prerequisites are needed. Foremost of these is a sound knowledge of practical medicine, and of the various sciences auxiliary to it. Without such, it is obvious that the judgment of the observer would be liable to be imposed upon. The characters and causes of disease, and the particular and general indications of its treatment—in other words, rational pathology and therapeutics—are the first qualifications called for. To these should be added, at least, competent knowledge of chemistry, geology; natural philosophy, with all its relations to atmospheric, terrestrial, marine, and fluvial phenomena; botany, geography, &c. These things, theoretically understood, should afterwards be confirmed and made positive by actual experience in the particular scenes peculiar to their application. To know the several facts in theory is important enough; but to know them in practical detail is much more so. Only thus known can they be scientifically and skilfully rendered to us as items of instruction. To say that Sir James Clark has answered the chief expectations that would be formed of him on the subject of that before us is, in other words, to say that this selfsame work has legitimately reached its fourth edition. Were none other proof present, we could easily refer to this as demonstration enough, considering the general character of the work, that it had not realized its rapid and extensive demand without having fully deserved it. To this professional and popular opinion we have great pleasure in adding our own deliberate testimony. We have no hesitation in declaring our belief, that the work of Sir James Clark on climate is the best extant on the subject which it comprehends.

To enter into a worthy analysis of it would not consist with the space we can afford to devote to its consideration; we must therefore be content with giving its leading features.

After a judicious and generalizing introduction, somewhat pithily illustrative of what is to follow, we come upon the text proper at once. *Part the First* comprises, in light but accurate detail, the leading characteristics of dyspepsia, which our author divides into the gastritic, irritable or nervous, and atonic. To these succeed observations on tuberculous cachexia, pulmonary consumption, ventilation and unhealthy residences, diseases of the larynx, trachea and bronchi, asthma in its several varieties, gout, chronic rheumatism, delicacy in childhood and youth, climacteric disease, diseases of warm climates, and convalescence. Without pausing to comment on any, it is bare justice for us to say that all of these particulars are treated with a just judgment and a delicate discrimination.

Part the Second, after some admirable general directions for invalids, preparatory and subsequently to change of residence, is constituted of remarks on the different climates and places that are valuable as resorts for invalids, the world over. There are no less than fifty-two select places treated of in reference to their physical geography, their general salubrity, and their adaptability to mitigating or curing different forms of disease. This part constitutes the leading feature of the work, and it is executed with a skill and judgment that leave little or no room for criticism to suggest improvement. The work is terminated by an appendix concerning the climate of the southern hemisphere, mineral waters, natural and artificial; and the meteorology of the different places previously treated of. The last two, as matters of reference, cannot fail to be of considerable advantage to those who may need to consult them. The style in which the work is written is excellent. It is elaborate enough for the professional reader, and yet sufficiently simple and explicit to constitute a travelling companion to the invalid. To both we commend it, in the unequivocal belief that it is the best book in any language on the subject it embraces.

The Elements of Natural Sciences. By Prof. DUMERIL, of the Institute. Paris: 5th edit. 2 vols. 8vo. Pp. 326 and 354.

This curious work appeared for the first time in 1802. The plan was conceived by Napoleon, and executed by his orders. Professor Dumeril so exactly embodied in his work the ideas of the First Consul that the book was at once adopted by the University, and has since enjoyed the merited honours of five successive editions. Conciseness was the chief object of the author, and he certainly has succeeded in attaining it, without injury to his subject. The first volume contains a complete treatise of chemistry, geology, and botany; but it is in the second that the natural tendencies of the author are chiefly discernible: it contains a complete history of organized nature. The chapter on Insects is one of the most curious in the book; M. Duméril has spent sixty years in their study, and nothing has escaped him, from the habits of the aquatic spider to the murderous tastes of the hydrophilæ. The fishes and birds also afford M. Duméril the opportunity of the most interesting details. The learned author excels in graphic description, and in the happy art of casting a lively interest over a subject which the multiplicity of scientific divisions seems to have endowed with didactic aridity. The book is full of interest, every line contains information; and its compact form makes it invaluable to those who are desirous of obtaining in a short time a complete insight into the details of the accessory sciences.

OBITUARY.—We regret to have to record the death of George Langstaff, Esq., which took place at his residence on the 10th inst.

TO CORRESPONDENTS.

Several letters have been received, commenting in strong terms on the Hounslow case of flogging, for which we have no room. The interest on this subject is rather increasing than diminishing, but we have endeavoured ourselves to do it justice.

The paper by A Licentiate of the Hall *is under consideration.*

The cases by Mr. Smith, house-surgeon to King's College Hospital, have been received.

Josephus *on Cholera has been received.*

Dr. Walker's *strictures (from Ludlow), in reply to a certain Dr. Bell, we are reluctantly compelled to decline. We cannot* constantly *consent to be a court of appeal—after the erroneous or unjust decisions of the lower courts, we had nearly said! The paper may be inserted as an advertisement.*

Dr. Orpen, *who writes a long article complaining that the Editor of the* Lancet *lends himself a willing tool to private professional malice, is requested to accept the above answer also.*

M. D.—*It was not Mr. Guthrie, but Mr. Wakley, who published without provocation a confidential paper by Mr. Lawrence, after keeping it in his possession twenty-five years with a view to some such purpose.*

A Subscriber.—1. *The registration has died stillborn. It is withdrawn as we prophesied.—2. Mr. Guthrie.*

A St. George's Student *will probably find what he asks for very shortly in the "Medical Times."*

Mr. Yates. *—Midwives in England are not required by law to prove any qualification or to possess any diploma.*

For Mr. Webb's vigorous letter on the Registration Bill we have, unfortunately, no room.

Mr. Self *may depend on it that we shall not long overlook the* assurance *offices* modestly *demanding professional toil gratis.*

Mr. A., *New Ross, is informed that we have no time for private replies to scientific questions. His question is, besides, one on which we have no information.*

The National Institute.—*Several letters have reached us on this important project. We shall give some, and enter fully into the matter ourselves in our next number.*

A Subscriber, *perhaps, wishes to rescue one of his communications from the oblivion to which he has voluntarily consigned it by publication in the pages of the journal named. Our worthy correspondent, we are sure, will, on second consideration, admit that pending the law proceedings there is no course open to us except that we have taken. The paragraph was an oversight.*

Mr. Alfred Markwick *shall be communicated with privately. His second paper has been received.*

A Junior Practitioner *should attend the practice of the* London Cutaneous Institution, *taking as his text-book the valuable lectures of* Mr. Startin, *at present in course of publication in this journal.* A Junior Practitioner *will find the subject, hitherto confessedly a very intricate one, rendered extremely simple by* Mr. Startin's *mode of classification, and by his scientific application of a few general principles.*

Mr. P.'s *letter is an advertisement.*

The paper headed Pulpy Wilson *cannot be inserted.*

THE MEDICAL TIMES.

SATURDAY, AUGUST 29, 1846.

"Aude aliquid brevibus gyaris et carcere dignum,
Si vis esse aliquid."—JUVENAL.

"There is another feature in the trial which has given so painful a celebrity at present to the 7th Hussars, and that is the flippancy of the coroner's remarks. The attempts at wit in which he appears to have indulged, and the laughter thereby excited, at an examination of so sad and solemn a nature—these have equally surprised and offended foreigners, and are little calculated to recommend the publicity of judicial examinations."—*Berlin Correspondent of the Times*, August 15.

To say that the person called by competent authority Quackley ought to be removed instanter from the post of coroner, is just to

affirm that the coronership is a responsible office. Is it a magistracy that requires decorum, dignity, moral-worth justice? Look, then, at the Hounslow inquest, and say what word is needed to show the unsuitedness of the magistrate. Is it true that a more perilous spectacle cannot be pictured than that of an innocent man hanging for his fate, in a moment of popular excitement, on the decent fairness and common honesty of Coroner Quackley? And does this desecration of the most sacred of human trusts show itself in a country above all others sensitive to the administration of justice? Why, then, is there a day's delay in ending the judicial infamy? Happily every thing tends to make that effect inevitable. Even the pledge of a Criminal Information against ourselves, given by the accused magistrate before Parliament, cannot be kept, more than the promise of a further investigation by a Government Minister, without securing us the boon; and even if both pledges be broken—as *one* of them will be—the desired consummation can still not be long wanting. The matter is of such importance in a matter all-important to Englishmen—the administration of justice—that the wrong must be forced home, the uncleanliness on this bad magistrate's hands made public, and Government compelled to do the decorous and just thing.

Reviewing the way in which this man *managed* his medical testimony at this inquest, we have, in that *alone*, more than sufficient evidence to convict him of injustice and partiality in their lowest phases; and when we connect with that evidence all the other circumstances of the case, we adduce proof demonstrative that this injustice and partiality originated in a corrupt and wicked intention. This is strong language; and if unfounded would secure us not the menace only, but the *penalty*, of a criminal information; yet we use this strong language most advisedly, pledging ourselves to proofs even stronger.

We contend, first, that the calling in of Wilson was not only an extraordinary and an unnecessary, but also a most improper, exercise of judicial power. The poor man White had died of *acute thoracic disease* twenty-seven days after the flogging, after having previously recovered, according to his own belief and that of competent witnesses, from all the effects of the punishment. The doctor attending the patient affirmed that he died of *acute* pleuritic disease; two army surgeons, unconnected with the flogging, asserted the same thing under official responsibility; two surgeons appointed by the coroner and jury (Messrs. Day and M'Kinlay) subsequently examined and corroborated their statement. If medical men can prove anything in a court of justice—if medical testimony be worth one rush before public tribunals—the scientific testimony was here complete. Suppose Dr. Warren partial; suppose the two army surgeons prejudiced: yet, when the two gentlemen sent by the coroner professedly to oppose them support their conclusions, there surely was an end of all incertitude. The coroner's own two witnesses put him out of court in his unwarrantable suspicion of their three medical predecessors; and, if his former distrust were honest, this extraordinary corroboration in every disputed particular must have completely removed it. To call in another witness would be now to disbelieve, to disparage, to compromise not three but five medical men, two of them his own selection; and where was the pretence for so extraordinary a procedure? Was the man's death not satisfactorily accounted for on scientific principles? It is not affirmed for an instant. Did the four witnesses differ? On the contrary, both sides perfectly concurred. Was there any lack of data? No; for there were two *post-mortem* examinations most carefully made at different periods. Do they suggest that there was any doubt on their minds? No; for they felt none. Nothing of this kind is pretended. We say stoutly and unhesitatingly, then, that there was no legitimate cause for asking for another medical witness; there was, however, abundant illegitimate cause. If it were the interest or the policy of the agitating coroner to continue a popular hate, however undeserved, against Colonel Whyte and Dr. Warren, and to arouse a popular liking, however unmerited, for himself; to go on exciting a mutinous spirit in the army in his favour; to extract from the criminal inquiry he presided over, at whatever cost to others, the elements of *political* notoriety, and the materials for a successful re-election in Finsbury—if such were his intent, and such his policy—the very first of his aims would be to discredit, no matter by what violation of decency or custom, the five medical witnesses; to rake up, at any price or at any hazard, some confidential friend and dependant who would flatly contradict and discredit their conclusions before the public; and, finally, to take care in the meantime to keep those conclusions back from the witness-box till the very moment the adverse witness could be produced and pitted against them. Now, what were the facts? The coroner, finding that his medical witnesses were unanimously of the opinion which would strip the inquest of its tragic interest with the public, refused to hear their testimony! He made a further adjournment, and used the interval in instructing his friend Wilson to get up his set-off testimony to the matplot truths of regular and well-informed science! The evidence of five medical witnesses waiting to be examined is flung back another week, rather than chill with their dry facts the excitement of the public mind!—nay, three of them are actually, by express order, excluded from the public inquest-room, lest they should say anything which, reaching the reporter, might cool the popular ferment! One of these excluded gentlemen, too, Dr. Warren, is accused, by implication, of the crime of murder!

But, suppose the magistrate honest in all this, and unbiassed by any corrupt view of personal advantage or mob-applause, would he yet have selected, to oppose these five gentlemen, his own "intimate"—a man formerly his own servant, writing with him in a subordinate capacity in the same journal, and depending on his patronage for daily fees as an ambulatory *post-mortem*-examination maker? Or would he, when successful in getting adverse testimony in such a suspicious quarter, be so anxious to shut out further inquiry as forthwith to balance, before the jury and the country, that dependant's word with the deliberate evidence of five honourable medical men? If he suspected the evidence of five professional men—his own medical brethren, whose all rested on the goodness of their characters—how happens it that he had no doubt about the commodious evidence of one hireling dependant? If he really distrusted the whole corps of scientific witnesses before him, and really aimed at justice rather than making out a case *coûte qui coûte*, he had surely sufficient common sense to teach him that the proper course—the usual course, the unsuspected course—would have been to call in such unimpeachable authorities as a Knox, a Fergusson, a Sharpey, a Partridge, or a Todd, and so to have corroborated their evidence if opposed to that of their five predecessors, that no doubt could have been left on the subject, and no imputation thrown on their testimony. He did no such thing; he did everything to avoid such a thing: can there be a doubt why?

But the demonstration of a corrupt animus in this English judge does not stay here. By a clever manœuvre, Mr. Day, the coroner's witness, having his testimony adjourned too, is not allowed to commit himself publicly to his known opinion as to the cause of death, and is therefore not yet wholly despaired of. Well: the upright magistrate, adjourning the proceedings, orders that during the third *post-mortem* examination—actually a *third* cadaveric examination!—nobody shall overlook Mr. Wilson but Mr. Day! To get rid of strong opposing medical testimonies, all unanimous, the judge takes refuge in a hireling witness and a hugger-mugger autopsy!—and, therefore, medical men whose liberties or characters are involved in the honesty and good faith of this very suspicious examination, are rigorously excluded—and though Wilson, within a stone's throw, is making extraordinary anatomical discoveries he is forbidden the "satisfaction" of pointing them out to the recognition and discomfiture of his adversaries! The coroner thus selecting a convenient witness *coûte qui coûte*, and thus affording him a very convenient secrecy *coûte qui coûte*, might have been content, one would have fancied, with his pre-arrangements for getting evidence of the required quality; but no: Mr. Wilson receives from him careful instructions: the impartial witness is not to look through the body for the cause of death—but to find it in "the back and spine." "His attention," to use Wilson's own words, "was to be specially directed to the back and spine"! Five medical men were ready to swear that the cause of death was to be found in the state of the thoracic viscera; but Wilson held coroner's instructions to look for it especially in the back! But how stands the fact? *Strange as it must appear, Wilson did not, after all, find the cause of death in the back.* Mr. Day tells us in positive terms, in his letter to the *Times* of August 15, *That during the examination, and afterwards, while drawing up the report of its incidents, Wilson did not hint that the back had anything to do with the death; that during that day Wil-*

son quite concurred with him, and, consequently, with the four other medical witnesses, and the he—Day—after seeing and hearing what he did at the autopsy, was "exceedingly surprised," at the inquest, to hear Wilson's subsequent "imaginings" and "after-consideration" fancies, given in evidence to the jury as his deliberate medical opinions! The witness so chosen—so helped by secrecy—so instructed—came away from the autopsy, like the others, another Balaam blessing those he was sent to curse! How happens it then—everybody asks—that we have from this same Wilson, given with the sanction of an oath, testimony so strangely changed, and so awfully agreeing with his coroner-friend's views? We do not profess to divine, but indisputably it is the strangest, the gravest, circumstance in medical ethics that ever came under our attention as journalists. Connecting with so mysterious a vicissitude and transmutation of scientific *fact* the studied vagueness and absurdity of the anatomical language by which the afterthought conviction is supported, and remembering that the liberty, perhaps the life, of a brother medical man rested on the startling testimony, we shudder as we think, and ask, is this the criminal justice, are such the criminal witnesses, secured us in our country under a British magistrate, responsible for his conduct?

But if the way in which the coroner managed to get up Wilson's evidence deserves the strongest reprobation, what shall we say of the evidence itself? For palpable absurdity in intrinsic nature, as for daring atrocity in purposed result, we defy its parallel. What the testimony of Titus Oates was in politics, this is in science. The whole medical world is aghast at its stupendous falsehood. Passing by the singular phraseology and curious omissions of his testimony, imagine a *lecturer* on anatomy swearing, in so many words or by implication, that the well-known phenomena of decomposition presented by a body in the last stage of putrefaction, are the result, and can be the result, of nothing but a change of structure in living fibre!—that the *multifidus spinæ* lies on the membranes of the chest!—that this half-tendinous and inert muscle had been suddenly seized under the flogging by convulsions, which left unnoticed the energetic and susceptible masses of muscle superimposed from the longissimus dorsi to the integument!—that either an inflammatory action in this muscle traversed a plate of bone more than half an inch thick and reached the pleura, or else that no such column of bone intervenes between the two localities!—that a portion of a muscle, acting always instinctively and entire, took on a convulsive action in direct antagonism to all we know of the law of respiration!—that the two intercostal muscles, instead of acting in invariable unison as usual, became disassociated and acted separately!—that the spinal portion of the intercostal is in immediate contact with the pleura!—that disorganization of the muscles after flogging, with acute inflammation of the thoracic viscera, naturally took place on the side least injured by the punishment!—and, finally, that a man who survives a flogging twenty-seven days, and who dies under all the symptoms of acute pleuritic disease, would *certainly* have defied death except for the corporal punishment! A London lecturer on oath venting such testimony! With the fact palpably before us, we confess we can yet hardly muster credence for it! Yet it was by such evidence, and so manufactured, that the solemn judgments of five conscientious practitioners were to be disproved, and their reputes damaged. Dr. Warren possibly placed on his trial for liberty and life, and a vast *political* delusion maintained in its integrity in the public mind! What language of denunciation of either the witness that gave, or the magistrate that sought and adopted, the testimony, can adequately describe their conduct? We know of none.

Sensible men ask how it is that, after all these showy and artistic preliminaries and concomitants, the inquest could have resulted in so "lame and impotent a conclusion"—

"Amphora cœpit
Institui; currente rota, cur urceus exit?"

We had first the newspaper supplied with reports; a most mysterious opening of the inquiry; repeated adjournments to suit the conveniences of the Sunday's press; irrelevant examinations and correspondence, gibes, gambols, "flashes of merriment setting the table in a roar"; sententious sayings, "de omnibus rebus et quibusdam aliis"; three *post-mortem* examinations; a convenient witness—more bedizened with celebrated certificates than a twice-plucked pupil—brought express from London to startle the public and amaze scientific men with pathological discoveries made expressly for the occasion; medical men rigidly excluded from a public inquest-room; a melodramatic examination *preceding*, a mysterious secrecy *accompanying*, the *post-morten* examination—in short, justice, order, propriety, all broken and violated to invest the performance with tremendous *eclat*—yet all ends in the verdict that the flogging was legal, and its administrators free of blame! The fact appears to be that the magistrate, who began the inquiry with all the fanfaronade of the Hector, finished it with all the timidity of the coward; and was as much in fault in the craven conclusion as in the braggart commencement. If the flogging killed the man, then was Dr. Warren responsible for the consequence. The case instantly became one of manslaughter; and, whether the guilt by negligence or ignorance was great or small, a criminal investigation was imperatively called for. But that investigation would have given the whole question a fair trial before an impartial tribunal; and hence, after teaching the public, through Wilson, that Dr. Warren allowed a patient to be flogged to death, the coroner is the person to let Dr. Warren go abroad untouched, unaccused, everything but *unslandered!* Besides, if the court-martial was held, as "Coroner Quackley" tells us,* on a warrant signed and issued fourteen weeks before any offence was committed, it appears to us difficult, on constitutional principles, to deny that the whole process of martial law was illegal from the commencement, and, consequently, the "flogging to death" must have amounted to murder. In a double way, therefore, the magistrate had the opportunity of giving full practical effect to the views he pretended to entertain of the case; but in a double way he declined. He was very ready—very *daring*—for any amount of *wordy* humanity; but when it came to honest deeds and actual risk—he would rather not, thank you!

But the magisterial indecencies were not done with the trial. The president of a criminal investigation—most *criminal!*—is afterwards seen publicly lauding or vituperating, in the House of Commons, British witnesses, according as their testimony had been made to subserve his political views in the inquest court: is self-confessed to have gone begging to an humble country attorney for certificates of his decent behaviour as a British magistrate; and, finally, is witnessed presiding over an agitating meeting—addressed by Cleave, Vincent, and other orators of similar political views—held to sustain strongly-partisan opinions on the very subject he had been inquiring into as judge; a meeting, too, at which sentiments the most mutinous were addressed to the soldiery present, and proposals made by the very coroner himself for a handsome money allowance to a military witness of impeached character, who had given testimony at the inquest favourable to the well-known bias, nay, to the well-known interest, of that coroner!

We will not now encroach further on the public's attention, save to register for the third or fourth time, in the strongest language we can command, our unalterable protest at the utter, the disgracefully utter, unfitness of such a functionary to discharge the trust of an English magistracy. Neither liberty, nor character, nor life can be safe while so unfair, so unscrupulous, so dishonest a partisan desecrates the judicial seat. His presence there is a denial of impartial justice to the public, and is an opprobrium and a stigma on our judicial character in the eyes of all nations. The general prostitution of our criminal jurisprudence to the purposes of private or political needs, is the question his conduct raises in issue; and the inquest at Hounslow, with its ruthless sacrifice of good men's repute, its unprincipled enlistment and welcome of *Wilsonian* evidence, and its tragi-comical management of almost every incident in the important case, is proof conclusive, without any of the incongruous and startling *sequelæ*, that there can be no court of justice unpolluted which this libellous journalist, this violent agitator and sham "*humanitarian*"—is allowed to disgrace with his presidentship.

* In divulging this grave circumstance at the meeting at Exeter-hall, this upright magistrate said he would have kept it a profound secret if he had not been so attacked!

Misce stultiam consiliis brevem:
Dulce est desipere in loco.—HORACE.

It was our intention, at the close of July, to offer sundry words of advice to students; but other business more immediate having demanded the services of our pen, we have been compelled to postpone a few ethical phrases until this late season. Upon the good old principle, however, of "better late than never," we offer this short apology, sure that it will acquit us of anything like deliberate forgetful-

ness towards a community we have ever taken deep interest in.

On the commencement of last winter session, we greeted our old pupil-friends afresh, and gave a cordial welcome to the recruits of our goodly corps; and subsequently suggested to these latter the best means of prosecuting their studies and providing for their health. Taking for granted that our advice was followed, and that the winter and summer sessions have been passed through in all diligence and discretion, we have now to consider the welfare of our young friends during the period of vacation.

Only those who have sojourned for nine studious months in London, solitary and self-devoted, amidst the din and bustle and gaiety around, know what the pleasure is of breathing a pure air, and having a few friends they can call their own, and a few idle weeks they can afford to do as they like in. Studentship is all very well to make a jest of by those who can afford it, but to those who cannot it is a very different affair. The man who is his own master, in person and pocket, can indulge freaks of study and of relaxation just as the whim may seize him. What is voluntarily imposed or inflicted can scarcely be considered a trouble or a penalty, because the will that orders, can as easily countermand, obedience; the burden, therefore, if such it be, is sustained willingly, from a consciousness that it can at any moment be disposed of. This is one of the many things that make *volition* one of the loftiest, as well as the most agreeable, attributes of our nature.

Without pursuing this train further, we may affirm, without fear of contradiction, that, in pleasantness and comfort at least, there is no comparison between the studentship that is self-imposed and that which is forced upon us. To take up a book, conscious that you can lay it down when you will, and be responsible to no tribunal for the freak, is to make the study of that said *tome* the reverse of burdensome. And many is the time when a disposition to a little amiable idleness, or an utter unfitness for fixing the attention and exercising the memory, would induce one to throw all care for facts aside, and revel luxuriantly in unstudied flights of fancy. We envy not the poor slave who has never had promptings like these, but, dray-horse like, is ready for his work whenever it is duly allotted him, and the time has come for its performance. Such men are non-naturals, and not worth the regard of anybody. The reverse of these are the men after our own heart; and right sorry are we for them when not able to "do as they like" with what would seem to be "their own," viz., themselves, and the scrap of time apportioned them to live in.

This, however, must be considered the fate of medical students whilst under the trammels of probation. There is a serious obligation at hall, or college, or university, or some such place, that demands constant care and anxiety to secure the due discharge of it. To this end the student is bound to consider himself not his own master, but the slave of his subject, until it be fairly off his hands. His time is not his own—his talents are not his own—nothing, in fact, is his until the incubus be off him. It lies a heavy load upon his conscience, and weighs down any pleasantry of heart that would arise within him, to claim kindred with the laughing spirits less fettered than himself. The curriculum of study, and of examination, is always before his eyes; a floating mist of miserableness that obscures all the brighter objects that flit before him. There are these books to read—those bodies to dissect—the other lectures to attend—all these things, like imperious creditors, are at him incessantly, and no wonder that their din drives him into solitude and abstraction. There he is, poor fellow, closeted like another anchorite, wrapt in his own reflections, and as completely alone in the world as though he were the only living object inhabiting it. If he go out for a breath of fresh air, it only occurs to him as a medium containing more oxygen and less carbonic acid than the one he has just left. If he gather a flower, it is only to look at it with a botanical eye, or to inhale its aroma with a scientific regard to the chemical constituents thereof. If he pass a rippling river that would once have brought Isaac Walton or a stray sonnet to his remembrance, he thinks only of the anatomy and physiology of fishes and the composition of water. He lives utterly in a scholastic medium. In the country—

"He only sees the leaves of trees exhaling oxygen."

In town—

"He only sees the lungs of men inhaling it again."

At home—

"He cannot dance, his only steps are up the stairs to class;
He cannot laugh save with a dose of nitrous oxide gas;
He cannot sing a merry song, or take his toddy free;
He's just a moving mass of strong specific gravity."

Ask him to the theatre—he says:—

"I cannot go—
The stages of a fever, now, are all the stage I know;
Instead of Murray's Turner Giles, I've Murray's Pharmacy;
The operation benches are—box, pit, and gallery."

No wonder that, after some months' sojourn in an artificial state of thought and feeling like this, body and mind should both suffer and yearn for relaxation and a more natural state of existence. These latter are the blessings that the student enjoys during the months of vacation. Text books, and tomes of every sort, are thrown aside, or rather carefully packed up, until the forthcoming October—the dissecting-room is bade a polite and not reluctant farewell—the small, dingy, dirty lodging-room, and its smaller appendage, yclept a dormitory, are left to the solitude befitting them—and the pale-faced, sunken-eyed, melancholy inhabitant, accompanied by his wardrobe and a pleasant companion or two out of his library, is off to the old house far away in the country to enjoy the society of his friends, and luxuriate on fresh-laid eggs, draughts of new milk, and breezes of pure air. How he greets everybody when he gets among the familiar faces of his childhood, and how everybody greets him, we do not pretend to say. He has been away for nine months, and, of course, must be so altered and unlike himself that he needs almost to be ticketed or franked, to be taken in. The London tailor has sent him home in such habiliments as were never seen in the village before—and not only in these, but in every thing, from his hat to his boots, he is so at variance with what he was, that he might have walked straight through the hamlet, and into his own father's house, and the bewildered gossips would have wondered whoever the stranger could be! An old twinkle of the eye, however, and an old curl of the lip, tell of the absentee; and the cordial hand that bade him good-bye, and the starting tear that more eloquently than words spoke "God bless him," a few short months ago, now testify their feeling afresh, in welcoming him back again to the scenes of his earlier lifetime. After all, this is a greeting worth the agony of parting and the pains of lengthened separation. To the young heart, fresh in its tendernesses and troubles and eloquent susceptibilities, it is especially so. This is the season when one's nature is most alive to the good or the evil that threatens it, and when the stamp of either may fix upon us its fatal impression for ever!

Well, our young friend is fairly at home—has *passed* the usual routine of inquiries from father and mother—an examination that is oftentimes not easy—has received the caresses of brothers and sisters, and the casual greetings of the old familiar friends who remember to have nursed and kissed him when he was a baby, and wonder why they should not nurse and kiss him now—he has got over all these things, we say, and no doubt lots beside. What is he to do next? Why, if he take our advice, he will take good care of himself. He has left one scene of bodily sacrifice: his great concern should be not to fall in the way of another. It is the custom now, as we understand it was of old, to kill the fatted calf by way of welcoming the stranger home. This said feat of butchery would be all very well, provided the stranger were not expected to perform more than his own part in the great pantomime of devouring the sacrifice. But, unhappily for the lion of a party, he is always expected to eat the lion's share, and this regardless of his inclination or ability to do it. We know what it is to be feasted by friends who have not seen one for months, and expect that we shall swallow at a sitting all the eatables and drinkables they have been registering to the account of our appetites since we parted. Such people have no idea of dyspepsia, nor of bursting either. One might be a boa-constrictor, fed only at distant periods, and no matter with how much at a time.

The things that we are discoursing of are the follies, rather than the faults, of friends; they come with the best intention; but, if allowed, they are not generally followed with the best results. We would especially advise the student to beware of seeming trifles like these. If he do not they will prove troubles to him. He is already shattered; he wants recruiting, invigorating, and fitting again for severe work. A vessel disabled at sea would do no good by toying with her own weakness whilst in harbour for safety. This neglect of opportunity would either consign her to the ship-breaker or to the wave. So it is with the student. Returned home, shaken by the toil and anxiety of serious study, it concerns him to repair the havoc and injury his constitution has suffered during his period of confinement. Let him thank God when the blue sky beams

and the pure air breathes upon him! He can never value their goodness too highly: he can never be too grateful for the benefit they bring him. They are not trifles in his way, but tributes to his existence; and the abuse or neglect of them carries something suicidal with it!

The subject is important enough to induce us to hope we may be able to treat afresh, and terminate it, next week.

ANNIVERSARY MEETING OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

The fourteenth anniversary meeting of this association was held at Norwich on Wednesday and Thursday the 19th and 20th inst.

At one o'clock on Wednesday the first general meeting of the association took place in St. Andrew's-hall.

J. G. Crosse, Esq., having taken the chair, was warmly applauded, and, after acknowledging the reception he had met with, said,—Gentlemen, in entering upon the high office to which I am now called, I feel incapable of saying anything that can adequately portray my excited feelings. To be placed nominally at the head of so large and influential a body as the Provincial Medical and Surgical Association, composed of above two thousand members of our profession, is, indeed, a giddy height, which must be perilous to myself, and can be rendered secure only by your further kindness and support.

I consider it an auspicious day for the profession in this district, that in our ancient city, situated so remotely from the great moving centres of human life and action, so many gentlemen of respectability, talent, and distinction are assembled together for purely scientific and social purposes. The numerous body already present offer a sufficient guarantee that much is about to transpire; and as time, always precious to all, is particularly so to ourselves, I will not detain you longer with merely introductory remarks.

I well remember, at an early period of my residence in this city, becoming acquainted with an extraordinarily endowed individual, who had travelled throughout Europe, and gained access to a great majority of the sovereigns, judges, prelates, and other men of high estate in each country that he visited, and he assured me that his plan was always to inquire for the leading medical men of every town he entered, finding it the readiest way to get access to the highest and the best-informed classes of society. I have every reason to believe that the favourable character which my itinerant friend expressed regarding the medical profession continues to be fully maintained, in the provinces, not less than in the metropolis of this empire. In almost every considerable town, the physician or the surgeon acts the Mecænas, to the full extent of the time and means at his command, towards all intelligent and scientific men resident in or visiting his locality; and well may the medical man estimate science, and desire thus to encourage it, since there is scarcely any branch of scientific knowledge that may not, in some way or another, be applied to his calling, whether we look to daily social intercourse, or to the nature of diseases, and the various appliances for their relief, prevention, or cure.

A warm zeal for medical science is undoubtedly the great source of its advancement in this country, where the Government has done, and perhaps is capable of doing, so very little; but one of its recent and most valuable acts deserves to be mentioned—the annual report of the Registrar-General, which, worked up to the highest pitch of correct mathematical calculation in the department which relates to disease, promises to supply great advantages to the State, and to be a guide to our prudential institutions for life insurance; towards these improvements every practising man gives his gratuitous aid, by furnishing certificates, for which the public remain indebted to him. In the army, medical officers continue to perform laborious duties by furnishing reports, and the public are as much in need and as much entitled to an annual summary of what transpires in the civil department: but those documents continue to accumulate, without being converted to any proper statistical account, and must, in course of time, increase to so unwieldy an extent that nothing but a deluge or a conflagration can dispose of them. The Government is just beginning to direct its attention to sanatory regulations throughout the provinces, which must prove a national benefit; and perhaps we may regard the arrangement for partly remunerating the most working members of the profession, the union surgeons, out of the public funds, and thus connecting them with the state, as a movement in the right direction, and a security for further improvement in the medical care of the poor.

As a science to be studied for the public good, legislation on medical matters is entitled to every consideration. Until recently, it received less attention from the Executive in this than in almost any other civilized country in the world, although the profession have been agitating the subject for nearly forty years, to my knowledge, but most warmly in the last three or four years. And, after all, what are the conclusions most generally arrived at and avowed by the greater number of thinking and experienced men? A few general principles are what they agree upon; and foremost may be placed a general registration of all legally qualified, with annual publication of the registry. The next are uniformity of education and community of privilege in each grade throughout the empire—principles which will be more appreciated every year, by the increasing intercourse which rapid and easy transit is sure to produce, rendering the present incongruities more and more apparent, until they will be deemed too absurd to be longer maintained, and we shall see the profession in England, Scotland, and Ireland united in one brotherhood. It is not a little extraordinary that "the protection to the public by penal laws against the unqualified" seems not to be so generally admitted as a necessary principle of legislation. To carry out the principles I have enumerated would be, in my humble view, a great boon to the public, and not less so to the profession; and all minor details are scarcely worthy to be regarded as immediately essential; particularly at the risk of our getting nothing done; in grasping at the shadow we may lose hold of the substance.

But there is one truth worthy of being made prominent, and of being frequently placed before us—sound legislation will benefit, but the influence, respectability, and high *status* of the profession in this country must be secured and maintained by very different means—by knowledge honestly applied—by integrity, assiduity, kindness—by the absence of all contentious, narrow, over-selfish, and grovelling passions—by liberality and forbearance towards each other—and I may be permitted, I am sure, before the present company, to add, that the exercise of all these virtues which I have enumerated, and their results, will be greatly promoted by social and scientific intercourse with our brethren, such as the Provincial, and all other associations in the empire, are calculated to foster and promote.

But the best prospects are held out when the improvement of society at large accompanies that of the profession; for how much depends upon the state of the public mind, its information and its power to discriminate! A powerful influence is reciprocally exercised between the public and our profession; in the Metropolis and with the preeminent it may be otherwise, but in provincial towns, every medical man may be said to practise in his own atmosphere. The grounds for selecting an ordinary medical attendant are as various as the dispositions, tempers, and minds of individuals; these are matters to be left to their own unavoidable course. Disregarding as far as may be the whims and prejudices of the public, we should direct our minds intently upon these three objects:—The full attainment of the sound medical knowledge of the day—the diffusion of what knowledge we possess—the advancement of medical science! On each of these a man may base a solid reputation, but on account of the last only can he be considered as entitled to renown.

As to that notoriety, disconnected from superior knowledge, and depending on transient multitudinous applause, it ought to be little prized by members of such a profession as ours; rarely, if ever, is it durable, never satisfactory. The public favour, on which such notoriety floats, has been compared by one of our greatest writers to a running stream, which lifts the frothy and light materials to the top, but lets the solid and weighty sink to the bottom.

"*Levia et inflata attollit, gravida et solida mergit.*" It enables our calling to endeavour rather to correct the defective information of the class of society we approach, than to convert it selfishly to our advantage. How much at our mercy is the *malade imaginaire*—the greedy consumer of innumerable doses, till he is more sick from the medicine than the disease, "always tampering with his health till he has spoiled it, like the foolish musician, that breaks his strings with striving to put them in better tune." Happily the medical is not often charged with being a sordid profession, and few, very few, it is to be hoped, are justly entitled to the sarcasm of the greatest of English satirists, who has hinted that there are some who attend

"Not for the sickly patient's sake,
Nor what to give, but what *to take*;
To feel the pulses of their fees,
More wise than fumbling arteries;
Prolong the lamp of life in pain,
And from the grave recover gain."

Perhaps Plato had such in view, when he stated it to be a sign of a bad commonwealth, if physicians were very numerous; it would be a bad commonwealth to the physicians unless diseases were numerous also.

That our ancestors knew a great deal is unquestionable, even much that has been forgotten and that has passed away; but it was known to very few. The striking characteristic of the present day is, that what is worth knowing is known to a great many, and is accessible to the whole profession. It is on this more extensive diffusion of knowledge that we may justly claim superiority over our ancestors; the increased and yearly increasing proportion of well-educated members of our profession, and the diminished numbers of the grossly ignorant, are indications of our improved condition, quite as much as the advanced degree of our science. New and brilliant discoveries—often more imaginary than real, more vaunted than prized—are, as the pinnacle or spire of a fine edifice, attracting much attention, whilst its basement and interior correspond to that well-diffused, sound, practical knowledge, which is of every-day application, and can now be found in every part of our favoured country. That the diffusion of such useful knowledge is promoted yearly by the meetings of this association can scarcely be denied; let us endeavour that this and every future occasion shall be an improvement upon the past, and let each of us remember that what takes place in this public room may be considered as transpiring before the medical community, as well as before the criticizing spirits of the day, who take so much better care over our interests than we seem capable of doing for ourselves.

It must necessarily happen that a vast majority of our profession can aspire to no greater merit than that of collecting facts, for which, however, they deserve approval, and even commendation, if their facts be *true* and *real*; for it has been remarked, with some justness, that there are as many false facts as false theories. Mere facts, however closely connected, are as distinct from science as colours on the pallet from a beautiful picture worked out by the talents of an artist. In medical science, facts are the materials for a building, and require to be converted, by the operation of the minds of the more gifted amongst us, to their proper object—the awakening of philosophical ideas, and the construction of a theoretical system for our guidance. But the reverse of the inductive is too commonly the course pursued, even in these enlightened days; theories are first formed, and the facts are made to come afterwards, suitable to

the preconceived speculations; and it is melancholy to reflect, that when once a theory has taken possession of the mind, it cannot be displaced without offering another in its stead, often as delusive as its predecessor. Rarely, in these modern times, has medical science been beset with more bewildering theories of the day than at present; what one man honestly espouses, another ridicules and despises, and in the collision thus arising is found the wonted stimulus to mental activity; but that the infinitesimal follies of homœopathy, the drolleries and deceptions of mesmerism, or the more dangerous excesses of hydropathy, can ever long persist, or any one of them be brought to the position of a science worthy of general support, will, I trust, scarcely be admitted by the present enlightened assembly. Theories are unavoidable, and, where they are honestly embraced and used, to a certain extent, desirable, and may even prove useful; but were the great body of the profession —nay, were any preponderating number of this large association—to become captivated with any delusive doctrine, and to merge into the fanaticism of the day, we should be driven back to the dark ages of our history, denominated by a learned professor the stationary period of the inductive sciences, "when experimenters were replaced by commentators, criticism took the place of induction, and instead of great discoveries we had learned men."

One of the possible advantages which may arise from homœopathy is, that it will afford opportunity for observing the natural course of diseases, and be a check to over-active treatment in doubtful cases. In our difficult calling, whenever art does violence to nature, the apparent good is as an artificial fountain, that can be kept up only for a time; the more you consult the restorative powers of the constitution, the more surely will progress towards recovery, once commenced, flow in a smooth current, like a natural rivulet, till health is restored.

I must now enter upon topics still more serious and grave, yet which it would not be allowable to pass over in silence. The Hippocratic remark, that "life is short," may be applied most emphatically to gentlemen of the medical profession, who, on an average, live for fewer years than members of the other learned professions, notwithstanding the advantage the former might be expected to possess, in a knowledge of the first approaches of disease, and of their causes, with the means of prevention. It is difficult to state in few words to what this is attributable. The incessant and wearing duties of the medical man, and the impossibility of having any regular relaxation, tend mainly to shorten his earthly career. The attendant anxiety about patients, and about the means of a scanty livelihood, aided by the depressing influence of constant scenes of distress and suffering, may be added. Besides, the medical man never shrinks from attending a contagious patient any more than a brave soldier shuns the field of battle! How nobly and disinterestedly did our profession rush into danger, at the call of duty, when the Asiatic cholera, some years since, devastated certain districts in this country with an appalling rapidity and fatality—receiving in return the most groundless accusations from the uninformed and affrighted multitude! and more recently, in the instance of the "Eclair," did not several of the best of our brethren, volunteering service, perish under African malaria and pestilence?

But, apart from all extraordinary dangers, I find reason to believe that, under ordinary circumstances, in this district, and in the provinces generally, medical men on an average continue to meet the labour and duties of actual practice in their profession, little more than twenty years—a brief span indeed, scarcely thought of, and never rightly estimated by the young aspirant to public favour. Yet few have stronger reasons to calculate correctly than the medical man, who is usually so circumstanced, with others depending upon him, that self-preservation ceases to be selfish.

What I am about to state will appear contradictory to the preceding observations, and yet it is perfectly correct, so far as I have been able to ascertain, that since the last anniversary, and amongst one hundred and eighty members, composing the eastern branch, not a single death has occurred. The rest of the association may well exclaim to their eastern associates, "*O fortunatos nimium*"! and caution us to make the best use of our time, as the ensuing year may be expected to produce a different result, and to adjust the balance! Nay, even whilst I am thus engaged, I have to correct the statement and to record the decease of an eastern member, who was above ten years a zealous and steady supporter of this society; I allude to Dr. Chevalier, of Aspall, who, during a long life, and under the pressure of more diversified occupations than fall to the lot of most men, showed a disposition to "scatter oil over the troubled waters," and make all happy around him; he was more conspicuous for his amiable virtues than for his medical practice; with pious resignation he bore the inflictions of a painful disease, and sank into the repose of death in full and perfect hope of eternity!

The year's obituary of members resident in other parts of the kingdom is too long to permit of a full notice of each; neither time nor materials are at my command, for until a recent hour I knew not that this office would be assigned to me; but if an opportunity occur, and further information should reach me, I will enter upon the duty, most congenial to my feelings, of doing honour to the deceased, which is so powerful a stimulus to the living to emulate good example.

And now I must conclude my initiatory remarks, with expressing a fervent desire that all the occurrences of this anniversary may be calculated to do honour to our profession, and to promote the best objects of the association—science, cordiality, a beneficial knowledge of each other.

I must avoid prolixity, as it must throughout our whole proceedings be avoided, for economy of time. If brevity be the soul of wit, it is equally so of science, and of all that is practically useful and available in our busy life. Whatever comes before so numerous a meeting of the profession, as is now assembled in this city for the first time, and probably for the last in our day, should be well weighed and considered, and the motto worn by each contributor to our proceedings should be "Fugit irrevocabile tempus."

Dr. Streeten then read the report of the council, which was a very voluminous document, and which showed the affairs of the association to be in a fair condition. The report spoke favourably of the intention expressed by the late Government, of taking the payment of poor-law medical attendants partially out of the hands of the guardians of unions, as well as of the extensive measures proposed for the improvement of the sanatory condition of the working classes.

Dr. Hastings then read the financial statement of the association, from which it appeared that there was a balance in hand of £113 7s. 6d.

The following gentlemen were then admitted honorary corresponding members of the association:—Andeoz Adolph Retrain, of Stockholm; Dr. Ware, of Boston, United States; and Dr Oppenheim, of Germany.

After this Dr. Chambers read a paper on disease of the heart, which he attributed in many cases to the sudden adoption of total-abstinence principles.

The meeting then separated until the evening, when the members again met at St. Andrew's-hall. Soon after eight o'clock the chair was taken by the President, J. G. Crosse, Esq., who stated that he had one suggestion to make relative to an important resolution adopted in the morning, appointing a committee of gentlemen to inquire as to the mode of carrying on the publications of the association. That committee was instructed to report to the council, or to the next meeting of the association, on this point. The gentlemen had been selected for the interest they took in this matter; but there were two gentlemen present whom it was desirable to have added, namely—Dr. Chambers, of Colchester, and Dr. Durrant, of Ipswich. The Chairman then moved that the above two gentlemen be added to the committee.—Agreed to unanimously.

The report of the medical fund committee was then read and adopted.

Mr. Daniel read a report from a committee appointed at the last annual meeting at Sheffield, to consider the propriety of establishing a general annuity fund. The committee recommended such a fund to be established. An appeal had been made, to which sixty-eight members had responded; fourteen had subscribed; nine had paid donations amounting to £47 5s.; about twenty others had intimated their intention of becoming subscribers. Mr. Daniel, having read the report, appealed to the members to give the project their support. One reason he gave was, that the lives of medical men were more precarious than those of other professional men; in proof of which he stated that forty-three divines of every thousand lived to the age of sixty-six; whereas only twenty-four medical men of every thousand lived to a similar age. Mr. Daniel concluded by moving that the plan be received and recognised by the association.

Dr. Hunter, of Lynn, seconded the proposal, on the ground of its benevolent and useful character.

Dr. Conolly opposed the proposition.

A Member present expressed his gratitude to Mr. Daniel for his exertions, and the ability displayed in promoting the benevolent object he had brought forward. This feeling was warmly concurred in by the meeting.

Mr. Firth, of Norwich, read a paper on poisoning by arsenic, founded on the cases at Happisburgh. He stated that he had found arsenic not only in that part of the soil in the churchyard at Happisburgh where interments took place, but also in another part of the ground which had never been opened for the reception of the dead. Mr. Firth stated that he was still pursuing his experiments on the subject.

Several other papers were then read, and the meeting adjourned to Thursday.

On Thursday, soon after twelve o'clock, the third and last public meeting, at St. Andrew's-hall, was held. The chair was taken by the president, Mr. Crosse. In opening the proceedings he said they were now commencing the third meeting of the association, and he trusted that what had already transpired had so far excited an energy and proved a stimulus, and that as they proceeded they had progressed, and that this third meeting would be a further improvement on the preceding ones. He had every reason to believe that the association was satisfied as far as they had gone. He would not interfere with the privilege which gentlemen would now have of presenting such cases as might be deemed worthy of their attention. It would be only to waste their time to address them further in reference to the business to be brought before them; the best thing he could do would be to offer a few illustrations of some singular exhibitions, relative to medicine, in former times in this city, and the state of the profession at a remote period. His first illustration would refer to quacks. The information he was about to submit, he had obtained through a gentleman who was an antiquarian of great research, ability, and assiduity: he referred to Mr. G. Johnson, who was not a member of the profession. That gentleman had been employed in investigating the records of the city. He (Mr. Crosse) had obtained through Mr. Scott, one of the oldest if not the oldest member of the profession in the city, some extracts furnished by Mr. Johnson of occurrences that took place in this city and the immediate district. In 1690 the magistrates made an order that Dr. William Reid had agreed with the corporation for a stage, for the sale of medicine, at the end of the hall in the market, but not to interrupt the people coming to the pump. Another was, that Dr. Charles Bedest have leave to erect a stage upon St. John's-hill to vend his drugs, with music, to continue three weeks, he and his servants behaving themselves civilly. Another was, Cornelius Tilburne was allowed to set up a stage to practise chirurgery and physic, with music, in the city for one month. Richard Kirby was allowed to erect a stage on the "backside" of the Blue Bell, with music and eight servants, to continue for the space of fourteen days, they keeping good rule and order. From these illustrations connected with a branch of the profession, it would appear that these characters were authorised to traverse the kingdom. Mr. Crosse then proceeded to notice some provi-

sions made for affording medical relief in extreme cases to the poor at that period. Although the poor law was then in existence it was not applied in extreme cases in affording relief; that relief came through quite another channel. Charity was not so rife then as it is now, and it was necessary to have a particular channel for authority to appeal to the public. One extraordinary matter was to obtain funds for persons who sought the benefits to be then derived from the royal touch. There was first a sum of 20s. towards defraying the expenses of John Edwards going to Newmarket to be touched by Charles II., who was supposed to possess a wonderful power of curing. Another record was, that the wife of John Mills should have 30s. "out of the hamper," for travelling to and returning from Newmarket; and "Mr. Town Clerk was to write to know the day of healing." This was in March, 1683. This district was well known throughout the world to furnish an extraordinary number of cases of calculus of the bladder, and was also well known for the same thing a century ago, and was referred to in the document from which he was quoting. To go further back still, it would be found that the clergy, the chirurgian, and the doctor exercised the same function. Not far from this city was a monument erected to a clergyman, who was also a great chirurgian, and who would appear to have had much success in cutting for the stone; there was also a representation on the tablet of the instruments he had used. In 1642 there was a committee of four gentlemen, all esquires, who were desired to wait on the bishop to ask his license to have a collection made to pay the charge for cutting seven poor persons for the stone. There was a similar instance of relief for Robert Hubbard and several other persons suffering from the stone. John Wrench was directed to wait on the Lord Bishop to ask his license to solicit charity from well-disposed persons in the parish of Thorpe. There was an instance given of £3 having been paid to Dr. Hagan, who cut a child for the stone. There was paid a sum of £5 in 1705 to Dr. Goodrick for cutting several persons for the stone. He (Mr. Crosse) was not able to learn what was the result of the operations in these cases. In 1706 there was mentioned another collection; and from this it would appear that the amount of the fee had increased, or perhaps the reputation of the doctor, who obtained £5 for cutting a poor child in Pockthorpe, one of the most destitute parts of the city. There was another case mentioned: Mr. Sadd, a surgeon, curing Susan Copley of cancer in the breast. Any one who could do this in our day would indeed be an acquisition—(Laughter). He would not detain them any longer, but would now call on Dr. Rankin to read the retrospective address.

Dr. Rankin then rose, and read a very long and elaborate paper, comprising a critical detail of the principal medical observations during the past year, with particular cases noticed, and remedies recommended by eminent members of the profession in all countries. Dr. Shearman, of Rotherham, was then appointed to deliver the retrospective address for 1847, and Mr. Walshe, of Worcester, was requested to deliver the retrospective address on surgery for the same year.

The next annual meeting was then appointed to be held at Derby, under the presidency of Dr. Highgate. The anniversary dinner took place in the evening, and was attended by upwards of 130 gentlemen.

MISCELLANEOUS CORRESPONDENCE.

COURTS OF SEDITION.

[To the Editor of the Medical Times.]

SIR,—In my former letters I have protested against coroners' dictation and against coroners' surgeons, but there are still many points in the Hounslow inquest left for consideration.

At the first institution of the coroner's court, the persons that first passed the dead body constituted the jury, as they were supposed best competent to judge of the cause of death. Now, however, small shopkeepers and other uneducated persons generally undertake that office.

In civil as well as in criminal cases the law recognises two juries—the common and special, the latter being employed in all cases requiring more education than ordinary, as being more competent to sift the case and return a verdict according to its true merits.

If we examine the evidence adduced at Hounslow, and divest it of all technicalities and mystifications, we find that a man was flogged, that an interval of time elapsed, and that the man fell ill and died. Upon this the jury returned the *logical* verdict of "Died from flogging."

It is quite unnecessary for me to point out the absurdity of their reasoning, for every educated or even unprejudiced person would at once perceive it, and to such a jury it would be impossible to explain it.

According, however, to such logic the jury would find all persons die of floggings (for, as children, all persons have been smacked when naughty); an interval of time elapses, they fall ill, and die.

Such is the effect of employing incompetent juries, who are led by declamation and not by fact; but it is an awful reflection for them to consider that they were sworn to inquire into the cause of death, yet that they returned a verdict contrary to fact.

The power of a dictating coroner to excite a jury is now apparent, for any coroner wishing to excite any rebellion has only to inflame the jury's mind, when the mischief may communicate to the rest of the community.

It appears that Wakley, within a very few days of the termination of the inquest, attended a meeting at Exeter-hall, where Chartists and other violent politicians were collected.

There can be no doubt that the Radical coroner thought by his sly movement that he should win the affections of the entire army, and, if he could only succeed in this object, might we not expect him to attempt to assume its command, and to issue a proclamation as its chief? The coroner's court, then, instead of being a safeguard to the subject, is being employed for revolutionary purposes; and a court of inquiry is converted into a court of sedition.

This is a novel attempt to undermine our constitution, and I call upon every Englishman to endeavour to restore the coroner's court to its pristine integrity.

I remain, Sir, your obedient servant,

A CONSTANT READER.

GOSSIP OF THE WEEK.

ROYAL COLLEGE OF SURGEONS.—Gentlemen admitted members on Friday, August 21, 1846, viz.:—C. Tipple, S. Sprigge, T. Macartney, T. M. Ward, H. Beckwith, N. G. English, G. Annis, J. J. O'Dowd, P. F. L. N. Delarue, J. Conan, L. Lodge. The court of August 21st was the last court to be held during the present session.

KIEN-LUNG, EMPEROR OF CHINA.—One day the old Kien-Lung, Emperor of China, asked George Staunton how medical men were paid in England. When the system was explained to him, he asked if there could be a single Englishman in good health? "I will tell you," he said, "how I treat my physicians. I have four to whom the care of my health is confided; a certain sum is given to each, weekly; but as soon as I am ill the salaries are stopped till I am well: I need not tell you that my illnesses are not long." By this it appears that the medical care of the celestial emperor is no joke.

STATUE TO GEOFFROY ST. HILAIRE IN HIS NATIVE TOWN.—The corporation of Etampes, the birthplace of Geoffroy St. Hilaire, have resolved to do honour to the memory of the great naturalist by erecting him a statue. Although amply supported by the French Government, and by the most eminent men of their own country, the committee wish to render the monument as honourable as possible by associating in their project the scientific men of all nations. Although Geoffroy St. Hilaire was a native of France, and although his fame is one of her proudest boasts, still the committee consider that his European reputation, as a scientific naturalist, justifies such an appeal. It is one of the privileges of science that its progress does not benefit that country only in which it takes place; and is it not, therefore, proper that all, who have enjoyed the lights of genius should come forward to do homage to it? For this reason the committee, while they desire to record as among the first the homage paid by their own countrymen, appeal equally to the lovers of science of other countries whose scientific institutions have considered it an honour to number among their members the illustrious Geoffroy de St. Hilaire. Subscriptions in aid of this worthy purpose are received by the secretaries of the Academy of Sciences, Paris.

ILLEGAL PRACTICE OF PHARMACY IN FRANCE.—At the request of the Prefect of Police, and by virtue of a special warrant from the chief of the School of Pharmacy, M. Gaultier de Claubry, a professor of that school, last week entered a drug shop in the Passage Vivienne, Paris, kept by a M. Thomas. On his arrival M. Gaultier de Claubry did not find the master of the shop, but in his place a young man who had previously been a shopboy in a bazaar, and who, from the nature of his education, could possess no knowledge of the properties of medicinal substances. It was also discovered that the preparations were seriously adulterated, and that the closet for the reception of poisons, which contained some of a very active nature, not being locked, as is required by law, was open for the use of an ignorant person whose errors might have produced the most serious consequences. An immediate seizure was made of the articles in the shop, which has since remained closed. M. Thomas has also been summoned before the tribunal of Correctional Police under the act for preventing the illegal exercise of pharmacy, because he was known to have practised without a diploma, and under that for preventing the sale of badly-prepared or damaged medicines, or the keeping of poisonous substances without the security of a lock and key. M. Thomas not obeying the summons the bench condemned him to ten days' imprisonment, and to pay a fine of 100 francs (£4).—*Gazette Medicale de Paris.*—[They manage these things better in France.]

MORTALITY TABLE.

For the Week ending Saturday, August 22, 1846.

Causes of Death.	Total.	Aver 5 summers.	years.
ALL CAUSES........	902	898	968
SPECIFIED CAUSES...	901	892	961
Zymotic (or Epidemic, Endemic, and Contagious) Diseases..............	258	201	188
SPORADIC DISEASES.			
Dropsy, Cancer, and other Diseases of uncertain or variable Seat..........	105	99	104
Diseases of the Brain, Spinal Marrow, Nerves, and Senses..............	125	155	157

No. 362. SUMMARY. Sept. 5

PROGRESS OF MEDICAL SCIENCE,

INCLUDING CHEMISTRY AND PHARMACY.

France.

ACADEMY OF SCIENCES.

Meeting of August 24; M. Mathieu in the Chair.

Morphee and Pellagra, by Dr. Rendu.—During the course of a scientific mission into the interior of Brazil, M. Rendu had an opportunity of observing an endemic disease which he considers to present numerous analogies with pellagra. The disease is to be met with throughout the country from the Amazon River to the River Plate, and has even invaded French Guiana: age or sex affords no protection against it, and its appearance is not announced by any premonitory signs. On various parts of the body maculæ are observed, of different size and colour, and the diseased portions of the skin are immediately deprived of sensation, and of their exhaling properties. These tubercular productions of the cutis gradually increase in volume and acquire the dimensions of a pigeon's egg; they ulcerate in almost every instance. When the mucous membrane of the nose is attacked, the cartilages fall, the organ is deformed, and death is brought on by the progress of the disease towards the respiratory viscera. Muscular cramps, subsultus tendinum, formication of the extremities, and considerable increase of appetite, are also constant symptoms of this singular and, hitherto, constantly fatal malady. When the bodies are opened, besides the variable anatomical alterations to which may be traced the proximate cause of death, the brain, cerebellum, and spinal cord are always found in a marked state of atrophy, and floating in serous fluid proportioned in quantity to the diminution which the nervous centres have undergone The disease is attributed to the influence of heat and damp on persons whose alimentation is too much azotized. The manner in which the patients affected with "morphée" are treated in Brazil is not the least curious part of the account forwarded to the Institute by Dr. Rendu:—At Rio Janeiro the *bite of a rattlesnake* was prescribed,—and, having been *twice* repeated in the course of 24 hours, the patient died next day; *guano* has also been employed in the country, but without success. Dr. Rendu is of opinion that it is more the producing cause which should be modified, than the symptoms themselves, which appear incurable. We do not think, however, by his own account, that medicine has had a fair trial. By its causes, by several of its symptoms, and by the constancy of anatomical changes in the nervous centres, this disease, in Dr. Rendu's opinion, resembles closely pellagra, from which it differs in one essential point, viz., the disordered state of the digestive powers in pellagra, and their perfect preservation in morphée.

Hemicrania; by Dr. Auzias, Turenne.—According to the author, hemicrania is a headache resulting from pressure on the fifth pair of nerves, and particularly on its ophthalmic branch, by blood accumulated under the influence of various causes in the sinuses of the basis of the cranium, and especially in the cavernous sinus. Dr. Auzias considers that his theory is supported by the following deductions:—The ophthalmic branch and its ramifications are evidently the seat of hemicrania, and lie in the external wall of the cavernous sinus, separated from the blood by a very thin membrane, and exposed therefore to suffer compression from any unusual fulness of the sinus. Nausea and vomiting, the frequent companions of hemicrania, are explained in this theory by compression of the par vagum, in the foramen lacerum, or in the neck; distention of the vessels of the head, and obstruction of the venous circulation, are attested by the injection of the eye of the diseased side, and the swelling of the frontal veins—two habitual symptoms of hemicrania: the suffering is, besides, often arrested by bleeding at the nose, and increases with every pulsation of the carotid artery. In conclusion, M. Auzias recommends, for the treatment of hemicrania, revulsion on the digestive tube, by which the inferior cava may be disgorged sufficiently to permit the superior cava to abstract from the head the quantity of venous blood in excess. Dr. A. also recommends patients labouring under hemicrania to adopt certain positions calculated to facilitate the passage of the blood from the head.

Proportional Analysis of Ore, by M. Marguerritte.

Professor Dumas read the following report:—It is now some years since M. Thomson sought to obtain by the humid way, the equivalents of a large number of substances. His system consisted in the preparation, in known proportions, of solutions capable of acting upon each other in such a manner as to permit the chemist to ascertain the exact weights of the substances employed, no residue being left after the accomplishment of their reciprocal reactions. At a later period this method was applied by Professor Gay-Lussac to the precise measurement of silver in raw ore. For this purpose the learned professor showed it was sufficient to ascertain the volume of a solution of chloride of sodium necessary for the precipitation of a known quantity of alloy; hence the possibility of analysing with precision all these metals by special reactions of the same nature can readily be admitted. Thus M. Pelouze has lately proposed the use of a standard solution of a sulphuret for the detection of the weight of copper contained in a metallic compound. It is not, however, always easy to reduce the problem to such simple terms, viz., the determination of the quantities of an acid or of a basis neutralised by each other, or to the discovery of the quantities precipitated by the mutual reaction of two substances. The oxides of some metals form no neutral salts, or their deposition by re-agents gives rise to substances which leave some doubt upon the mind of the operator as to the exact time when they have attained the extreme limit of their action; such is the case with iron. Therefore it is that Mr. Marguerritte proposes to obtain its exact separation by an indirect method, *i. e.*, by the use of a solution capable of losing its colour when it yields oxygen to the protoxide of iron, thus converted into a peroxide. His plan rests upon the transformation of protosalts of iron into salts at the maximum of oxidation, under the influence of a standard solution of permanganate of potass. It is a known fact that salts of iron enjoy the property of discolouring the mineral chameleon, the purple colour of which returns only after the iron has been completely superoxidated. The quantity of discoloured permanganate of potass is in exact proportion with a given weight of the salt of iron, however rapid and easy the system of analysis. A known weight of ore is dissolved in muriatic acid; the solution is reduced to the minimum of oxidation with zinc; and the standard solution of permanganate of potass is then cautiously poured into the liquid until a slight colour is produced, and a simple proportion indicates the quantity of iron contained in the ore. This method is applicable to all cases, even where copper or arsenic is combined with the alloy;—they are first separated by zinc, and removed by filtration, after which the operation should be prosecuted as we have already stated. Professor Dumas concluded his report by moving that the Academy grant its fullest approbation to the new application made by M. Marguerritte of chemistry to commercial purposes." The report was unanimously adopted.

ACADEMY OF MEDICINE.

Meeting of August 25; M. Roche in the Chair.

The Plague.

After a short debate, in which M. Gérardin, M. Adelon, and M. Castel took part, and in which it was argued that the first conclusion could not be adopted by the Academy without involving debatable questions, the meeting came to a division on the conclusion of the first section of the report, viz.—"The plague not only arises spontaneously in Egypt, Syria, and Turkey, but has also been observed in several parts of the continents of Asia, Africa, and Europe."

The Academy rejected the conclusion. Ayes, 21; noes, 24 blank votes, 3.

Morbid Anatomy.

Professor Blandin presented in the name of M. Tosse, surgeon of the Hospital of Amiens, an interesting preparation of morbid anatomy, referring to the history of fractures. M. Tosse had been called upon to attend a case of deformity of the leg, consequent upon fracture. The limb was distorted to such a degree that the patient could not walk. Resection was performed, and a perfect union was obtained. M. Blandin laid before the Academy the portion of bone which had been removed, together with two casts representing the limb before and after the operation.

Professor Duméril observed that the father of the successful operator had, many years previously, obtained most satisfactory results from resection in a case of compound fracture of both legs. The cure had been so perfect that the learned professor had

seen the patient, a young lady, dance without any sort of difficulty of movement.

Professor Velpeau remarked that between the two cases a very important difference was to be noticed. In the case related by M. Duméril the operation had been performed very shortly after the occurrence of the accident; in the other instance the resection had another object, viz., to remedy a vicious consolidation of bone.

EBURNATION OF ARTICULAR SURFACES.

Professor Lesauvage, of Caen, a corresponding member of the Academy, presented two cases of eburnation of articular surfaces, resulting from inflammation of joints, and ulceration of their cartilaginous structures. The first preparation had been removed from the body of a prisoner at Bicêtre, who had died of another complaint quite foreign to the disease of the knee.

The second had been observed in the hip-joint of a man who had died from purulent absorption after amputation of the thigh, necessitated by compound fracture. The eburnation occupied the insertion of the inter-articular ligament, and the corresponding part of the head of the femur; before the fracture occurred the patient offered no symptom which might have led to a diagnosis of the alteration.

TREATMENT OF DERANGEMENT OF THE EXCRETION OF URINE, CAUSED BY HYPERTROPHY OF THE PROSTATE GLAND; BY A. MERCIER, M.D.

The retention and incontinence of urine, so frequent in old men, has been hitherto referred to paralysis of the urinary organs, resulting from the progress of age. Under the influence of this theory, stimulating preparations of all sorts, both internally and externally, have been recommended. Thus the tinct. lyttæ, blisters, injections of acids, of sulphurous and ferruginous waters, of very hot or very cold liquids, have been in turn prescribed. It is evident that any efforts directed towards the re-establishment of contractility of the bladder, when its urethral orifice is hermetically closed, must only tend to increase the local irritation. Permanent catheters left in the passage have, however, in some cases procured more than temporary relief, by the compression they exercise during a more or less prolonged period on the swellings, valves, and tumours, which obliterate to a certain extent the vesical orifice; but the continual pressure of the foreign body in the bladder inflames and ulcerates its mucous membrane, and becomes a cause of alteration of the urine; besides, the presence of the instrument in the urethra is not unfrequently productive of abscess and perforation. Whenever, therefore, it is possible to avoid leaving the sound permanently in the bladder, it is proper to employ another method of treatment. When hypertrophy of the prostate gland has been positively recognised, discutients of various kinds—such as salt water, calomel, corrosive sublimate, iodine—have been used, but with little or no benefit. Where advantageous results were obtained, it is to the *modus operandi*, and not to the drug, that the credit should return; thus Mr. Stafford has cured prostatic enlargements by the local application of iodine preparations; but it is evidently to the repeated passage of the bougie, and to its friction over the diseased parts, that the cure should, with more reason, be referred.

Dr. Physick, M. Leroy, and M. Tanchon have proposed various instruments for the purpose of pressing internally upon the neck of the bladder, without distending or irritating the urethra. The author, M. Mercier, recommends two instruments of his own construction—one a bent catheter; the other a straight one, with which compression of the neck of the bladder is produced when the distal orifice of the instrument is lowered. It has been, with some surgeons, an object to establish permanently a false passage through the prostate—a sort of artificial urethra, destined to replace the obstructed natural duct—but this method is a dangerous one, and is seldom followed with any permanent benefit. M. Civiale has proposed to place a ligature round the basis of prostatic tumours, or to tear them away: the former operation is impracticable; the second highly perilous. Excision of small tumours placed behind the vesical orifice is a safe and easier plan; but, in most cases, incision is sufficient, and never gives rise to any serious consequences. Eighteen patients have already been successfully treated by this method, and in fourteen cases the operation was called for by a more or less complete retention of urine. The muscular valves have always appeared to M. Mercier more easy to divide and to cure than the prostatic swellings. At any rate, whenever the radical cure cannot be attempted, the patient should be taught how to pass the catheter himself; this simple operation will in almost every case prevent retention of urine, and sometimes, by interfering with over-distention of the bladder, will permit that viscus to recover its contractile powers.

SOCIETY OF SURGERY.

Meeting of August 19, M. CHASSAIGNAC in the Chair.

DEBATE ON THE UTILITY OF SUBCUTANEOUS INCISIONS.

M. Berard was of opinion that an oblique subcutaneous wound was less exposed to suppuration than any other, because a more complete suppuration was thus produced between the wound and external objects. It was not so much to guard against the danger, so much dreaded a few years since, of the introduction of air, as to protect the parts against the suppurative inflammation. One of the circumstances which almost constantly ensures suppuration of the incision, was the suppuration of its orifice, and this orifice festered more readily in a direct than in an oblique wound. M. Malgaigne had objected that the longer the wound, the greater were the chances of the formation of pus. M. Berard would say, on the contrary, the longer the wound, the greater the chances of adhesion in some of its parts—adhesion which would protect the deep-seated portions.

M. Maisonneuve, agreeing in the main points with M. Berard, thought that atmospheric air penetrating into wounds was not always innocuous in contact with healthy parts. Air could do no injury, but when penetrating into contused wounds it might cause damage by the influence of its hygrometric and thermometric qualities. When any living fluid, blood for instance, was extravasated into the tissues, it was easily absorbed when not in contact with air; on the contrary, when this contact took place, the extravasated fluid lost its heat, and became a foreign body which nature threw off by suppuration. The larger the external wound, the more numerous would be the unfavourable chances; it was therefore advantageous to close the external wound, although it must be acknowledged this was not a constant guarantee against the suppuration of the deeper parts.

M. Malgaigne was surprised to hear it said that the fear of the penetration of air had not been the first cause of the introduction into surgery of subcutaneous incisions; observation had corrected this error. It was now known that the air being excluded, still pus might be formed, and adhesive inflammation take place in spite of the presence of air. Many surgeons, amongst whom were MM. Monod and Malgaigne, had rejected both the theory and the practice; others, M. Berard for instance, had rejected the theory but preserved the practice, and had adopted another explanation. As to the suppuration of deep-seated parts being the consequence of the suppuration of the orifice of a wound leading to them, this was a mere assertion devoid of proof; neither did M. Malgaigne believe that the solution of the problem could be found in the mortification of living fluids described by M. Maisonneuve. If that gentleman's theory were true, the larger the seat of a compound fracture, the less should be the fear of introduction of air; and yet we know that a compound fracture of the tibia is less dangerous than one of the femur. There is always a something which remains unknown in this difficult problem:—thus a wound interesting only the soft parts might readily heal by first intention, but when a bone was also concerned, as in compound fractures, amputation, &c., suppuration was always observed. Of these facts no theory furnished, as yet, any satisfactory explanation.

DAN. M'CARTHY, D. M. P.

Belgium.

CASE OF ATROPHY FOLLOWING AN INJURY OF THE RIGHT SUPERIOR MAXILLARY NERVE.—M. Vallez relates the following case in the "Journal de Medécine, de Chirurgie, et de Pharmacologie," published by the Society for the Promotion of the Medical and Natural Sciences, established at Brussels. The patient, a man aged forty, first consulted M. Vallez in the middle of August, 1845. In the previous month of May he had felt the power of vision in his right eye decrease progressively. A continual discharge of tears took place from it, changing after some time into a puriform discharge. At length, after the application of a poultice, the cornea burst with acute pain. From that time (about two months before he consulted M. Vallez) the globe of the eye by degrees became retracted. When M. Vallez first examined the patient the right eye appeared like an irregular piece of dirty chalk; it performed slight motions, especially when touched or uncovered; it was soft, and induced pain in the bottom of the orbit when pressed. The right side of the face was insensible when pricked with a needle, provided the instrument was not introduced more deeply than the skin. When the patient laughed his mouth was drawn to the left side, his tongue also was displaced towards the left side. His food did not present the same taste to him as before his disease; his smell and hearing were normal. His left eye was unaffected, though rather watery. M. Vallez, while endeavouring to discover the origin of this singular affection, noticed a cicatrix, two inches long, on the right cheek of the patient. This cicatrix followed a line drawn from the right ala of the nose to the lobe of the ear of the same side; it projected, and appeared white and indolent. The cheek of the same side was constantly pale; whilst the left cheek was considerably injected, and possessed its natural degree of heat. The patient stated that, while shaving, a friend had pushed his elbow, causing him to make the wound, which had been very deep, and from which a considerable quantity of blood had flowed. It took a month in healing. The wound took place in the commencement of March, and it was a month after its healing that the disease of the eye commenced.

*** Our readers are aware that section of the trifacial nerve, as performed by M. Magendie on animals in the interior of the cranium, always interferes with the nutrition of the eye on the corresponding side, and brings on, after a time, its destruction. Indeed, M. Serres, Dr. Abercrombie, Mr. Stanley, &c., have recorded cases in which the same results have followed the presence of tumours, compressing the trifacial within the cranium, and and thus altering its structure in the human subject. In these cases, however, the lesion of the trifacial was situated between the brain and the eye. Cases of amaurosis following lesions of the peripheral extremity of the nerve are also well known; such are produced by injury or contusion of the peripheral extremities of branches of the ophthalmic, situated in the temple or the eyebrow; this class of cases forms a distinct order in the description of amaurosis. We have not hitherto, however, on record any case, as far as we know, in which the nutrition of the globe of the eye has been disturbed in consequence of injury occurring to a part of the nerve placed between the eye and its peripheral extremity.

IMPERFORATE VAGINA—OPERATION PERMITTING THE PERFORMANCE OF THE SEXUAL FUNCTIONS.—Professor Kluyskens has published, in the "Annales de la Société de Médicine de Gand," the case of A. B., of Termonde, who was treated when seven years of age for an inflammation of the right kidney, which, after some time, was followed by an abundant discharge of purulent matter per urethram. At the age of eighteen menstruation had not made its appearance, although for the last fifteen months she had experienced acute pains in the abdomen, similar to those of colic. These came on at first at distant intervals, afterwards every month, and subsequently every fortnight. The abdomen was distended, the pulse small and frequent, and there were borborygmus, suppression of

the urinary excretion, and other hysterical symptoms. Opiates, antispasmodics, emmenagogues, and leeches to the inside of the thighs, were tried in succession, but with no good result. Sulphate of quinine was also prescribed, but to no purpose, under the impression of the case being one of masked intermittent fever. Weak and worn out by suffering, the patient at length decided on consulting Professor Verbuck, who suspected a malconformation of the sexual organs. The abdomen was as large as in an advanced stage of pregnancy, and a hard resisting tumour could be felt extending as high up as the umbilicus. The external parts of generation were properly formed, but there existed no trace of a vaginal opening. On passing a sound into the urethra, and then introducing the index finger into the rectum, nothing could be felt between these two organs but a thin fibrous cord, which occupied the place of the canal. There was no longer, therefore, any doubt as to the nature of the affection. It was, in fact, a congenital occlusion of the vagina. As death appeared inevitable unless operative means were had recourse to, M. Verbuck consulted Professor Kluyskens, who advised the formation of an artificial vagina. This being decided on, the operation was performed in the following manner:—A sound having been passed into the bladder, and forcibly raised towards the pubes, and the finger introduced into the rectum for the purpose of depressing it, the surgeon made a transverse incision of eight or ten lines in length between these two points, and these gradually, and with very great care—in order to avoid injuring either the urethra, the bladder, or the rectum—penetrated to the depth of three inches. At this stage of the operation no tumour could be discovered on the introduction of the finger, and at this moment of painful hesitation, one of the assistants, having probably before him the unfortunate case mentioned by De Haen, advised a curved trocar to be plunged into the uterus through the rectum, in order to evacuate this viscus and palliate the symptoms. This advice, however, was not followed, and it was decided to continue the operation, when, on extending the incision to about an inch in depth, the presence of a tumour formed by the distended uterus was ascertained; but it was evident that there existed no trace whatever of a neck or os tincæ. This was the critical moment of the operation, which was borne with great fortitude by the patient. Professor Kluyskens, after having well satisfied himself of the position of this tumour, plunged into it the point of a long-bladed bistoury, covered to the extent of two-thirds with linen, and made a large opening in it. An immediate discharge of about five pints of viscid blood, having a faint odour, took place, whereupon the distention of the abdomen subsided. Some warm water was then injected a few times into the uterus, and the patient immediately placed in a bath. About ten days afterwards inflammatory symptoms appeared, and caused a fear of an acute attack of metritis; fortunately, however, they yielded to antiphlogistic means, particularly a frequent repetition of warm baths. After some little time a gum-elastic canula was occasionally introduced into this artificial canal, and the cure was complete at the end of five weeks. Since then several years have elapsed, and the artificial canal has still existed; the patient has enjoyed good health, her menses have appeared regularly, though suddenly, and without pain; but there has existed in the intervals a rather abundant leucorrhœa. Mademoiselle A. B—— has since married, but had had no children when the above was written.

Ireland.

Treatment of Uterine Polypi and Ulceration.—Dr. Montgomery has published, in the "Dublin Quarterly Journal of Medical Science," a very interesting paper on Uterine Polypus, which was read before the Dublin Obstetrical Society. During the year 1845, Dr. Montgomery operated seven times for ordinary benign polypus, and once for a malignant polypoid growth of the cauliflower excrescence kind, viz., three times by ligature, three times by torsion, once by excision, and once by caustic. All the cases of benign polypi did well. In that of cauliflower excrescence, the operation by ligature was eminently useful, but the disease returned, and the patient refused further interference. Dr. Montgomery calls attention to the fact that polypus, even when of very small size, is frequently accompanied by ulceration of the labia of the os uteri; these ulcerations are, he believes, in general produced by the polypus, or owe their existence to its formation, rather than to the operation for its removal, which, however, may occasionally produce such an effect; they will sometimes heal without treatment on the removal of the polypus, but, as frequently, they will not: it should, therefore, be a rule to examine such cases with the speculum before they are pronounced quite well, lest the patient should only be cured of one-half her disease, and left to the consequences of the other. In the case on which Dr. Montgomery operated by excision, considerable hemorrhage took place (although the pedicle was of small size, and its division had been effected by scissors), which was arrested with difficulty. Dr. Montgomery also mentions a case in which Dr. Kennedy had seen the division by the knife, of the pedicle of a polypus, not thicker than a common quill, followed by such an amount of hemorrhage, as to endanger the patient's life. Dr. Montgomery also calls attention to the shrinking of the pedicle of a polypus of the fibrous kind, as it may be the cause of the hemorrhage which sometimes follows excision, especially of large polypi, even where the precaution has been taken of firmly tying the pedicle before dividing it. The pedicle, thus shrinking in, slips away from the ligature, which virtually becomes loose, and of course ceases to exert any pressure on the blood-vessels, which then pour out their blood, just in the same way as not unfrequently happens with the umbilical cord of the new-born infant. Two cases in which this happened have come under Dr. Montgomery's notice, in one of which the patient died within a few hours after the division of the pedicle; although, from the skill and experience of the operator, Dr. M. is persuaded that every requisite precaution was taken. Dr. Montgomery has altogether operated on thirty instances of this disease; out of which the removal of the tumour was effected,—in three cases by excision, two by caustic, nine by torsion, one by ergot, and fifteen by ligature. In two other cases the polypus was destroyed accidentally,—once during labour, and once by the action of the expanding speculum. The instrument which Dr. Montgomery always used for applying the ligature is the double moveable canula of Niessens, and he has never yet met with a case which was not manageable by its means. The ligature which he prefers to all others, and which he always uses, is silk salmon fishing-line, prepared by soaking it in linseed oil, in which state it combines the necessary qualities of great strength, perfect pliability and softness, and remaining unaffected by moisture. The forceps, which are very useful for twisting off small polypi, consist of a straight stem about eight inches long, set in a handle; at the extremity of the stem are two short spring-blades, with serrated tips, upon which slides a brace moveable from the handle, by which they are easily pressed firmly together, and made to grasp very securely any object caught between them. Of the thirty cases operated on, one only terminated fatally, which, considering the wretched condition in which many of the patients were at the time of the operation, and some of them for months or years before it, is an encouraging and satisfactory result; but it should not be forgotten that the cure of polypus of long standing, and accompanied with large discharges, is, under certain circumstances, associated with a risk which claims careful consideration. Experience shows, that if a woman has for many years laboured under polypus, with constant and large discharges, and if she be naturally of a full habit and inclined to good living, and especially if she be of such an age that, after the removal of the disease, menstruation is not likely to recur, there will be danger of determination to the head, as in other cases of suddenly-suppressed discharges; and it will, therefore, be the duty of the medical attendant to prescribe such a carefully-regulated system of diet and medicine as he will deem best suited to prevent the occurrence of plethora and cerebral congestion, which Dr. Montgomery has seen take place fatally, under such a combination of circumstances. From Dr. Montgomery's cases and remarks it may be collected:—That very small uterine polypi, or polypoid excrescences, are of frequent occurrence. That they are often not discoverable by touch alone, and so escape notice. That they may even elude detection with the speculum, especially if the instrument used is not capable of separating the lips of the os uteri. That they are a common cause of ulceration and menorrhagia, one or both; the cure of which requires, as a preliminary step, the removal of the polypus. That while thus, on the one hand, a small polypus may escape detection, there is, on the other hand, a peculiar condition of the anterior lip of the os uteri liable to be mistaken for a polypus, and requiring a long time for its removal. That the very small polypus of the os uteri is seldom solitary, and, in common with polypi of other kinds, is very often combined with other diseases of the uterus, especially with fibrous tumour. That these small polypi of the os uteri, when occurring in women of advanced age, especially if they are of the vesicular kind, are often the precursors of a malignant form of uterine disease. That polypus being very frequently accompanied by ulceration of the os and cervix uteri, and its concomitant pain and structural alteration, the symptoms are occasionally mistaken for those of cancer; which error is most likely to be committed if an examination should happen to be made just when a polypus of rather large size is passing through, but still engaged in, and distending the os uteri. That in cases of larger-sized polypi, ligature is the means most generally eligible, as being safer than excision, though not so expeditious; its application having, in general, the immediate effect of restraining the morbid discharges, and alleviating other symptoms, and ultimately curing the disease. That polypi and polypoid excrescences of small size are best removed by torsion; or in some instances their destruction may be conveniently effected by caustic. That with large polypi torsion is unsafe and should not be attempted. That even with a polypus of small bulk, and slender pedicle, excision is not free from the risk of troublesome hemorrhage, while with those of large size there is great reason to apprehend such an occurrence taking place to a very dangerous degree, even though the precaution may have been taken of firmly constricting the pedicle with a ligature previous to its division. That in ordinary cases of benign polypus, when no other disease exists in the uterus, the removal of the tumour by ligature, or other suitable means, is, in the vast majority of cases, completely successful, even under circumstances apparently quite hopeless. That in malignant growths, such as cauliflower excrescence, removal by ligature will sometimes effect a complete cure; and that, where the success is not so decided, much good may be done by the operation. That the situation from which a polypus springs makes a considerable difference in the symptoms which it produces: a polypus of the lip of the os uteri giving rise to fewer symptoms and much less discharge than one of very inferior size growing from any part within the os uteri. That a polypus of only moderate size growing from the lip of the os uteri is not likely to interfere injuriously with gestation or delivery, and its removal may be effected by, or as a consequence of, the pressure which it sustains during the expulsion of the child. That if a polypus, already detached, be too large to pass readily out of the vagina, it ought not to be allowed to remain there; but should be removed with the least possible delay, as its putrefaction may be attended with very unpleasant consequences. That a fibrous tumour originally formed in the substance of the uterus may thence descend, pass through the os uteri, and form an ordinary pediculated polypus in the vagina. That in the unimpregnated state of the uterus, this change will be effected gradually, and in general very slowly; but that, should pregnancy occur, the descent and expulsion of the tumour may take place quickly under the expulsive action of labour. That a polypus, even of large size, may thus make its appearance for the first time, immediately after delivery, no suspicion having

been previously entertained of its existence. That the cure of long-standing polypus, with large discharges, is liable to be followed by a condition of the system requiring precautions against determination to the head.

A Course of Lectures on Diseases of the Skin.

By JAMES STARTIN, Esq., Surgeon to the London Cutaneous Institution.

LECTURE XXII.

APHTHA.

According to Willan and others.

GENUS.	SPECIES.
Aphtha.	A. Lactantium.
	A Adultorum.
	A. Anginosa.

As proposed by Startin.

GENUS AND SPECIES.

APHTHA.		
A. Alba vel simplex.	Localis.	Sparsa.
A. Luteola.		Conferta.
A. Ulcerosa.	Pluri-localis	Inveterata.
A. Gangrenosa.		

Hitherto, gentlemen, these lectures on the chronic affections of the human dermis have been demonstrative, from the circumstance of the diseases described being placed on the surface of the body, and thus giving access to the handicraft of the modeller. Aphtha (or the thrush, as the affection is popularly called), to which I have now to request your attention, from its constant and invariable situation on those inflected portions of the skin which line the different openings of the body, must depend entirely upon my descriptive powers—a manifest disadvantage, but one that is insuperable, from the position of the disease.

The thrush may be an idiopathic or symptomatic manifestation: in the former case, it is, I believe, confined to infant life; in the latter, adults may be the subjects of its attacks. In every instance the mouth is to be regarded as the chief seat of the disease, though other internal parts, even to the extent of the whole intestinal canal, may in severe and rare cases be more or less implicated: from this cause aphtha has been discarded from the consideration of many writers on diseases of the skin, as not appertaining to that department of medicine; Willan, however, included the complaint in his erudite dissertation, and I am content to follow, humbly enough, in the footsteps of so able and excellent a master. I shall, therefore define *aphtha* to be an eruptive disease, on those inflected portions of the human skin lining the mouth and other passages, which consists primarily in an erythematous inflammation of the part affected, and is followed by the appearance of small white or pearl-coloured and sometimes yellowish vesicles, that quickly break and demonstrate white or yellowish depositions, resembling milk curd or false membranes on the affected parts, the morbid phenomena disappearing, and the diseased portions of the inflected skin resuming their healthy aspect, after an uncertain but brief period, though occasionally the aphtha may terminate in ulcerations and gangrene.

This exceedingly common disease, at least during the first periods of human existence—that of lactation—is very constantly, from its usually unimportant nature, delivered over to the cares of the nurse, by the consent of both parent and medical attendant; it is only in its severe manifestations that it claims the assistance of our profession. Its origin in most instances may be traced to some few days' previous indisposition; in fact, it may be said in this respect to resemble herpes of the lips, as described in the last lecture, and from this complaint, when it extends within any openings of the body, aphtha in its early stages is not to be distinguished; the difference, however, becomes obvious enough as the affection assumes the characteristic which I have endeavoured to signalize in its arrangement on the chart, to which I beg to direct your attention. You will perceive that I have again ventured to deviate from the established routine; this, as in all former instances, has arisen, not from a desire to introduce novel views, but from a wish to bring forward a classification of the subject, which in itself might be a sort of language indicative of the precise position and manifestations of the disease. Thus the GENUS APHTHA is comprised under four species, named from their manifestations: — *A. alba vel simplex*, white or simple aphtha; *A. luteola*, yellowish aphtha; *A. ulcerosa*, ulcerated aphtha; and *A gangrenosa*, gangrenous aphtha,—all of which may have a local or more extensive existence, and appear in a scattered, confluent, or inveterate form or variety.

I shall detain you but a very short time with a brief description of these species. *A. simplex* or *alba*, whether idiopathic or symptomatic, is manifested by more or less inflammation, heat, and redness of the lining of the lips, cheeks, or fauces, and of the skin of the tongue, on all or any one of which parts the complaint may be situated; to this inflammation succeeds an eruption of small flattened vesicles filled with a milky fluid, which gives them a white or pearly appearance. A few hours is mostly the duration of these vesicles, when they break, leaving a superficial excoriation of greater or less extent according as the eruption has been scattered or confluent; this diseased surface next becomes covered with coagulated lymph, giving the appearance either of curd or false membrane, as mentioned in the definition; so close is the first resemblance in some cases that the aphtha of infants has been deemed by certain authors to have its origin from allowing the child to *sleep* with a portion of milk in its mouth unswallowed. I need scarcely remark that this is an absurd supposition, arising in all probability from a resemblance found to the appearances described, added to an inaccurate examination of the affected parts; for it is certain that most babes are found to sleep at the breast under the circumstances specified, and this without the least derangement of their health The whole progress of aphtha alba does not usually continue more than ten days or a fortnight before its final disappearance; and perhaps, in every case, if its commencement be attentively watched, a few days' indisposition or more or less general disorder of the system will be found to precede it, acidity of the primæ viæ being constantly a concomitant symptom. It is also worthy of notice that the eruptions of the vesicles are successive, commencing in the same manner whether the complaint be idiopathic or symptomatic, and that every part of the mouth and fauces, or the whole alimentary canal, may be invaded—the disease showing itself in some new situation as the healing process is completed on that it lately occupied.

This constitutes the inveterate form of the malady, which, when fairly established, must be referred to the next species designated on the chart *A. luteola*, which, on its first appearance, does not differ in any important particular from the simple species of the disease; but the vesicles rapidly become confluent and assume a yellowish hue, extending all over the mouth and into the pharynx, œsophagus, and probably through the alimentary canal, as vomiting and diarrhœa are the very constant attendants on the disease.

At the close of bilious fevers in the adult this state of things is not unfrequently witnessed, as also after erysipelas, measles, &c.; and it is the pest of the wards of hospitals appropriated to sick children and lying-in women, who are closely congregated and breathe a vitiated atmosphere. In the asylum for foundlings, the ("Enfans Trouvés") and the hospital for sick children ("Enfans Malades"), at Paris, this form of aphtha is to be witnessed in all its malignity, and often decimates its victims. It would appear to be epidemic in such localities; and authorities of repute are not wanting who consider it, under such circumstances, contagious or infectious, or both. The vesicles of aphtha luteola are much more apt to degenerate into ulcerations and sloughing or gangrene, than in the white species I have already described; it is also to be very generally regarded as a symptomatic affection supervening for the most part in children badly nourished and nursed; or in adults who have been reduced by lingering diseases, or by long courses of medicine. In fevers it would appear occasionally to be deservedly considered as a *critical eruption*, which, when of a livid or black hue (the *aphtha maligna* of Sauvages), is to be deemed unfavourable, and *vice versa*. The surface of the body is not unfrequently affected with petechiæ or miliary eruptions in these severe cases of aphtha; and marasmus, or cachexy of some kind, is its usual complication.

The third and fourth species of aphtha on the chart (*A. ulcerosa* and *A. gangrenosa*) are merely terminations of the last-mentioned or first-described species; their name sufficiently indicates their nature, and is adopted only for the sake of precision in describing the particular stage of the complaint. I must observe, however, that ulcerations are by no means common in aphtha, when uncomplicated with syphilis or scrofula, and that gangrene is still less so; when they do occur so as to constitute *A. ulcerosa*, the disease runs through its vesicular form in the usual manner, though a greater degree of attendant erythema or inflammation may be observed; and in the place of a superficial layer of coagulable lymph covering the spots occupied by the eruption, a tenacious slough, of a yellow or darker hue, is witnessed, which extends more or less deeply into the parts on which it is situated, and enlarges laterally much beyond the space it first attacked. These sloughs separate slowly, leaving ulcers of irregular depths, filled with loose granulations, which, as the parties affected are in bad health, heal slowly, and are very prone to bleed or assume a black gangrenous aspect (*A. gangrenosa*), which may resist all measures for its relief: a circumstance perchance less owing to the nature than to the position of the disease, which prevents or impedes deglutition, so that food or medicine can be administered only under the most disadvantageous circumstances, or not at all.

From the foregoing remarks I should hope no difficulty could occur in the diagnosis of aphtha, which indeed resembles no other disease when situated in the mouth; but I have seen this complaint, within and around the margin of the anus and pudendum, both in children and adults, present an aspect which might occasion it to be mistaken for eczema; the constitutional symptoms, and particularly the coexistence of the aphtha in the mouth, will furnish the necessary distinctions between one case and the other.

With respect to the treatment necessary, soothing palliative measures are the only local indications; to which, for the purpose of cleansing the parts, slight astringent remedies may be superadded, the best being the mel. boracis of the nursery, or raspberry vinegar properly diluted. In cases of gangrene more powerful remedies may be required, as advised for rupia escharotica; nitric acid, more or less diluted, and the oxymel æruginis of the old Pharmacopœia, being required. I have also found a wash composed of sesquicarbonate of soda and a few grains of borax, suspended in a little yolk of egg and water, in the proportion of four or five grains of soda and one or two of borax to each ounce of fluid, very useful where much acidity was evident either in the breath or secretions—a fact easily ascertainable by the use of a slip of litmus paper. The internal remedies should be chiefly alkaline, as mildly aperient magnesia, soda, or liq. potassæ combined with rhubarb; or infusion of senna, with the addition of a little hyoscyamus, syrup of poppies, or laudanum, being mostly required. Of course each case will call for some slight deviation from any given rule, and the advanced or inveterate forms of aphtha, dependent on constitutional causes, must be treated according to general principles, which I have no need to detail. Diarrhœa and vomiting, so frequently the attendants on these cases, I have found more readily restrained by the compound powder of kino, administered in doses proportioned to the age and condition of the patient, both by the mouth and by way of enema, than by any other remedy; and I have constantly experienced the advantage of using the blanket bath, as it has been termed, to the infantile sufferers from this disease, where visceral disorder may be existing—the determination to the skin produced by this simple agent being such as to render it a very important and always available means in the treatment of many

internal maladies; indeed, in the hands of *another Priessnitz*, it might, like hydropathy, become a panacea for all the ills that flesh is heir to, without half the inconvenience, and with all the benefit, attached to that extraordinary revival by a German uneducated peasant, of disused medical expedients.

The mode I usually recommend in applying the "*blanket bath*," is to wring a new blanket out of water at 98 to 100 degrees of Fahrenheit, until no more liquid can be expressed by using moderate force; this is to be done at the bedside of the patient, who lies in his night-dress upon a double dry blanket, ready to be enveloped in that which has been prepared, the steaming hot woollen is next passed around his person, and the wh[illegible] covered by folding the double dry blanket in such a manner as to leave room for free inspiration only, whilst all moisture is kept from the bed. I can assure you that, if this simple expedient were more generally practised, the expensive and cumbersome warm and vapour baths, in present use, might be almost abolished, as it will be surprising to those who have never witnessed the process that so considerable a degree of heat can be thus applied, and kept up, with little or comparative fatigue to the patient.

I shall not longer detain you by a recital of any case of aphtha, as I have entered so fully into the remedial measures to be adopted; and I will not waste your time by a recapitulation of the application of general principles to any selected instance of so common an affection, in its simple and ordinary forms, but rather fill up that portion of the allotted time which to-day remains to us by briefly reviewing the series of chronic cutaneous diseases to which the complaint last under our notice would seem to form a break or boundary (inasmuch as it is the last to be mentioned, having the *constant* distinctive marks of eruptions attended with discharges,) before we enter upon the consideration of the rashes, which have but a slender connection, either apparent or real, with those maladies which have hitherto engrossed our attention.

It will have been observed by those who have done me the honour of attending these lectures, that the diseases we have considered, like the *beau-idéal* of a sliding scale, so often adverted to in modern times, have appeared progressively to lapse one into the other; the precise boundary line, where one ended and the other began, either as a distinct genus or some one individual variety, being as undefinable as the colours in a prism. Thus, if I briefly recapitulate, we have seen, that *lepra*, *psoriasis*, and *pityriasis* are nearly identical affections, both in their nature and treatment; that pityriasis alphos congenita, a species of the last disease, is the connecting link with *ichthyosis simplex*, which again becomes [illegible]he bond of union between that complaint and [illegible]onic *impetigo* and *eczema*; the latter of which diseases occasionally runs into *lichen* or *strophulus*, both of which after terminate in *prurigo*, and sometimes in *porrigo*. The next affection we then arrive at is *scabies*, which may assume the type of nearly all the preceding genera, or some of their varieties; indeed nearly all the appearances assumed by chronic inflammations of the skin may be simulated by this complaint, which has been demonstrated to arise from a single source of irritation produced by the small insect entomologists have designated the *acarus scabiei*. *Acne* and *sycosis*, the next maladies which engaged our notice, it will be remembered, resembled scabies in the presence of a microscopic animalcule, the *acarus folliculorum*, whilst they have also a marked similarity in appearance to some varieties of impetigo or porrigo; and in a species of sycosis, attended with indurations and ulcerations, (sycosis ulcerata), a resemblance to the next mentioned diseases (*ecthyma* and *rupia*) may be traced, which maladies in their vesicular stages would seem to lapse into *pompholyx* or *pemphigus*; and these again merge into *miliaria* or *sudamina*. The next diseases on our chart, *herpes* and *aphtha*, furnish a striking group, which, whilst resembling some varieties of the pemphigus genus, yet are closely connected together in the different phases of their existence, as also in their nature and in the treatment required.

In illustration of what I have now said in so many words, I have only to point to the waxen models arranged on the table before you, in the series and order mentioned; and I beg you will observe that these are no pictures made up for effect, in which often the imagination of the artist and the vivid tints of his pencil seem to vie with each other in their attempts to pictorialize nature; but that they are faithful casts from patients attending this institution whose diseases you have constantly had the opportunity of witnessing and comparing with their waxen representations; and I think, in the plurality of examples, you have also seen the case when a cure has been accomplished. When such a tableau from the book of life as this is spread before you, how easy appears the lesson to be learned from it, and how futile the doctrines of those dermatologists who would found a knowledge of cutaneous diseases either upon the scales, vesicles, pustules, &c., apparent during some stage or other of the complaints they describe; as also of those authors who have founded their arrangements upon the complex anatomical structure of the skin, which I do not recollect as furnishing a single example of uncombined inflammation, solely affecting that portion of the dermis on which their nomenclature, arrangement, and treatment of its diseases have been based. But I have now said enough, gentlemen, in ratification of the promise given at the last lecture, to show you the grounds upon which I have introduced the practical divisions proposed in this still complicated subject, whilst I have assigned a reason for the arrangement observed which I trust you will allow has been influenced by practical considerations, not only as regards the appearance of the several diseases, but also as respects their therapeutic management.

The diseases of the cutaneous surface that I intend shall next engross our attention—*urticaria*, *roseola*, *œdema*, and *erysipelas*—form, as will be seen, a second series, or group apart, having but little traceable affinity with any of the foregoing affections—that is to say, when observed separately from any accidental complications with the diseases with which a comparison may be instituted. Throughout the whole of this group you will look in vain for abnormal products of inflammatory action; that is to say, for *scales*, *pimples*, *pustules*, or *crusts*; but, instead, you will commonly witness the more ordinary consequences of common inflammation, *heat*, *redness*, and *swelling*, in most instances ending in resolution as it is termed, but occasionally in the two last-mentioned genera, manifesting suppuration and the other usual results of the inordinate actions of the vessels of the part. May I beg that you will not forget the distinction I have here thus ventured to make, not only that you may better understand my future remarks, but also that they may assist you in directing your diagnosis and treatment of the diseases we have hitherto considered; for you will have observed that not only does each complaint, as it were, lapse into that which follows it, but that the therapeutic management of the two affections becomes identical in some one stage of their existence.

I shall conclude these observations, gentlemen, by the announcement that next week I purpose giving you a description of the first-mentioned disease of the new series before mentioned, which is known by the designation of *Urticaria*, or the nettle-rash. I beg you will not leave the room, however, without taking a parting glance of the models we have just rapidly reviewed, if only to satisfy yourselves that as far as they are concerned my observations have ocular demonstration and seeming truth on their side.

A serious disease, which rages at present among children, has within a few weeks made frightful ravages at Orleans. The ordinary degree of mortality of children is at the utmost eight weekly, but since the middle of July this mortality has increased in an alarming degree. From the 10th to the 17th July, 15 children under seven years of age died; from the 17th to the 24th, 17; from the 24th to the 31st, 18; from the 1st Aug. to the 7th, 21; and from the 7th to the 14th the alarming number of 30 deaths occurred.

The Nature, Causes, and Treatment of Mental Diseases.

By M. PINEL, M.D., Member of the Academy of Medicine, formerly Physician to the Bicêtre and Salpêtrière Asylums, Author of the "Traité Médico-Philosophique sur l'Aliénation Mentale," "Médicine Clinique," "Nosographie Philosophique," &c. &c. Translated, with Notes, Illustrative of some important Doctrines in Physiology, Phrenology, and Moral Education,

BY DR. COSTELLO,

Principal of Wyke House Asylum, Editor of the Cyclopedia of Practical Surgery, &c.

TREATMENT OF CEREBRAL DISEASES.

The treatment of cerebral diseases is divided into the therapeutic, moral, and hygienic. The therapeutic comprehends all medication calculated to combat diseases of the brain, especially at their commencement, to prevent their passing into incurability, and to the fatal complications that are soon superadded; and to discover the best indications of cure of their numerous and formidable symptoms. This treatment must be conducted with greater activity than has been usually employed hitherto, if we mean to prevent almost all the diseases of the brain from degenerating into incurable alterations and complications.

The functional or moral treatment, or the treatment of ideas by other ideas and emotions, is applied with success to all cases of chronic and partial delirium; to monomanias of superstition or vanity, in which the brain, having experienced some slight lesion at a former period, continues to *unreason* through the mere force of habit, or for want of occupation. Patients of this kind are as frequent in crowded asylums as in the independent classes of society.

The hygienic treatment especially concerns the insane whose disease imposes the necessity of complete isolation—those, in a word, who require to be placed in the material conditions most favourable to their position and interests; and hence the necessity of taking hygienic rules into consideration as regards the plan and division of the buildings, and their special appropriation to the paralytic, epileptic, as well as in reference to diet, exercise by labour, and the rules of administration by which establishments for the reception of the insane ought to be governed.

Therapeutic Treatment.

In order to treat a disease methodically it is necessary to know its seat and nature, to consider the mode of action of its causes, and to take into account the individual dispositions as to age, sex, and constitution.

At the present day, when the most searching investigations are made after pathological data, an empirical medication—that is, a provisional medication of symptoms—loses credit more and more. It is felt that we must not stop short at the secondary effects, but that we must attack the mischief at its source, and, in the cases where our knowledge does not yet enable us to act rationally, that we must order our conduct according to the rules of prudence, and above all that we are not to incur the risk of employing remedies more dangerous than the disease itself.

If, therefore, it be useful in the first instance to know the seat of a disease, it is not less so to be able to appreciate the mode of alteration, the diseased state of the organ, with a view to employing the best means for its cure. These principles are of the highest importance in their application to the treatment for cerebral affections; and our action should be directed not so much to the general symptoms as to the anatomical charac[illegible] which the diseases present. In all morbid a[illegible]s the general characters belong to constant ty[illegible] which are almost always the same whatever may be their seat, and in which the curative indications require almost always the same order of means. [illegible]s, the alterations of the brain are observed under two grand general forms, the acute and chronic. It is in these two states that we have to consider them, applying to the different affections which constitute them the best and most direct therapeutic means.

We shall, therefore, have to examine in succession the numerous cerebral affections that present

themselves with characters of inflammatory irritation, and to point out the treatment that seems to us most appropriate to each of them.

In this first form, which comprehends the commencement of almost all cerebral affections, two general but opposite indications present themselves —the plethoric state, or state of hyperemia; and the state of debility, anemia, or atony.

The plenitude of the sanguineous system is very frequent in acute diseases of the brain; young persons, naturally vigorous and sanguine, and women at the critical age, are very prone to these affections. Hyperemia is recognised by the fulness and frequency of the pulse, by a general sense of weight, and by injection and swelling of the superficial veins. But what is very remarkable, confirmed as it has been by numberless observations, is, that this excess of blood often, instead of augmenting the acuteness of the cerebral symptoms, seems to still and calm them. Although the curative indication be to unload the sanguineous system, recourse must be had to depletion with extreme reserve. I have seen at the Salpetriere females, who had been treated in other hospitals for a passing delirium, brought in in the state of furor from the abundant blood-lettings that had been employed.

The quantity of blood to be abstracted at one or two bleedings is a matter of importance, and must be determined by several circumstances that call for the medical man's best attention. He must take into account the strength and age, judging by the effect of the first bleeding whether a second ought to be had recourse to; in females, who almost always experience a suppression in such attacks, leeches should be employed, or the vein of the foot opened. We often find that the only effect of the bleedings is to diminish the state of hyperemia, and that the intellectual disturbance persists with the same degree of intensity notwithstanding. As long as the hyperemic state continues, tepid bathing ought to be avoided, as it is apt to produce congestion in the head or lungs.

Anemic debility is characterised by paleness, emaciations, general weakness, and frequent small pulse; notwithstanding this asthenic state, the cerebral symptoms exhibit extreme violence, or the delirium is calm with continual loquacity. This febrile anemia arises from various causes. Sometimes it begins with the cerebral affection, or even precedes it, as is the case when it occurs in persons who fall slowly into a state of destitution, or who refuse food, or are addicted to masturbation; sometimes it is the consequence of an over severe antiphlogistic treatment.

The causes and effects are here so evident that the necessity of restoring the strength, of giving new energy to the organs, and of obviating debility becomes manifest. Persons in whom anemia is a consequence of destitution and want of food, generally get well rapidly; with a gradually-restored alimentation, and cleanliness in all that surrounds them, strength is soon recovered, and the brain, like the rest of the organism, resumes the full exercise of its functions. When the anemia is the consequence of too abundant bleeding, recovery is slower and more difficult; the patients remain for a long time pale, languid, and listless, and chronic delirium or dementy almost always follows the treatment employed. Their food should be substantial and abundant, frequently given, and in small quantities; and tonic medicines, more especially preparations of iron, will be proper. When the anemia originates in masturbation it is extremely difficult to cure, especially in women; some of them addict themselves to it with incredible fury, and the inevitable consequence of the fatal habit is demency, marasm, and phthisis. The strait waistcoat will answer for prevention in males, but women have a thousand ways of procuring the excitement by friction. The best thing we can do is to combat the irritation of the genital organs by warm baths, cooling drinks, and, above all, by bodily exercise pushed to a degree of fatigue.

After these general indications, derived from the state of strength or debility of the patient, we must discover the therapeutic indications which each disease presents considered by itself.

Acute delirium being generally of short duration, its cure is often spontaneous, or may be promoted by rest and regimen only. But when the symptoms are more severe, large bleedings must be employed, together with counter-irritation to the feet, abundant diluents, and vomiting and purging may also be necessary. In delirium from intemperance in drink, coffee, ether, spirit of ammonia in doses of six or twelve drops, are given with success; the mindererus' spirit may be used instead of the spirit of ammonia, as it can be given in larger doses. As delirium is always an unfavourable predisposition as regards relapse, as well as the development of other more serious affections of the brain, we must not hesitate to adopt a more protracted and severe treatment than the transient nature of the delirium requires.

Mania, Maniacal Furor.—In a physiological point of view, one might suppose that emissions of blood would at once disgongest the brain, and calm the symptoms. When amendment is so procured, it lasts but a short time, and the symptoms of excitement recur almost always. Recourse must be had to sanguineous evacuations only in the cases manifestly requiring it—when the symptoms of congestion are obvious, the face being flushed, and the pulse hard and frequent. In insane females leeches may be applied, when the catamenia are suppressed, to the thighs at the approach of the menstrual period; and the more so, as there is at this time a general exacerbation of the symptoms. The mode of letting blood may be varied: at the commencement, bleeding at the arm, jugular vein, or temporal artery, ought to be preferred; when the disease has lasted for some time, blood will be best abstracted by leeches, especially when the patient is much weakened, as well as by cupping at the nape, on the thighs, or over the region of the heart.

To assist the effect of blood-letting, prolonged tepid baths may be advantageously employed, the head being, at the same, kept cool with cold water applied by aspersion or by means of a wet napkin. Cold baths and douches may also be used, but with the precaution which the state of important organs may require, and as a means of intimidation and discipline. The female patients support the cold douche better than the males. It should not, however, be continued beyond a minute or two, as it causes great suffering to some patients, and if prolonged may give rise to pulmonary or intestinal congestion. Good effects are obtained from pouring a slender jet of water on the head, or by directing it drop by drop, the patient being properly secured in bed. The application of ice also is an excellent means of calming cerebral irritation.

From remote antiquity it has been observed that when diarrhœa takes place during an attack of mania, it produces a very favourable effect on the disease; this suggested the propriety of employing purgatives. In this respect hellebore has been for ages regarded almost as a specific. This violent purgative, however, is now no longer employed. Purgatives may be employed to act at once by a single dose, or in small doses at short intervals; calomel or croton oil answer very well. In acute mania, active remedies require to be used with circumspection, as the intestinal mucous membrane then shares in the general susceptibility. It is only when the nervous action is suspended or abolished that we act more boldly. Cooling diluents, as the decoction of chicory, whey, emulsions, decoction of tamarinds, castor oil, and tartar emetic in small doses administered in gum-water, are in addition the best means to obtain a sufficient revulsion.

Tartar emetic has been highly extolled, and I have employed it often in large doses at the Bicêtre without producing any remarkable effect, even in the dose of twelve grains, and it produced neither stools nor vomiting. The cases in which it has been most useful are those of slight melancholia, or hysteria in nervous women; in small doses it gives rise to obscure, continual perturbations, which are always followed by amendment.

Camphor has been employed in large doses by Bosquillon at the Hotel-Dieu, conjointly with blood-letting unstinted, but without any better success than that obtained by other modes of treatment. Opium, which excites more than it alms, as well as calomel, so much employed in England and America, have also been favourably spoke of. As means of action against the organic cause that gives rise to the acute symptoms in the brain, all these remedies cannot be regarded as very rational.

What we should aim chiefly at favouring in maniaure, cutaneous eruptions, diarrhœa, menstruation, hemorrhoids, perspirations,—in a word, all physiological derivations which must of necessity influence the state of the brain. It is also in this view that exutories are useful towards the decline of the attack, and that the suppuration should be kept up abundantly and for a long time. Large blisters to the back will be found an equivalent for critical evacuations that are too long retarded.

When the patient has illusions, we must first ascertain if the organ, the seat of them, be healthy, as they may yield to treatment applied to the organ itself; in illusions of hearing, small plugs of cotton, powdered with caustic potass or moistened with laudanum, are employed successfully; we may act even still more efficaciously by applying cupping glasses on the mastoid process. In illusions of sight, we can act efficaciously on the optic tracts by small doses of belladonna, graduating the dose from a quarter to half a grain: larger doses would give rise to false perceptions of sight, even in persons in perfect health.

Sanguineous Congestion.—It is in the state of congestion, more particularly, that large blood-lettings produce the happiest effects, and may alone dispel, at once, headache, vertigo, noises in the ears, and numbness in the limbs. When the congestion is extreme this will not always be the case, and often, after repeated large bleedings, the symptoms are in no way abated, or, if they cease for awhile, it is only to return with greater intensity. We should prefer at all events general bleeding to leeching, unless particular indications require an application of leeches to the neck, spine, or anus.

In the first stage of insanity there is a cerebral irritation which is characterized by injection of the capillaries of the face, eyes, and even the scalp; by the swelling of the veins of the neck (the jugulars are sometimes enormous) by the throbbing of the carotids and temporals, and by great heat in the head. This cerebral congestion is particularly observed in the maniacal, monomaniacal, melancholic, and at the commencement of general paralysis. In these cases, as in all congestions, we must combat the cerebral irritation, by preventing a too great flow of blood to the head, and by exciting, by means of derivatives, an irritation or fresh secretions in a distant organ: derivatives, combined with the application of ice on the head, effect this purpose. The intestinal canal will be excited by purgatives, continued for ten, fifteen, or twenty days. Tartar emetic in the dose of one or two grains, in barley-water, chicory-water, or whey, is active without being injurious; it nauseates the stomach, while it stimulates the rest of the intestinal canal. Calomel in small doses possesses the same advantage, but it readily produces salivation in some persons. In extreme cases, drastics may be had recourse to. If the cerebral irritation persist, after the continued employment of these means, one or two blisters should be applied to the arms, legs, and, more rarely, to the nucha.

Cerebral Inflammation.—It is necessary to unload the vessels of the brain by the application of leeches and cupping at the neck, behind the ears, the temples, and the nucha; bleeding at the temporal or the jugular, if the agitation of the patient allow of its being practised, is also always useful. This mode of evacuation is preferable to general bleeding, which, however, may be had recourse to with advantage in some cases. When we have thus subdued the phenomena of reaction, by a more or less considerable abstraction of blood, we must have recourse to cold applied with precaution to the head, bearing in mind that it may be productive of two evils: when applied before blood-letting, it produces a reaction so violent that it can no longer be subdued; and when too late, the patient falls into a fatal collapse. Several methods are made use of for this purpose; pounded ice is put into a bladder, so that the patient may not be incommoded by its weight or

bulk; it should remain applied for a long time in order to produce a salutary effect. Some patients are painfully affected by the application, and we should persevere notwithstanding for some time, as the impression may not continue; if it should, as will be evinced by the cries, agitation, and suffocation of the patient, it must be abandoned as too painful; and in such a case, far from being beneficial, would only aggravate the mischief. Affusions of cold water at short intervals may also be employed, or a continuous current at the ordinary temperature may be established. In all these modes of employing cold water, care must be taken that it does not wet the chest and produce a fatal chill.

The use of revulsives requires the same precaution, and they must be employed only at certain stages of the cerebral inflammation. Their success can only be reckoned on when the general excitement is calmed; it often happens that some patients cannot bear them on the skin, and in such cases their application is followed by a general exacerbation of the symptoms. Andral thinks we ought to be very sparing of revulsives in encephalitis, and that they have no real power until coma supervenes and the general sensibility begins to be blunted. The same objections do not apply to the intestinal canal; here derivatives are always attended with good effects, except in the case where the digestive organs are affected by some morbid alteration. This opinion as to the preference to be accorded to strong purgatives is even more strongly insisted upon by Abercrombie, and he advocates especially the use of croton oil.

It has been stated that in inflammation of the brain, mercurials possessed an all but specific action; without sharing in this opinion, they may be usefully employed, either internally or by friction. We think, however, that their action as purgatives is the one most to be relied on.

Tetanus—The treatment of tetanus has varied with the ideas entertained as to the nature of the disease. We regard it as one of the symptoms of the most acute period of inflammation of the brain, when this inflammation penetrates into the motory fasciculi of the brain. We are then no longer surprised at the profuse blood-lettings resorted to by those physicians who consider tetanus to be an inflammation: several cases so treated have been cured. M. Lepelletier, by abstracting twelve lbs. of blood at six bleedings, cured a patient labouring under tetanus. M. Martin relates several cases cured in the same way; he placed the patient in a warm bath, where he was kept two hours, and three ounces of blood were taken each hour. In Lisfranc's case, in the space of nineteen days, he bled eight times, abstracting at each about four palettes; and during the same period he applied 722 leeches all along the spine, with the exception of fifty that were applied to the epigastrium.

Andral, who records these cases, freely admits that we must resort to the most rigorous antiphlogistic treatment, and that after bleeding, generally, we are to limit the application of leeches to the spine, but that we are to extend it to the nucha, the jaws, and, in the case of an amputation or wound, to it also.

The value of narcotics has been much insisted on; if success has been obtained through the use of them, the tetanus must have been very slight; they may, however, be used as adjuvants to bleeding. Opium in cases of inflammation is oftener an excitant than a calmant; in the normal state it causes congestion of the hemispheres; and one must be bold enough to employ it in high doses, in order to render the congestion comatose. It is, however, more prudent to employ with energy and celerity the rational means which the disease indicates, viz., bleedings and revulsives.

An Italian physician is said to have cured two cases by employing morphine by the endermic method. Purging is always of use, although its effect is only secondary; to excite the skin, warm or vapour baths, followed by dry friction, have been much employed, as well as many other means which we must consider as empirical. In this category we range mercury pushed to salivation; phosphorus, which is a dangerous stimulant of the brain and spinal marrow; the subcarbonate of iron, arsenic, and the oil of turpentine.

Chorea.—The methods of treating chorea are also very numerous, and, although differing from each other, are all in favour on the score of cures. We have, therefore, to pass in review those most in repute, bearing in mind that this disease consists especially in a partial inflammatory irritation of some fibres or fasciculi of the nerves belonging to the contractile motility.

The practitioners who, on the authority of Sydenham, believed that this disease was produced by the humours, whose evil influence irritated the nerves, administered purgatives largely, conjointly with blood-letting; this empirical method was often successful from its derivative power, but their manner of explaining it was absurd. Cullen thought that bleeding ought to be reserved for plethoric patients, and forbade the use of purgatives when the general state was asthenic. In this state he recommended bark and iron; his successes must have been few from such treatment. Bouteille's treatment was more appropriate: two or three bleedings, of from three to six ounces each. M. Serres recommends, in recent chorea, the application of leeches to the upper part of the cervical region and round the occiput. M. Guersent, on the contrary, formally forbids blood-letting, which he thinks is seldom indicated in this disease, and he has always found it injurious; but he speaks of such cases in young children only, which may differ greatly, not only in indications but results, in adult persons. Dr. Peltz, who considers chorea to be an inflammation of the arachnoid, proposes in the acute form reiterated applications of leeches to the temples, purgatives, and the mustard pediluvium; and in the chronic form, tincture of iodine, of which he speaks favourably. Others, after leeching, make use of blisters, and cautery along the spine.

M. Chrétien relates five or six cases successfully treated by repeated frictions with Rosen's liniment, composed of two ounces of gin, half a drachm of oil of cloves, and of balsam of muscade: an innocent method which smack strongly of the middle ages. I can more readily understand the favourable action of the ointment of tartarized antimony employed in frictions on the scalp, or along the spine, when it produces a revulsive eruption. Breschet's plan is also based on derivation; he administers tartrate of antimony in the dose of four, six, or eight grains, but in combination with opium, and in some strong aromatic infusion, to prevent vomiting: he gives, at the same time, pills composed of aloes, scammony, and jalap. The pills being of three grains, he begins with one, increasing the number successively, and giving them every three hours. Dr. Elliotson states that he has been successful in a large number of recent cases of chorea, in young and robust subjects, with the subcarbonate of iron. M. Baudelocque makes a similar statement: he also employed sulphurous baths, and cured almost all his patients by keeping them in the bath for an hour each day. Dupuytren had a high opinion of cold bathing, and thought it efficacious in all cases of chorea; he used to order them in the form of douche, *par surprise*, in affusion, or in the river or sea, aiding their effect by swimming and all bodily and gymnastic exercises. We think this plan liable to very serious objections, and that it should only be recommended in extreme cases, and after all other means have failed.

Convulsions.—The treatment of convulsions is sufficiently indicated by the very nature of the disease, and on this point the curative method recommended by all practitioners is almost the same. The first thing is to combat the cerebral plethora by repeated applications of leeches to the neck, temples, and mastoid processes. In the case of cerebral or meningeal inflammation, we must, besides, have recourse to general blood-letting. If the convulsions arise from teething, some leeches may be applied to the gums, although this is not so easily done on children. In cases of general exhaustion, or anemia, sanguineous evacuations are altogether improper, in lieu of them we may employ energetic derivation on the skin of the limbs; we should not be afraid to envelop the two legs in mustard poultices, taking care to limit the duration of their application. In those cases of anemia where the patient complains of severe pain, good effects are obtained from the use of narcotics and stimulants, such as spirit of ammonia, preparations of ether, tincture of castoreum, &c.

After the brain has been unloaded, the oxide of zinc, combined with henbane, has been employed with success; some practitioners have recommended sulphate of quinine. Mild purgatives should be employed to aid the treatment, by keeping the bowels free; and for this purpose purgative enemata, alternating with those of assafœtida, produce good results. If any eruption had disappeared, an attempt should be made to renew it by the warm bath, or very hot fomentations.

ORIGINAL CONTRIBUTIONS.

PRACTICAL REMARKS ON THE EMPLOYMENT OF IODINE, AND ON THE COMPARATIVE VALUE OF THE LOCAL AND GENERAL TREATMENT BY IODURETTED PREPARATIONS.

By Dr. LUGOL.

Translated for the Medical Times by ALFRED MARKWICK, Esq., Surgeon to the Western German Dispensary, and formerly Externe to the Venereal Hospital, Paris &c.

In St. Prosper Ward there is a child aged eight years, named Felix Domergue, who came in on the 28th of Nov., 1845, presenting the signs of a tubercular diathesis, which he had manifestly inherited from his parents.

This little boy has on his left thigh a chronic abscess which commenced about two months ago, and now forms on the anterior, internal, and inferior part of the limb, a soft fluctuating tumour, half the size of the head of a fœtus at full term, and having on its front part a spot where the skin is red and thin. The abscess, however, does not extend beyond the condyles of the femur, neither does it communicate with the knee-joint, and, consequently, the patient can walk without any very great degree of difficulty.

There is a fistula on the right foot, corresponding to the fifth metatarsal bone, which is kept open by caries of this bone, and first began about three months since.

The general state of the patient is satisfactory, with the exception of a slight cough; his strength and *embonpoint* have not much diminished, and his appetite is good.

On December 1, an incision about an inch in length was made in the external and most dependent part of the tumour, when more than a quart of reddish pus, containing fibrinous clots, escaped. A weak solution of iodine was then injected into the cavity, and a simple but slightly compressive dressing afterwards applied, a pledget of charpie having been previously inserted between the lips of the wound.

The injection was repeated on the following days, at the end of which time the swelling of the surrounding parts, and the purulent discharge, began to decrease, and in about three weeks the wound resulting from the artificial opening of the abscess was cicatrized; this opening did not, however, prevent the ulceration of the skin in that situation, where, as I have mentioned, it was red and thin, and therefore the pus escaped also through this aperture, which has remained fistulous.

Eight days after the abscess was opened, the little patient got up and walked about without a crutch, by using the affected limb.

But little matter now escapes through the fistula of the thigh, which is kept open by disease (probably necrosis) of the lower half of the femur, to which the abscess is owing.

The patient can now walk with scarcely any limping, and his health is very good. No alteration, however, has taken place in the fistulous caries fifth metatarsal bone.

Victor Marting, shoemaker, aged 23, came in on the 19th of December, 1845. On the right side of his neck there is a tumour, rather larger than the fist, extending from the lobulus of the ear to within two fingers' breadth of the clavicle, and oc-

cupying from before backwards the space of four fingers. It commenced in the month of May, being at that time about the size of a hazel-nut, and in three weeks had increased to that of a walnut. It then remained stationary until the month of November, when it began gradually to enlarge to its present size. At this period the patient felt a little pain in it of a lancinating kind, but it was never very acute.

On the 22nd of December the tumour, in which there was fluctuation, was punctured, and half a pint of very fetid pus made its escape. Three consecutive iodine injections. Repetition of the injections once daily up to the present time.

The tumour was reduced to less than half its original size by the puncture; it has since diminished, and is, moreover, much less hard; but it still has the tubercular character, and there is an abundant discharge of purulent matter at each dressing. The patient has not yet recovered his appetite or his strength; neither has he, he says, regained all his energy, although his general state of health is at present tolerably good.

Charlut, gendarme of the Seine, aged 41, had a tubercular tumour, larger than the fist, on the right lateral region of the neck. It commenced by a tubercle of the size of a hazel-nut, which remained nearly stationary for fifteen years. In the corresponding groove there was a tubercle of about the same size, which appeared at the same time as that on the neck, but did not get any larger.

For the last twelvemonth, but more particularly since last autumn, and still more so during the last fifteen days, the tumour has increased to such an extent as to prevent the patient from wearing his regimental stock, and from buttoning his coat, although it has been almost free from pain. Charlut on this account obtained leave of absence in order to get into St. Louis Hospital, where he was admitted on the 5th of February, 1846. On entering he was ordered an alkaline bath, and a purgative to be repeated on the third day. After this preparatory treatment the tumour was punctured on the 11th of February. More than a pint of tubercular pus, having a nauseous odour, was discharged, which towards the end was mixed with a good deal of blood.

Immediately after the puncture a solution of iodine was injected into the cyst, and repeated three successive times, the injection each time bringing away with it pus mixed with blood. When the operation was completed the patient was placed in an alkaline * bath, and while there, about a glass full of pus mixed with a large quantity of blood escaped through the incision. The iodine injections were continued on the following days. On the fourth day the patient had slight shiverings, frequent horripilations, headache, thirst, and no appetite. He was therefore purged a third time, not with seidlitz water, as on the two former occasions, but with calomel and jalap: whereupon the fever disappeared, and the appetite returned.

On the 22nd of February, the eleventh day after the operation, the tumour was reduced two-thirds in size, but there was still a discharge of pus at each dressing. The patient, however, at his own request, left the hospital, believing himself to be in a fit state to go on duty, but was recommended to continue the iodine injections. Although he has followed this advice, the tumour is now (fifty-two days after the operation) in the same state as on the eleventh; and, as he has not been able to wear his uniform to go on horseback, he has only taken to a sedentary duty in the barracks.

The patient says he no longer experiences the uneasiness to which he was subject previous to the operation, but I may mention that he has had a cough ever since he left the hospital; that a sister, aged 26, and a brother, aged 21, have died of pulmonary phthisis; that he lost eight other brothers and sisters when very young; and that he has now but one sister, the mother of two tubercular children, left. These antecedents and coincidences sufficiently explain the continuance of the tubercular discharge from the neck, and ought to direct our attention to the cough which has commenced since this subcutaneous tubercular suppuration was excited.

I have not alluded to the internal treatment that was commenced in the hospital, because it was of too short a duration, not having been continued after the patient quitted St. Louis. The plan of injecting a solution of iodine into a tubercular abscess, after it has been punctured, I have had recourse to in my hospital and private practice during the last fifteen years, in cases similar to those just referred to. Whenever I ascertain the presence of tubercular matter in the soft parts, I effect its discharge by means of a puncture; and after the evacuation of the cyst, I inject into its cavity a solution of iodine; this injection serves both to more completely empty the cyst of the pus which it may still contain in some of its sinuosities, and also to bring the iodine in contact with its internal surface, in order to modify it in a particular manner, and produce in it the adhesive inflammation.

During the two first years of my researches on the therapeutic effects of iodine in scrofulous patients (1827 and 1828), I made use of an iodine solution for the local baths of which we have just spoken,* and at this same period administered iodine water † internally, for I had not then discovered the formula for the iodurretted water.

After having given a formula for an iodine water to be administered internally, and an iodine solution for external use, I continued my investigations in order to find another for iodine baths; and I attached the more importance to the obtaining this new mode of administration, as it appeared to me, *à priori*, capable of very advantageously assisting to multiply the good effects of the treatment I had successfully pursued since that time. The results I obtained were beyond my most sanguine expectations; for, although I did not succeed in finding a satisfactory formula for iodine baths, I had the good luck to discover something still better, namely, one for iodurretted baths, by means of which I have since perfected the greater number of those I had previously employed. Consequently my memoir on the iodurretted baths may be considered as the foundation upon which I have hereby based my method of treating scrofulous diseases.

In the first place, in order to arrive at the formula for iodine baths, I performed three experiments; but at the third it was evident they could not be formed, and that, therefore, to be able to find out what I wanted, I must adopt some other proceeding.

For the better understanding what I am about to say, I will allude in a summary manner to this third experiment.‡

Three drachms of very pure iodine were dissolved in six ounces of rectified alcohol, and the spirituous tincture thus formed afterwards added to a hot bath at 50 deg. Reaumur. As this alcoholic solution was being poured into the bath, violet-coloured vapours were seen to rise from the surface of the water, and in a few moments the atmosphere was so loaded with them that those who stood by became inconvenienced by the irritation they produced in the eyes, the nasal fossæ, the pharynx, &c. Before this experiment was ended, the odour of the iodine had passed through the walls of the bath-room, and had reached as far as the courts of the hospital, even before the baths could be emptied. Moreover, the iodine was seen to deposit itself in the solid form on the sides of the bath; consequently the alcohol, weakened by the water, had abandoned the iodine, which, being thus isolated, became disengaged partly in the form of violet-coloured vapours, and partly as molecules suspended in the water.

The same phenomena occurred seven times in the same space of time, inasmuch as I operated on seven scrofulous patients, in order to act on the principal forms of the disease. The sight of them made me reflect on the internal administration of the alcoholated tincture of iodine, and they fully confirmed the remarks I had already made on this preparation of Dr. Corridel's, the use of which I have always objected to for the reasons I have given at page 46 of my first memoir. It is evident, from what then took place before us, that the internal use of this tincture must be followed by a deposit of the iodine in the solid state on the coats of the stomach—a circumstance that cannot fail to be injurious to the patient, in consequence of the very strong affinity of this body, when in an isolated form, for animal substances, which it decomposes with great activity.

Having failed in my attempts to find the iodine bath—the iodated bath, properly so called—I endeavoured to discover by some other means the solution of the problem to be resolved. For this purpose I commenced a second series of experiments.* This led me to the composition of the iodurretted baths—that is to say, to the preparatory solution of the iodine, not in alcohol, but in iodide of potassium, which is an excellent solvent for it, and which contains a very large proportion of it in the state of a neutral salt. This solution is obtained by combining one part of iodine with two of iodide of potassium. These proportions of the two bodies produce a mixture which is equal in all its parts, and which is perfectly soluble in distilled water.

Such is a summary description of my labours to arrive at the formula for iodurretted baths, and which have caused me to entirely abandon the use of iodated solutions, and to prescribe nothing but iodurretted ones, both for internal and external use.

For the last fifteen years,—that is to say, since I discovered the formula for the iodurretted baths—I have not employed any iodated preparation. My practice relative to the administration of the iodurretted preparations has acquired every possible notoriety, since it is described in my works, and has been propagated in Germany, England, and the United States, by the numerous translations of them that have been published, and by the favourable reception they have met with from the medical press of all countries. I have also endeavoured to make my method still more known by the special clinical instruction I have created at the Hospital St. Louis: I say created, because I have never entertained those who attended with anything but my own researches.

From these antecedents, and others which I will not mention, I shall, I think, be authorised in expressing my opinion on the more recent employment, by certain practitioners, of an iodated solution in cases of hydrocele, and also for the cure of chronic abcesses. Far from being an improvement, I consider that to return to these preparations which I have long since abandoned, and to speak of iodine injections and collyriums, &c., as was the case at the time of my first labours, is to make a retrograde step in the art of prescribing. We thus go back to the period when my first memoir on the employment of iodine in scrofulous diseases was published, and when I had as yet given no other formula than for iodine solutions for internal and external administration. With respect to this latter mode of administering iodine, there has been some degree of surprise, which those who eagerly seek for truth will soon overcome.

* We are no longer able to give iodine baths to the patients at the St. Louis Hospital, in consequence of the very high price of the iodine, occasioned by the enormous abuse that has been made of it, during the last few years, contrary to the rules I have laid down respecting its employment.

* Memoir on the Employment of Iodine in Scrofulous Diseases, read at the Academy of Sciences on the 28th of June, 1829; preceded by the Report made to the Academy by MM. Magendie, Serres, and Duméril, reporters.—Paris, 1829; page 54.

* Memoir on the Iodurretted Baths, pp. 34 *et seq.*

Several cases of poisoning among children have occurred during the last fortnight in the eastern parts of London, by the fruit of the atropa belladonna being sold for wortle-berries. Inquests have been held in the London Hospital on several occasions, and the person who sold the berries, having, in the opinion of the jury, shown culpable negligence, has been fully committed to take his trial for manslaughter.

ON THE PROPRIETY OF EARLY OPERATIONS IN CASES OF STRANGULATED HERNIA.

By GEO. SAYLE, M.R.C.S.,
King's Lynn, Norfolk, formerly Curator of the Anatomical Museum in the St. George's Hospital School.

The following remarks, although drawn up for a different purpose, may not be altogether uninteresting. They consist of three heads:—1st, The opinions of many authors who have written upon the subject, from the earliest times to the present. 2nd, My own opinion derived from observation of cases operated upon. And 3rd, A tabular form of thirty-six cases, collected indiscriminately from the works of different authors and various periodicals. A comparison of the whole will show how far experience agrees with what is recorded in books.

It is pretty evident the ancients knew little of the pathology of the disease, nor did the moderns much improve upon their practice until the last few years.

Celsus, Galen, Œtius, Albucasis, Avicenna, and a host of others of an early date, evidently performed an operation *not* for strangulated hernia, but as a radical cure for "rupture"; nay, more—they held it to be bad practice to perform the operation whenever pain, vomiting, &c., were present. "Rursus, si ætas processit, multumque intestin descendisse ex tumore magno patet, adjiciunturqu dolor et vomitus; quæ ex stercore, ex cruditate e delapso, fere accidunt; scalpellum adhiberi sin perniclo non posse, manifestum est; lerandum tar tummodo malum, et per alias curationes extra hendum est."*

Until the last century, surgeons were divided i opinion as to the propriety of operating when evi dent symptoms of sphacelus or mortification were present. "These ruptures are often attended wit danger, especially the incarcerated, in which, i the intestine be not timely returned, but the stric ture continues two or three days, red and livid spot appear upon the tumour, which denote a sphacelu or mortification, and, if a universal cold swea seizes the patient, he has generally but a few hour to live. In this case many prudent surgeon omi the operation as useless, to avoid reflections, a being instrumental to the patient's decease."†

The same author also advises the following remedies,—Bleeding, cataplasms, ointments, laxatives, and tobacco clysters, which having failed he adds, "When the surgeon perceives that it i impossible to return the intestine, and finds by the great inflammation, pain, and vomiting, that th disorder will be fatal, he should acquaint th patient and his friends with the *great necessity* there is for him to undergo the operation, to preven a mortification and subsequent death."

It is evident from the above that Heister and hi contemporaries were in favour of operating as soon as other means had failed, and these were not to occupy *more* than forty-eight hours.

An author about twenty years later, after mentioning two or three cases of artificial anus produced naturally, and by such means the disease being cured, writes,—"These cases, however, are only mentioned to furnish surgeons with the knowledge of the possibility of such events, and not to mislead them so far as to make favourable inferences with regard to gangrenes of the bowels, which generally are mortal."‡

His preliminary treatment consisted in bleeding, injections, fomentations, and then the taxis, after which, the hernia being still unreduced, he recommends, after Peter Lowe, puncturing the intestine in five or six places, with a needle. Should this prove ineffectual, he adds, "After all, should the pain and tenseness of the part continue, and hiccough and vomitings of the excrements succeed, the operation must take place; for *if you wait* till a languid pulse, cold sweat, subsiding of the tumour, and emphysematous feel come on, it will be most likely too late, as they are pretty sure symptoms of a mortification."§

* Celsus, lib. vii., sec. xx.
† Heister, vol. ii., p. 47; 1743.
‡ Sharp's Observs., edit. vii.
§ Sharp Loc. Cit., p. xx.

We come now to a period when surgery far superseded that of the preceding generation,—to a time when practice was founded on more correct anatomical and physiological principles, which can be the only safeguard to an operating surgeon.

Benjamin Bell, in treating of strangulated hernia, recommends the taxis, bloodletting, an injection of tobacco smoke, cold to the part, opiates, and the warm bath. He objects to purgatives; "but," he says, "it frequently happens, notwithstanding every endeavour, that the protruded parts cannot be returned. * * * In this situation, when no probability remains of success from the employment of the means already mentioned, the division of the parts producing the stricture is then our only resource. This operation," he continues, "is, no doubt, attended with some hazard; yet, so far as from experience I am able to judge, the risk attending the disorder itself, when the operation *is long delayed*, is infinitely greater than is commonly experienced from the effects of the operation considered abstractedly." He concludes by saying—"It ought, therefore, to be laid down as an established maxim, always to proceed to the operation, if in the space of a *very few hours* bloodletting and the other remedies pointed out do not prove effectual. Two or three hours at farthest, even when the assistance of practitioners is early applied for, is perhaps the greatest length of time that should ever be consumed in trials of this nature."*

The preliminary treatment laid down by Mr. Bell continues nearly unaltered to the present time; I shall, therefore, mention only the opinion of his successors as to the propriety of early operations.

The late Mr. Hey, of Leeds, to whom our profession owes much, writes, "When I first entered upon the profession of surgery, in the year 1759, the operation for the strangulated hernia had not been performed by any of the surgeons in Leeds. My seniors in the profession were very kind in affording me their assistance, or calling me into consultation when such cases occurred; but we considered the operation as the last resource, and as improper until the danger appeared imminent. By this dilatory mode of practice I lost three patients in five upon whom the operation was performed. Having more experience, I made it my custom, when called to a patient who had laboured two or three days under the disease, to wait only about two hours. * * * In this mode of practice I lost about two patients in nine upon whom I operated. I have now, at the time of writing this (1809), performed the operation forty times, and have often had occasion to lament that I had performed it too late, but never that I had performed it too soon."†

The late Sir Astley Cooper, perhaps the most celebrated author who has written upon the subject, computes that the time occupied in treatment previous to the operation ought not to extend over four hours.‡

Mr. Lawrence, also an excellent authority, writes, "When, as it very frequently happens, the aid of the surgeon is not required until the complaint has lasted for some time, a trial of the tobacco, together with the topical use of cold, should be immediately resorted to, as circumstances *will not admit of delay* in the previous use of less powerful remedies."§

Mr. Guthrie remarks,—"That a hernia of recent formation cannot remain in a state of incarceration ending in strangulation, *for a longer period than ten hours*, without placing the patient's life in great jeopardy."‖

Mr. Samuel Cooper says—"In the treatment of strangulated hernia, a surgeon cannot be too deeply impressed with the danger of spending time in the trial of methods of inferior efficacy, or of such as are evinced to be ineffectual in the cases before them."¶

Sir Benjamin Brodie, although his opinion is not expressed, that I am aware of, in any of the standard works, writes, in answer to a letter requesting it:—"When I was a student at St. George's Hospital, the custom was (in a case of strangulated hernia) to defer the operation until a great number of other means had been employed, and had failed to accomplish the reduction. Under this treatment very few patients (usually not more than one in three or four) recovered.

"It is now a great many years since I adopted the plan of operating at an early period after the commencement of the strangulation; and, under this mode of treatment, I may venture to say that the failures have been even less frequent than the recoveries were formerly. You will observe, however, that the operation in hospital practice is never so successful as it is in private practice, and for this reason, that a patient in private practice generally seeks assistance *immediately* on the hernia being discovered."

§ Loc. Cit., 3rd edition. ‖ Guthrie on Hernia.
¶ Cooper's Dictionary.

From Professor Roux the report of a number of cases was received in addition to his opinion thereon, all proving the positive necessity of early resorting to the operation. In short, with the exception (I believe) of the late Dr. Heberden, that opinion has been invariably expressed in the strongest terms by all modern authors. I am satisfied, that although the taxis and other means may be employed almost with impunity, and occasionally with success, in cases strangulated only a few hours, the application of the taxis, in cases of three or four days' duration, tends very materially to destroy the success which might be looked for from the operation even at that late period. I feel equally satisfied that the shorter the period between the commencement of the attack and the operation, the greater is the chance of success. I will go further and say, whoever neglects to act on this principle must hold himself accountable for the fatal termination which usually follows delay; and, should some days have elapsed, I am confident the greatest (*in fact the only*) chance of success is in the *immediate* performance of the operation, and in not losing such precious moments in *useless proceedings*.

TABLE I.

Strangulation limited to twenty-four hours.

—*	Died.	Cotton.

* his [illegible] mained in the hospital forty-eight hours before the operation was performed, which she survived about two more.

The deaths are from the above tables in proportion to recoveries in the following proportions:—

In Table I they are 0 to 9.
In Table II. they are 1 to 5.
In Table III. they are 1 to 4.
In Table IV. they are 1 to 2 3-5ths.

OBSERVATIONS ON CHOLERA.

By DAVID M'CONNELL REED, Lic. Med., &c.

In the "Archiv. fur Physiol. und Pathol. Chemie und Mickroscopie," vol. ii., there appears an article on the "Analysis of the Urine, Blood, Fæces, and vomited matters, in Cholera Sporadica," by Dr. Heller.

From the experiments of Dr. Heller, it appears that the urine in sporadic cholera had a strong acid reaction, and was of specific gravity 1,018. The addition of nitric acid detected a large quantity of a peculiar animal matter, to which the deep colour of the urine (which is reported to be small in quantity, of a deep golden yellow colour, and possessed of a faint but very peculiar odour) was obviously due. When voided it was tolerably clear, but shortly deposited a small quantity of flocculent mucus, and a fine sediment of earthy phosphates. When first the acid was dropped in, an intense violet-red colour was produced; this, on shaking, was changed into a dark carmine red, and then to a dark violet, which remained. When a large quantity of acid was added, the colour assumed was a dark brown, which was permanent. These peculiar changes in colour produced by nitric acid were probably due to the presence of altered bile-pigment in the urine. Had the pigment been ordinary biliphœin, it is stated that a green instead of a red colour would at once have been struck on the addition of the acid. Another effect produced by the addition of nitric acid was the evolution of a large quantity of gaseous carbonic acid. No albumen was detected. The addition of ammonia caused an almost entire disappearance of the earthy phosphates, and changed the golden yellow colour of the fluid to a brownish red. The addition of a salt of silver to the acidulated urine showed that *almost all the chlorides had disappeared*. When the same salt was added to the non-acidulated urine, a precipitate was formed, which was soluble in nitric acid with an abundant evolution of carbonic acid gas. A salt of baryta detected very little of the sulphates, but also gave rise to an abundant evolution of carbonic acid. On boiling, all the carbonic acid disappeared; *which proved that the acid existed free in the urine*; and that it was in all probability *the chief cause of its high acidity*. One thousand parts of the urine contained 955·67 parts of water, and 44·33 parts of solid constituents, of the latter 10·50 consisted of urea (12·8 being the average quantity in health), about 0·10 of uric acid; 27·32 of extractive matters; together with a large quantity of the peculiar animal substance above described, and which, most probably, originated from bile; 6·41 of fixed salts, which consisted in great part of phosphate of soda and sulphate of potash. With regard to the uric acid, it should be remarked that the crystals of it thrown down by the addition of hydrochloric acid had a square form, and were of a beautiful deep blue colour. When viewed by reflected light, these crystals presented a brilliant violet-red colour, with a metallic lustre like that of titanium; by transmitted light, they appeared of a beautiful blue colour throughout, and formed a fine layer over the violet-coloured urine. The peculiarity of the uric acid crystals obviously resulted from their being combined with the pigment above described: for in addition to the previously-mentioned reasons for regarding this pigment as somewhat different from ordinary biliphœin, and as probably a modification of it, it may be stated that the crystals of uric acid, deposited through the action of hydrochloric (muriatic) acid, from urine containing even a very large quantity of biliphœin, as in the case of intense jaundice, are never blue, but always yellow. *The almost complete absence of chlorides (muriates) from the urine is also very remarkable, since these, especially chloride of sodium, appear to fulfil an important part in the system. Lastly, the large quantity of free carbonic acid contained in the urine is a highly curious circumstance*, but it is often found largely in the urine, in combination with ammonia, but it is then a product of the *decomposition of urea*, and is coincident with an alkaline condition of the urine. But in this case there was *no carbonate of ammonia present*, and the urine possessed a *highly acid reaction*. The foregoing observations on the urine in sporadic cholera are attributed to Dr. Heller.

Now, let me observe that an atom of urea, an abundant ingredient of healthy urine, is composed, according to Drs. Prout and Berard, of two atoms of hydrogen, one of carbon, one of oxygen, and one of nitrogen, and may, therefore, be considered to be a kind of carbonate of ammonia with excess of hydrogen. It is reported to manifest neither an acid nor alkaline reaction, nor is it found to undergo any change from the atmosphere, except a slight deliquescence in very damp weather. But it forms, with nitric acid, the acidulous nitrate of urea, evidently manifesting, in this relation, alkaline properties. It would therefore seem that it is indebted for its neutral properties to the excess of hydrogen which it contains; and that the operation of nitric acid in combining with it, is first to convert the excess of hydrogen which it contains into water by affording oxygen to it, and then forming with the alkaline substance which results an acidulous salt. Perhaps the only difference between urea and uric acid is, that one contains excess of hydrogen, the other excess of carbon, in relation to the other ingredients; and that the one has neither acid nor alkaline reaction, whereas the other has a decided acid reaction. Be this as it may, they are usually found to prevail in the urine under different diatheses; an excess of urea generally accompanies what is called the phosphoric diathesis, or that in which the earthy phosphates abound in the urine; whereas, the lithic diathesis seems to be that state in which pure lithic acid abounds in it.

In sporadic cholera, however, according to Dr. Heller, the urine appears to be deficient in urea; whence I argue that there is a deficiency of oxygen, hydrogen, and nitrogen, in relation to carbon, in the blood; and that the deficiency of these elements is owing to deficient consumption or decomposition of pure air, water, and chloride of sodium by the system. Dr. Heller considers the absence from the urine of the chlorides (I suppose he means the muriates) to be very remarkable, since the former (in which I agree with him), especially the chloride of sodium, appear to fulfil an important part in the system. (See my work on Fever Physiologically Considered, &c., lately published.)

Dr. Heller noticed that the urine in the above case possessed a strong acid reaction, which he considered to be owing to the presence of free carbonic acid in it.

Although this may at first sight appear to be at variance with my opinion, that cholera essentially depends on a deficiency of oxygen in the blood, yet I think that on close examination it will be found to be confirmatory of it. For, let it be remembered that unoxygenized blood—the liquor sanguinis—consists of a great variety of inflammable substances, with metals and earths in a minute state of division, in the form of globules suspended in a solution of animal matter, and chloride of sodium in water. This is the state of the fluids before they undergo that change whereby they become blood. Now, these inflammable, metallic, and earthy substances require to be oxygenized in order to be able to sustain life—the action of the system; but, to be efficacious to this end, this process must take place in such a manner as to leave the blood, after it has made its circuit—that is, the venous blood—in a perfectly neutral or saline state. In order to this, however, the liquor sanguinis must meet with such a supply of oxygen, whether in the lungs or in the course of circulation, as will effectually convert all its inflammable constituents into acids, and its metallic and earthy bases into oxides, in such a proportion as to neutralize each other, and to form perfectly neutral secretions and excretions. These are the conditions of health, nay, even of life; and in the constant recurrence of these changes in its constituent corpuscles consists the vital action or *life of the blood*.

It will hence appear that either an acid or an alkaline state of the blood (both inconsistent with its healthy function) may arise from a partial supply of oxygen—in other words, a deficiency of oxygen—in the system; whence only some of the inflammable substances are converted into acids, or some of the metals and earths are converted into oxides or alkalis, and the remainder of them are left unchanged.

In the foregoing case we have reason to suspect a deficiency of ammonia in the blood during life; for, as was already hinted, urea may be considered to be a compound of carbonic acid and ammonia with excess of hydrogen; but here we have a deficiency of urea, and a redundancy of carbonic acid; whence we conclude that, if there had been more ammonia and hydrogen in the blood, there would have been less carbonic acid and more urea in the urine.

Now, it has been shown that there was almost a total absence of chlorides (muriates) from the urine in the above case; whence we conclude that they (the muriates) could not have been present in the blood: for the nature of the urine is a sure index of the nature of the blood. The operation, however, of the chlorides in the system, is to decompose water, so as to supply oxygen to the inflammable substances, and metals and earths in the liquor sanguinis; to conduce to the formation of ammonia, and the decomposition of atmospheric air. (See my work already alluded to.)

In the foregoing case there was also noticed great deficiency of the sulphates in the urine, which also argues a deficiency of oxygen in the blood.

On the whole, then, we conclude that carbonic acid was formed to the detriment of the neutrality of the blood; and that it was the result of a deficiency, in the system, of the acidifying, oxidifying, and alkalifying principles—in other words, a deficient consumption or decomposition of the substances which yield them, viz., pure air, water, and common salt.

The blood which served for analysis was obtained from the carotid artery *after death*; and, therefore, no certain conclusions can be arrived at respecting its state *before death*. It was, however, reported to be generally fluid, though coagula were found here and there in the bloodvessels, and especially in the cavities of the heart; it was very dark, yet strongly coloured, and of a tolerably thick consistence. The quantity of fibrine was very small. Beneath the microscope, the blood corpuscles appeared indented, and many fat globules were observed. The serum, after the subsidence of the red corpuscles, was of a dark yellow colour, and an alkaline reaction. It contained a full quantity of albumen, but not a trace of biliphœin could be detected. The quantity of fat was large; that obtained by ether and alcohol was perfectly saponafiable, and contained no cholesterine. When examined for urea by Simon's process, it was found to contain a very large quantity of this substance. This was manifestly the result of the great suppression of urine. The proportion of fixed salts in

the blood was much increased, especially the chlorides of sodium and of potassium, the muriates which were absent in so marked a degree from the urine. A similar circumstance was noticed by Phœbus.

From the whole account of the blood taken together (although, as before said, it was extracted from the patient after death, and therefore not likely to present a correct specimen of the blood during life), I conclude that it was deficient in oxygen.

This is proved by the deficiency of fibrine, the dark colour, the fluid state, the quantity of fat present, the presence of much urea and chloride of sodium and potassium, and the absence of muriate of ammonia and muriate of soda and potassa.

The fæcal evacuations, which were very abundant and frequent, were watery and of a turbid, whitish, gruel-like appearance; the fæcal odour was but seldom perceived. They had an alkaline reaction and contained albumen. By nitric acid their colour was changed to a deep brownish red, which passed into violet, exactly resembling, therefore, the changes produced in the urine by the same re-agent. ammonia also produced here the same dark-brown red colour as it did in the urine. The same peculiar substance, therefore, which was found in the urine and regarded as altered bile-pigment, was present also in the fæcal evacuations. Simon also, as well as others, mentions the peculiarity of the bile in the fæces of cholera becoming frequently red instead of green, by nitric acid. Crystals of ammonia and phosphate of magnesia were also found in the fæcal evacuations in this case.

It is difficult to know to what to attribute the want of colour in the fæces, and the changes produced upon them by nitric acid, unless we suppose a total deficiency of oxygen, chlorine, and hydrogen in some of the constituents of the bile—perhaps the picromel. We know, however, that to the presence of picromel is owing the peculiar greenish-yellow colour of the bile. We also know that substances capable of supplying oxygen, hydrogen, and chlorine, to the blood, are efficacious in restoring the bilous colour to the stools, when lost. Upon the whole, then, I lean to this opinion in the absence of a better explanation of the difficulty.

The matters vomited during the progress of the disease are very watery, and of a greenish or yellowish green colour, and a slight acid or neutral reaction.

Bile was the most essential ingredient, and it reacted towards nitric acid as ordinary biliphœin would, the first change in colour produced by the acid being green. The peculiarity of the matter vomited probably consisted in its containing bile with an excess of carbonic acid; which accounts for its acid reaction, for pure bile would have been rather of an alkaline reaction, from the presence of free soda in it. But the deficiency of this substance in the bile, notwithstanding the presence of carbonic acid, when compared with the quantity of chlorides of sodium and potassium which the blood was reported to contain, may be considered as an evidence that there had been a deficiency of free oxygen and chlorine in the system.

The article terminates with the following observation :—"In conclusion, it would seem as if in this disease a peculiar change or decomposition was undergone by the bile, and it would be important to ascertain whether a similar alteration of this fluid takes place in other cases." The same observation may, with equal propriety, be applied to the urine and the perspirable matter; and, perhaps, it would be more correct to apply it to the blood, on the state of which depends the quality of all the secretions.

In confirmation of the opinions here advanced, respecting the nature of cholera, I shall extract some observations from an article on cholera, made by Mr. Ffrench, surgeon to St. James's Infirmary, which appeared in a late number of the "Medical Gazette." This gentleman finds fault with Dr. Copland's view of the nature of cholera, and considers it to consist essentially in paralysis of the lungs, and proposes to name it pestilential asphyxia. Mr. Ffrench's objection rests on the supposition that the action of the heart and brain cannot cease without a previous suspension of the action of the lungs. Now, this supposition is not correct; for in syncope the action of the heart and brain ceases before the action of the lungs; and in asphyxia (an objectionable term, because it signifies want of pulsation) the action of the lungs ceases before that of the heart and brain. But, although I cannot agree with Mr. Ffrench as to the grounds of his objection, yet I am not prepared to dissent from him wholly, in the view which he takes of the subject, since he considers cholera to consist essentially in paralysis of the heart. Mr. Ffrench, however, having led us so far, leaves us in the lurch; nor does he afford us the slightest clue in discovering the cause of the said paralysis of the heart. He compares cholera to "dropped hand," and tells us that the quickest mode of curing it is to place it upon a splint, and in a sling, and at the end of three weeks the power of the limb is found to be regained; from which I suppose he would infer, that the quickest way of curing cholera is to let it alone. Mr. Ffrench, however, very properly objects to the use of diffusible stimuli in the treatment of this disease.

Now, I think I have supplied the hiatus which appears in Mr. Ffrench's account of the nature and treatment of cholera, by attributing it to a loss of irritability in the contractile fibre, arising from a deficiency of oxygen in the system; and by showing that the proper treatment of the disease consists in the exhibition of such substances as are capable of communicating this principle to the blood. And this appears to be the true view of the subject, whether we consider the exciting, predisposing, or proximate causes, or the operation of those remedies which have been most efficacious in the cure of this disease.

A pamphlet has been lately published by Dr. Parkin, wherein the exhibition of carbonic acid is proposed as the *antidotal treatment* of cholera; but, as a large quantity of this substance appears to be generated in the system during the disease, it is probable that the effects attributed to carbonic acid by Dr. Parkin, are in reality due to the neutral compound which results from his prescription, the carbonic acid escaping before it reaches the stomach, or, at all events, being rejected by vomiting as soon as it reaches that viscus.

In conclusion, I shall quote an observation which occurs in Mr. Ffrench's paper :—"The treatment of cholera, indeed, however injudicious, will not prevent a considerable number of patients recovering from this disease; so much so that each practitioner, pursuing any mode of treatment whatever, will congratulate himself on his extraordinary success. So it was with the physicians of a former day in the treatment of smallpox by stimulants and close rooms." The treatment, however, which I have published, as likely to be most efficacious in cholera, has been put in practice in three instances, wherein members of my own family (one an infant of eight months old, another a bride, and the third an elderly lady) were severely attacked with this disease; and, I am happy to say, it was attended with the most marked success. In two other instances, however, wherein my advice was not followed, one of the patients (an infant) died; and the other had her complaint (which was at first trivial) so much aggravated in the lapse of three days, as to be reduced to the very verge of the grave.

Whatever, therefore, may be the fate of the opinions which I have published on this subject, I myself have the very best reasons to be persuaded of their correctness; and I should wish others who question them, or who have none of their own, to put them to the test of experience.

11, Queen's-road, Notting-hill,
August 27, 1846.

PERFORATION OF THE STOMACH.

By GEORGE HILL SMITH, Esq., Surgeon.

Mr C., a farmer, tall, thin, and healthy-looking, sent for me to see him on the 24th of April last; he was then suffering from an œdematous state of the legs, the result of erysipelas, which had attacked him a fortnight before. He complained also of symptoms of indigestion, and irregularity of the bowels. He stated that for some time he had felt uneasy after his meals; there was great flatulence, and frequently a pain in the epigastrium; his bowels were irregular, but his appetite very good, and he indulged it freely. These symptoms increased when the erysipelas appeared. At the time I saw him, however, he more particularly called my attention to the state of his legs.

Under the use of stomachics, alteratives, and local applications, his legs became somewhat better; but his dyspeptic symptoms continued, in consequence of which I remained in attendance upon him for several weeks.

On the 6th of June I was hastily summoned, and on arriving at his house, at two o'clock in the afternoon, I found him lying on the sofa, complaining of constant, excruciating pain in the epigastric region. His countenance was pale and expressive of great agony; his pulse was small, rapid, and thready. He had no vomiting. On inquiry, I learned that he had dined at one: had eaten a hearty dinner of pork and lettuce; that afterwards he suddenly felt a severe pain across the epigastrium, and was obliged to lie down and send for assistance. His bowels had been open before dinner.

Thinking that a fit of indigestion had probably come on, aggravated by the indigestible food he had taken, I ordered an emetic of ipecacuanha and antimony; it had not the least effect, however, and was repeated without avail.

The pain continuing very severe, calomel and opium were ordered, to be followed by a dose of castor oil; and after waiting some time the castor oil was repeated, but it had not the slightest effect. As his bowels continued so obstinate, and the symptoms increased in severity, two enemata were administered, without the least effect, and the calomel and opium were repeated every two hours. Hiccough appeared in a few hours, and during the night the symptoms increased. In the morning, as his bowels still remained so obstinate, I gave him two drops of croton oil, which, having no effect, were repeated without any benefit. During the day the symptoms increased in severity; the pain increased; the abdomen became tympanitic; the countenance was more anxious; the pulse became very rapid and thready; the extremities cold; and he died sensible at seven P.M., not having experienced the least alleviation of his sufferings.

Post-mortem Examination, eighteen hours afterwards.—On opening the abdomen, which was very much distended, a quantity of fluid appeared, amongst which I could distinguish the various medicines almost in an unchanged state; there was also some of the meal of the previous day. On carefully examining the stomach—which was collapsed at its lower border, about an inch from the pylorus—I found an ulcerated opening about the size of a shilling, through which I could easily pass my fore finger. The edges of the ulcer were regular and smooth; the mucous membrane around the opening was inflamed; the mucous membrane altogether was highly congested; the rest of the intestinal canal was healthy, as well as the other viscera.

Stevenage, Hertfordshire, Aug. 28.

How few medical men were candidates in the last election of the Chamber of Deputies! how few were elected! This is vexatious to our profession, which in this respect is deficient of the necessary renown and the essential support. The more numerous the medical electors, and, if possible, the deputies, the more our just and frequent protests will carry weight and have chances of success. There are, however, contrary prejudices; there are people who imagine that the Chamber of Deputies is not a proper place for physicians—that their part in it is too secondary. Such a prejudice seems to us to proceed from ignorance and folly. Public affairs are our affairs; to maintain the contrary is an absurdity. Why not take in the representation of our country a part more direct and positive? Not only a greater number of medical men are necessary in the Chamber of Deputies, but we doubt not that, if there, they would introduce into it those high views and conclusive reasonings which they necessarily gather from the profound study of their art.—*Gazette Medicale de Paris.*

Reported by WILLIAM ANDERSON, Esq., Student at St. George's Hospital.

MEDICAL CASES.

SUBJECT—HYSTERIA.

(Continued from p. 432.)

Of all the maladies to which the human frame is liable, there is probably none which is more distressing to the patients and their friends, and more annoying to medical men, than hysteria.

The disease is harmless as far as life is concerned, but the fits which accompany it, and the strange freaks and fancies which the patients have, are sources of the greatest alarm and anxiety to their friends, and of extreme perplexity to members of our profession, since the treatment is generally very unsatisfactory, and the cure often but imperfect.

The subjects of this complaint are almost always females, probably on account of their being more delicately constituted than men, their spirits being raised or depressed by much slighter causes,—in fact, to use a common expression, they are of a much more excitable temperament than the other sex. Now, with regard to the symptoms: the most striking of these is, probably, the hysterical fit; this for the most part commences with a wild expression of countenance, the eyes roll, the teeth are tightly clinched and ground together; the whole frame becomes convulsed, the patient struggles violently, tears her hair and clothes; the breathing is deep and difficult, and there is palpitation of the heart; the face is flushed and generally thrown back, with the throat projecting; this state soon passes off, and the patient lies quiet and exhausted for a short time, until the paroxysm suddenly returns and is again succeeded by a calm.

In this manner these paroxysms and periods of rest alternate with one another for a time, varying considerably in different cases, until the whole generally terminates in a violent fit of tears, sobs, and laughter. If this fit were the only symptom we had to deal with, the disease would be much more manageable than it is; unfortunately this is not the case: the symptoms are almost innumerable, aping almost every known disease, and often with such exactitude that men of the greatest skill have been misled by them; for instance, we may be summoned in a great hurry to a patient with all the symptoms of peritonitis, and it then of course becomes a matter of the utmost moment to decide whether it be really peritonitis or not, for in the one case the antiphlogistic treatment would only serve to aggravate the mischief, while in the other the want of timely depletion would probably cost the patient's life. In both cases our diagnosis should be quickly formed, in order that in the one case we may allay the fears of the patient and her friends, and in the other that our treatment may be prompt and decided. We have a good example of this in the case of Charlotte Atkins (case 1st); for on the 22d of May we find her with a rapid, weak pulse; red, glazed tongue, her legs drawn up, and complaining of violent pain in the abdomen, which is tympanitic, and which she cannot bear to be touched, even by the bedclothes. But here is one grand diagnostic mark between the two diseases, the hysterical and the true, viz., the effects of *touching*; she cannot bear to have her abdomen touched, but if her attention be drawn away she can bear not only pressure, but will even allow her bowels to be squeezed in the hand, without showing any sign of pain. Now, in a true case of peritonitis this would be impossible: however much we might attempt to draw off the attention, the same excruciating pain would continue, and that pain would be aggravated by even light pressure, and would be far too severe to allow anything like the pressure which is submitted to in the other case. There is another symptom here also worthy of notice, and that is the quality and quantity of the urine; it is pale, clear, and voided in considerable quantity; this is almost invariably the case in all forms of hysteria, but I have never heard of or seen its occurrence in true peritonitis: the urine at the commencement of such an attack may be natural, as in the case of Ann Draper (case 2), but I do not believe it is ever voided so clear or in such quantities as in hysteria; on the contrary, it is generally dark-coloured and scanty. How different are the symptoms in peritonitis, when we come to inquire into their real nature: we have here a rapid pulse, a flushed face, and the features pinched, the tongue becomes dry and coated, and the lips dry—in fact there is a high state of fever, which did not exist in the other case. Here again comes our test, viz., pressure of the abdomen, and we find that in this case it cannot be borne; she lies with her knees drawn up, thus relaxing the abdominal muscles, which really does in some degree relieve the pain; but her attention cannot be drawn away sufficiently to allow even of the slightest pressure without suffering acute pain. The symptoms also do not pass off with the same ease that they did in Charlotte Atkins; the cause in her case was easily removed; but in the case of Ann Draper it remained firmly seated in the shape of scrofulous tubercles in the peritoneum, which of course could not be removed, and consequently the disease proceeded. It may be asked why I suppose that the peritonitis depended upon the deposition of scrofulous tubercles in the peritoneum. There was a constant vomiting of peculiar green fluid, not of that green colour which we see in bilious vomiting, and which is so well known to all who have suffered the horrors of sea sickness; but a peculiar bright, and I may say beautiful, green vomiting, like the colour of malachite.

This I consider to be sufficient to determine the nature of the cause; I do not believe fluid of the same colour is ever vomited in any other description of cases; in addition to this, the girl was of a scrofulous aspect, and this coupled together with the knowledge of the previous disease of a joint, the vomiting during the attack, and the chest symptoms which afterwards declared themselves, would render our diagnosis tolerably certain. Unfortunately there was no opportunity of seeing the termination of the case, as she was removed into the country by the wish of her friends. But to return to Charlotte Atkins: her hysterical peritonitis, if I may be allowed to use this name, was in all probability caused by a loaded and deranged state of the bowels, accompanied with acidity of the stomach, for we find all her symptoms rapidly passing off under the use of purgatives combined with alkaline medicines.

I have said that the hysterical fit is the most striking symptom in hysteria, and undoubtedly it is so, and often in doubtful cases (for instance in certain affections of the joints) the occurrence of a fit opens our eyes to the true nature of the case.

There are, however, other symptoms, which to a careful observer are sufficiently marked without this. We then have the globus hystericus; an irregular appetite, which in some cases becomes morbid, causing the patients to eat substances which in a state of health would disgust them; there is also flatulence, which is almost always present in these cases; there are pains in one part, then in another, and the patient has a disposition to make the worst of her maladies, both present and past; she has also pain between the shoulders, shortness of breath, and cough. Now, these are exceedingly common cases, and I know of a lady at the present moment who has such symptoms, and is always frightening herself about consumption; but here the case is manifest—there is great flatulence, the stomach is loaded with flatus, it presses up the diaphragm, and consequently causes the uneasiness and shortness of breath. With regard to the cough, I cannot help thinking that it is, like many other hysterical symptoms, in a great measure under the control of the will: it is not like the cough in phthisis pulmonalis; it is not like a cough in common catarrh; it is a cough *sui generis*—a short, dry, harsh-sounding affair, more like a bark than a cough.

In cases 3 and 4 we have somewhat similar symptoms. In the case of Blake we have difficult micturition, evidently a want of will rather than of power, for the urine is voided in large quantities and perfectly clear; there is difficulty in making water, shortness of breath, globus hystericus, and all the other symptoms of hysteria. In the case of Sarah Porter (case 4) we have the same symptoms, but the catamenia have disappeared for four months. Now, in these two cases what is the cause of the complaint?—for I believe that in this as in all other cases, this is a most important question; if we can find out the cause, we are able to strike at once at the root of the evil—we remove the cause, and with it the disease. Both these patients were servants of all work, a class of beings almost invariably over-tasked; neither of them was a strong girl, and I believe that they had both been over-worked, and that this was the exciting cause of the hysteria, for in both cases, under the use of tonics combined with rest and good diet, they recovered. In the case of Sarah Porter, when the catamenia had disappeared for four months, the same treatment, together with some aloetic pills, restored her to health. In these cases we very frequently find some derangement of the uterine organs, and this often is the cause of the hysteria; thus we meet with hysteria in cases of leucorrhœa, amenorrhœa, dysmenorrhœa, and menorrhagia; and by removing the exciting cause, together with a little attention to the general health, we may remove the complaint.

That the whole system sympathises with the uterine organs is an indisputable fact and well known to every careful observer; and I think there is no fact which illustrates better than the morning sickness which occurs in the first months of pregnancy.

If, then, the stomach thus sympathizes with the uterus when it is performing a perfectly natural function, how much more may we expect the whole system to be affected when some morbid action is going on in this important part? I will not say that hysteria always depends upon a morbid condition of the uterus; such an assertion would be absurd, for there are many cases in which we can trace no connection whatever—in fact in the cases which I have quoted there is only one, in which any derangement of the uterine functions is mentioned. To enumerate all the various forms which this disease assumes would be almost impossible, for, as I have before said, it may take on the symptoms of almost any disease to which the human frame is subject. I will, however, mention one more case to show the strange forms it may assume, and contrast this with the real disease which it was aping. Eliza Simmonds (case 5) showed herself with symptoms of hemiplegia; there is apparent loss of power in the right side, both of the upper and lower extremities; and there is a history of an injury of the back received a year ago. Hemiplegia is certainly a grave symptom, but a very slight glance at this case will show that here it was only a very inconvenient one, without having the slightest danger attached to it. The urine is clear and copious; the bowels are open, skin cool, tongue clean and moist; catamenia regular. How often do we find matters going on in so comfortable a manner in disease of the spinal chord? I fear but seldom, if ever.

There is another thing also worthy of notice. When there is an injury of the spine, we generally meet with paraplegia of the parts below, either partial or total, according to the degree of injury inflicted; here we have hemiplegia. But supposing that this hemiplegia might depend upon an injury of the spine, an examination of the part being made, and we find the part perfectly straight and sound, bearing percussion on any part; and again we find that not only can she grasp things firmly with the affected hand, to save herself from falling, but she can at times stand just as firmly on the right as on the left leg: there then is a want of will and not of power; not so in hemiplegia: depending upon an organic lesion of the brain, there is then unfortunately not a want of will on the part of the unhappy patient, but literally a want of power.

In these cases of hysteria there is almost always one great insurmountable obstacle thrown in our way in the treatment: I allude to the pity and commiseration which the patient receives from her friends: to them the case appears truly alarming, and it is not often that they can be persuaded to refrain from showing their pity; but the more these patients are pitied the more intractable are their cases invariably.

In this case [illegible] "indulged with lashes witho[illegible] easily be imagined, and no doub[illegible] tolerated by her friends, [illegible] d," because believe that in most cases [illegible] gladly and willingly submit to anything to keep up the appearance of illness; they will allow you to leech and blister them, and they will swallow the most nauseous medicines which the Pharmacopœia affords; and I have read of a case in which a girl allowed herself actually to be trussed up on the operating table for lithotomy, before a whole theatre full of students.

The case of Eliza Simmonds was one which could not be much benefited by a stay in the hospital, and, as might be expected, she received but little good from it; it only served to keep up that love which in such cases they all have of wishing to be thought ill; and as long as they are indulged in this way, so long may we expect the complaint to remain, and in many cases to become worse.

In the case of Laura Schmidt we have hemiplegia but it depends upon a very different cause; here, unfortunately, it depended on an organic lesion of the brain, as was not only shown by the pathological symptoms during life, but was confirmed by the morbid appearances after death. There was want of power here: she could not stand upon the affected leg, or grasp objects with the hand of the corresponding side, neither had she any control over the muscles of that side of the face; there was complete hemiplegia, which set in immediately after the occurrence of the fit, and continued up to the last moment of her life.

Now, in regard to the treatment of hysterical cases, I do not believe we have improved much upon the plan of the immortal Sydenham; steel and the fœtid gums were then employed, and such remedies in most cases are employed at the present time, and with good effect. There are, of course, often complications requiring different kinds of treatment; but, as a general rule, steel, assafœtida, valerian, and galbanum are the principal remedies used; ether is often of great service; and the alkaline medicines to correct the acidity of the stomach, which so often exists. To enter into a detail of all the remedies which are, and have been, used in these cases would be almost endless, and altogether superfluous; I do not consider that medicine can do half so much for these patients as their friends can do almost without it, if they are inclined.

In many cases, especially in the higher classes, amongst whom I believe hysteria is very common, good country air, with cheerful society, exercise, regular hours, and attention to the state of the bowels, are all that is required to effect a cure. The less they see the face of the doctor the better; it only serves to make them think they are ill; in this respect they should have as little encouragement as possible. Some mild medicine may be prescribed—for instance: pil. galban. comp.; pil. rhei. comp. aa gr. v. omni nocte—to keep the bowels in order; and if the friends are sensible people, and will abstain from showing their pity, we may in most cases promise a recovery. But if, on the other hand, the friends will not be ruled by our advice, but will allow the patient to mope by herself and commiserate every little ache and pain she has, I then believe that all our remedies are vain; the complaint, although harmless in as far as life is concerned, is harassing and annoying to both the patients and their friends, and is under some circumstances almost utterly incurable.

Dangerous Sickness on Board H.M.S. Vesuvius.—A notice, under date Halifax, August 15, 1846, was received at Lloyd's on Saturday, stating that "her Majesty's steamer Vesuvius arrived from Vera Cruz, having on board a mortal fever, which occasioned the death of one midshipman and nine of the crew on the passage, and that thirty-nine are at present suffering from its frightful effects. The Vesuvius went round to Melville Islands this morning to remain in quarantine."

Baron Dr. Watteville, Inspector-General of Charities in France, has recently published a memoir, in which he states that there are in France 1338 hospitals and infirmaries, and that their net income exceeds £200,000.

TO CORRESPONDENTS.

W. X.—*We are under considerable difficulty to give an answer, and for several reasons we cannot publish. On the whole the Western Metropolis is perhaps the most eligible; but in any town a* home *is of the first consequence.*

A Student *intimates his wish to leave what he calls an unproductive class in the north-west of London, for a private institution, and asks our aid how he may have his money returned. He had better submit the question to his professors.*

W. M. *sends us a long account of a "hubbub" between two physicians, of no interest for our columns.*

F. S. B. *will find an answer to his question in one of the leading articles of the present number.*

A Worcester Subscriber.—*We believe that, according to the strict letter of the law, the double qualification is requisite. The regulation is frequently evaded, however. A foreign diploma would be of no service, unless obtained by* bona fide *residence and examination in a foreign university; in which case, perhaps, on a proper representation of the facts being made, the qualification might be admitted.*

We think A Constant Reader *had better communicate with the Secretary of the University of London. We cannot undertake to give our correspondent advice, as we do not know on what subjects he is deficient.*

Chemicus *will find the full account he asks for, of Dr. Gardner's amusing proceedings, in the* "Pharmaceutical Times."

*** *The pressure of engagements forces us to postpone answers to numerous correspondents.*

THE MEDICAL TIMES.

SATURDAY, EPTEMBER 5, 1846.

> "Eupolis atque Cratinus, Aristophanesque poetæ,
> Atque alii quorum comœdia prisca virorum est,
> Si quis erat dignus describi, quòd malus, aut fur,
> Quòd mœchus foret, aut sicarius, aut alioqui
> Famosus, multâ cum libertate notabant."—*Horace.*

The numerous letters which we have received, making inquiries into the constitution and prospects of the National Institute, render it a necessary duty, on our part, to enter at some length into the question. We have hitherto given a warm support to the principles of the National Association, and have advocated the expediency of establishing the Institute, because we believed that by such an organization alone could the true interests of the profession be defended, and the triumph of a liberal-minded and scientific body of men, belligerent against corporate monopoly and injustice, be secured. The principles of the Institute are identical with those of the Association: the form alone of working these principles into facts differs. The new embodiment of the professional forces was a necessary step, in the present condition of the movement, when enthusiasm had sobered into energy, impulse into a settled determination, and a resentment of wrong into an undying resolution to avenge it. This is a noble spirit, and required a form for its embodiment, which should be as permanent as its own unchangeable will. The committee have acted wisely; and the profession cannot but applaud the high-souled determination evinced in the promise of this new enterprise. We have not a doubt that every man who is warmed with a proper sense of his responsibilities, as a member of an insulted profession, and who can appreciate the honourable exertions of individuals working for the general good, and for his especial welfare, will lend his assistance to advance so great an undertaking.

There are elements in the profession which can raise the new Institute to the highest rank of scientific and social eminence. The charge has been made that a new college or a new institute, call it which you will, for the general practitioners, must be a failure—a blot upon the fair character of the profession—a degradation of its honour and conventional rank; we repudiate with indignation and scorn such a calumnious allegation. By the establishment of such an institute, the general practitioners will have adopted a mode of keeping high talent and an honoured name in their own ranks; and the old colleges will be no longer able to plume themselves, like the jackdaw of old, in the borrowed plumage of the worthy and distinguished of another class. One of the most elegant writers, sagacious observers, and profound thinkers among modern physicians, Dr. Mason Good, was a general practitioner. It was in this capacity that he hoarded his vast knowledge, formed his intellect, and matured his principles. The most learned writer on materia medica of this or any other time, Dr. Anthony Todd Thomson, was also a general practitioner! Gooch, the great accoucheur, was also a general practitioner! and what, too, shall we say to a greater name than any of these—to that of a man who has swept misery and death from a thousand habitations, dissipated the fogs of pestilence that once overhung the beautiful valleys of our country and converted them into charnel-houses of disease, disarmed the most inveterate enemy to human health that ever scourged our land, whose merits are beyond praise, as his benefits are beyond calculation—of Jenner? He, too, was a general practitioner!

There is a derisive song still extant, written by one Dr. Birch, the enemy of vaccination of that day, in which the philanthropist is stigmatized as "*a Gloucestershire apothecary!*" Since then we have seen a President of the College of Surgeons, himself the most exclusive of all men in sentiment, glad to enrol this splendid name among the luminaries of his college. But the Gloucestershire apothecary is the property of the general practitioners—his labours are the property of the universe, but his fame gems "the badge of all our tribe."

The epithet by which it was sought to disgrace Jenner has, in the present conflict of classes, been often opprobriously used to revile the whole order of general practitioners. An apostate President of a College of Surgeons and a renegade reformer in Parliament have both applied the offensive term, but in vain. Arcades ambo"—they are worthy of each other and their office.

We look forward with great satisfaction to the benefits which this new organization will effect for the profession. It is impossible to predict to what it may lead—what may be the magnitude of the changes and the importance of the advantages which may result from its operations. What it may become we know not; sure we are that there are men at the helm who, thoroughly understanding the difficulties of their position, and the wants and interests of

their brethren, are highly qualified to conduct the good vessel to a safe and permanent haven. The ultimate results will of course depend upon the support which the members of their own class are willing to give them. If *they* are apathetic or timid, not even the most sublime devotion to their welfare on the part of individuals can carry out a tithe of the advantages which would be the infallible consequences of earnest and self-sacrificing combination. Join, then, for your own preservation.

We have observed that the Society of Apothecaries have recommenced prosecutions against illegal practitioners. This is a valuable prerogative of this society, if judiciously employed. It is the safeguard of the interests of the profession, and ought never to be surrendered. Let them wield their power with discretion. We can scarcely believe that they will prosecute certificated men of the United Kingdom; we do not think that they will venture to do it in the face of the great combination in the National Institute. Besides, the time for standing close by distinctive privileges is gone by, and it were unwise of the Society of Apothecaries to risk their popularity. The National Institute invites all to join their ranks, and those who join will, of course, reap the benefit of that protection which public opinion always yields. We have made these remarks in reply to several correspondents who are anxious to know to what extent the National Institute can guarantee their immunity from prosecution. Have no fear.

The profession must maintain an organization ready to act in these critical times in defence of their rights, and prompt to assert their claims upon the Legislature. With the exception of the Institute there is, at present, no such body. The Provincial Association has lost everything but its pretension. It is not now, and never was, the organ of the general practitioners. Governed by a provincial oligarchy, there are no sympathies in its council with the mass of the members. The only grand attempt they ever made to lead in medical politics was diametrically opposed to the wishes of the profession, repugnant to sound principle, and advantageous only to the Pures who arranged the proceedings. The profession scouted the scandalous intrigue: they have been politically dead ever since, and never can revive. They have done nothing for science, nothing for medical government; but they nominate committees who make a practice of inquiring into subjects of general welfare, and at the end of twelve months report that they can do nothing.

The establishment of the National Institute will be a means of promoting kindliness of sentiment, unanimity of feeling on all matters appertaining to professional character, and combination of action for all corporate and political purposes. The notion of exclusiveness and penalty is so thoroughly imbued in professional feeling, so deeply imbedded in our opinions respecting the mode of advancing the honour and respectability of the mass, that no scheme appears that does not inculcate the necessity of firming stringent laws against unworthy practises. The last bill introduced to Parliament by the doting member for Finsbury embraced this vicious principle in its most odious manifestation. It was corporate exclusiveness incarnated, with all its hateful features of self-will and irresponsibility. Any member of the profession proved guilty of giving false evidence, &c., or of crime, might be erased by the registrar from the register, and could never again acquire a title to be placed thereon. There was no court of appeal appointed to which the registrar might be held immediately responsible. It is true, every Englishman can get justice by petition, &c.; but it very often happens that justice loiters so long on the road that the injured man is crushed by the infamy undeservedly cast upon him. We say that this was an unconstitutional and unjust power. The honourable member was, doubtless, aware of the vicious character of the bill, and, when Sir George Grey very properly shelved it, was not sorry to be so courteously extricated from his difficulties. This may account for the crocodile grin with which he greeted the announcement. Imagine Mr. Wakley the registrar, as, most probably, he would have been, what an engine of tyranny and fear he would have wielded!

It is not by penalties that the profession will be advanced in respectability, but by promoting community of feeling, amenity of manners, and general confidence. Let us heighten our professional standard by encouraging the nobler sentiments, and waking the more honourable principles of the man. Let the good be distinguished for its excellence, and the evil will retire in darkness, ashamed of its own deformity. We are quite tired of legislation upon the plan of pains and penalties. The College of Physicians tried it for centuries, and they became at last so exclusive that their exclusiveness enfeebled them, and brought them to the very verge of destitution and corporate ruin. While we shall ever inveigh vehemently against every act dishonourable to our professional character, we must deprecate a return to a retributive system of government.

The National Institute will be peculiarly adapted, by its liberal constitution and by the various qualifications of its members, to carry out these elevating and sound principles; and since a just view of the philosophy of government as well as of the wants of the profession is indispensably necessary to a governing body placed in so onerous and important a position, it becomes the members to elect such men on their council as shall guarantee, by their character, attainments, and repute, the possession of this qualification. We must not go backward; and we know of no body of men that can lead us forward with so much certitude of success as that to which we have already given our allegiance. We must have the best among the best, come whence they may.

"O beata sanitas! te præsente, amœnum
Ver floret gratiis; absque te, nemo beatus!"

We were last week advising our friends the students concerning the management of their health during the period of vacation. We treated the subject generally, and promised, this week, to conclude it more in detail.

The object of vacation, in so far as it concerns the student, is to enable him to recover the health and strength he may have lost by previous confinement and intellectual fatigue; and to give him an opportunity of leisurely recapitulating to himself the several subjects that constituted his study during the past session.

There are some who consider a holiday season as only sacred to utter idleness or unmitigated pleasure-taking. Such people have only a very imperfect estimate of themselves, or of the great objects they ought to live for. To eat, drink, sleep, and be merry, are their cardinal motives. Instead of making the animal and sensual subsidiary to the intellectual, they live just conversely; and, therefore, may be said to flourish, take root, and ripen, only in their inferior natures. Let the student who would desire to be worthy of his name, and the dignity of his calling, remember the classical adage—

"Non vivas ut edas, sed edas ut vivere possis!"

Let him observe, and apply this axiom, not only in its immediate but in its universal relations. Above all things, let him observe it in reference to the intoxicating cup! It has been truly said that this is the bane of Englishmen—and much pity is it that the more intellectual of our community are not beyond the imputation. Men, wise enough to have known better, and exalted enough to make the sin more despicable, have yet not hesitated to commit themselves to reckless dissipation. In the senate-house, wine is affirmed to have been the prime mover of the loftiest flights of eloquence and the liveliest wit; at the bar, its powers are said to have been attested in the most subtle of argument, and in the sublimest of oratory; whilst poets, from Anacreon to Byron, have not only sung its praises, but have availed themselves of its potency to add character to their enthusiasm. The dirty habits of these distinguished sources have, unhappily, infected lesser minds with a desire for their imitation. It is the young and inexperienced who are chiefly induced to copy bad manners, when these assume the air of pleasantry or the authority of fashion. It is very well to quote Horace flippantly, and sing

"Prome reconditum,
Lyde strenua, Cæcubum . . .
Capaciores affer huc, puer, scyphos,
Et Chia vina aut Lesbia."

But there is danger in these things—a danger not the less deadly because of the fascination that hides it. The inheritance of the drunkard is a train of evils more horrible than the visitants at the couch of Orestes; and often it may be fairly said of him—

"Brevis illa voluptas
Abrogat æternum cœli decus"

It rather becomes us to treat this subject in its relation to physical than moral ethics; but it so necessarily involves both, that we should have felt to have been somewhat negligent of duty had we treated it with limited signification.

As it concerns the bodily health of the student, he cannot be too careful of his dealings with that enemy which is prone to steal away his brains. The saying is a true one, but painfully true withal—"Every inordinate cup is unblessed, and the ingredient is a devil." We beg the student to bear this axiom in his memory, when, amid the smiles and welcomes of

friends long since parted with, he is tempted to express his gladness in carousal. Mind and body will both be sufferers for indulgence, and, instead of returning, a *mens sana in corpore sano*, to the scene of his intellectual and physical trial, he will probably take with him a constitution utterly unfit for the privation to be endured.

A concomitant evil of drinking is smoking. Happily, this loathsome practice is, for the most part, abolished in good society; but it still lingers with a few of the less-scrupulous adherents to an offensive old fashion. We remember the time when a cigar in a boy's mouth was considered, by the possessor, a criterion of manhood. If juveniles did but generally know how this dirty indulgence lessened the intrinsic claims to the character above noted, tobacco would soon be out of favour with candidates for a sonorous voice, a well-bearded chin, and a good stock of whiskers. *Verbum satis est!*

In order fully to enjoy the advantages of a few weeks' residence in the country, the student should make it his particular care to rise early in a morning. To hear the lark sing, and to brush the dew off the grass, is no common treat to a man who has been shut out from such indulgences for near a twelvemonth. It is a privilege not to be despised; for none can enjoy it continually, and many never enjoy it all. The liveliness and loveliness with which Nature's face looks into ours, when the sun has just risen to countenance the greeting, is only known to those who have revelled in the pleasure. But it is truly a treat, and worth any of the imaginary, dreary sacrifices, of leaving a warm bed, and washing in cold water. Besides, early rising is unaccountably conducive to health. We have no explanation to offer about the salubrity of morning air over that inhaled at any other period of the day—we only know it as one of those sturdy, substantial old facts we have heard enunciated by many an octogenarian of our acquaintance—which the whole world's experience confirms, and which no prejudiced devotee of night-time and bed-clothes has ever had courage to contradict. Take our word for it, the air that can be breathed before twelve o'clock in the day is worth double of whatever can be breathed after it.

Another point of cardinal consequence to the student, during his country sojourn, is exercise. Of this he cannot have too much, provided he make it consistent with his strength, and the sustenance he takes. Of all exercises, the most healthy and endurable is walking. It puts into action most of the voluntary muscles, and preserves a due equilibrium and energy of limb. The invalid may pursue it at any rate and to any distance compatible with his powers; and the man in robust health may make it the safest experiment upon the best energies of his frame. Riding and driving are very well in their way, but the former is by far the preferable; and the student who labours under, or has any reason to fear, a congested or sluggish liver, will find himself not a little benefited by trotting a high-actioned horse, and not rising in the stirrups. There are various athletic sports that may be pursued with great advantage. Of these, hunting, shooting, cricket, quoits, racket, and rowing, are the chief. They promote free perspiration; accelerate the circulation of the blood; hasten the respiratory function; relieve internal congestion, and tend to balance the chief organic functions. And not only this, but they are a happy diversion from other more quiet pursuits, which are generally followed by consequences the reverse of wholesome.

The student must remember, again, that his vacation is a season as well of intellectual as of physical recreation. The information with which he has stored his mind during the previous session will be very apt, in the main, to slip from his remembrance, unless he take due precaution for retaining it. However vigorously facts may have been learnt, they are not certain of retention, unless occasionally looked after. It is an idle notion to suppose that what is once learnt can never be lost. Properly speaking, nothing *actually* fades from the memory, having once impressed it. But they are *available*, not *hidden*, things of memory that are wanted. Of what use is that knowledge which is deeply buried in the recesses of a man's mind, and not extricable thence at his will? Perhaps such knowledge may never be brought to the surface again, except in the delirium of fever, when the frightened bystanders wonder what the maniac is talking about. To learn anything in such wise as not to be able afterwards to use it *on the instant of the will*, is little better than not learning at all. What signifies it that a stranger tells you he once knew such and such a subject thoroughly, but now knows nothing at all about it? The beggar is not relieved on the score of his previous possessions—and the bankrupt seldom commands credit on the strength of having aforetime deserved it. Available capital is all that is worth having or boasting of. The man whose knowledge is so deep in his head he cannot find it when he wants, is no better off than the fool in the fable, who, having buried his treasure in a field, never got a sight of it again.

We would especially commend these observations to the student, in the hope of inducing him duly to value and retain the knowledge he may have already reaped. Without submitting himself to anything like the intellectual fatigue and harass of his session, still let him not forget the desirableness of never omitting to learn something at any opportunity that offers. *Nulla dies sine linea* should be his motto; it will furnish an unexceptionable rule for his guidance in studentship and ever after! Two or three hours a day will be sufficient for recapitulating the facts gathered previously. In this manner, by a careful reference to text-books, notes, memoranda, &c., the business of the preceding session may be pleasantly gone over. Anatomy, chemistry, midwifery, and the particular manifestations of disease and its particular treatment, may, after this fashion, be brought back to the mind's eye with all the freshness they derived from the dissecting-room, the laboratory, and the bedside. And this process of repetition will not only prevent the losing of knowledge previously gained, but will strengthen its position in the memory, and add to its extent. Rarely can a subject be read, or reflected upon afresh, without the eliciting of some new truth. It is thus, and thus only, that individual knowledge becomes permanent and progressive.

It will be understood by our young friends, that these casual hints, dropped for their service, are the offspring of an anxious wish for their health and welfare. That these utterances may be productive of every good to those whom they concern, is our sincerest hope.

When the day for the reassembling of the classes shall have arrived, we shall, perhaps, take occasion to administer a few more words of suggestion.

MEETING AT QUEEN'S COLLEGE, BIRMINGHAM.

The annual meeting of the governors and friends of Queen's College was held on Wednesday, the 26th ult., in the newly-erected council-room of the Institution, for the general transaction of business. G. F. Muntz, Esq., M P., having been called to the chair, the Report for the past year was read. This, which was a somewhat lengthy document, commenced by congratulating the governors of the school on the progress which had been made, and which still continued steadily to advance. It adverted to the necessity of extended education, to the advancement of the medical profession in science as well as in public estimation, and dwelt on the necessity of a thorough knowledge of the principles of revealed truth, and the advantages of an extended classical education. The report went on to state that the Council, after long and careful deliberation on the subject, have laid down a plan of preparatory or preliminary education, in accordance with those acknowledged principles of instruction which have been adopted in our best and largest collegiate establishments.

The council, in June last, issued the following address:—

"The Council of the Queen's College, Birmingham, deeply impressed with the importance of improving the preliminary education of students in medicine and surgery, propose to establish, without delay, a junior department of their college, in order to afford to young persons intended for the professions of medicine and surgery the advantage of receiving within the walls of the college early instruction in Latin, Greek, and mathematics (with the modern languages and the sciences), from tutors of university education, carefully selected for their abilities and acquirements.

"The students to be lodged and boarded with their tutors, who will have houses provided for them near the college, and who will be responsible each for the conduct of such young persons as are intrusted to him. No particular age is fixed for the admission of students, provided they have gone through the elementary training of a classical school, and can procure testimonials of their good conduct at such school. The students in the junior department will be promoted according to their diligence and acquirements; but it is very desirable that they should be ready for matriculation and for receiving indentures of apprenticeship (where required) by the time they have reached the age of sixteen, in order that they may offer themselves for the degrees of the University of London, the diploma of the Royal College of Surgeons of England, and the license of the Society of Apothecaries, by the time they have attained the age of twenty-one; after which they may commence practice.

"As the Society of Apothecaries in London require the production of indentures from candidates of their having served an apprenticeship of five years previous to examination; and as candidates for their certificates must have attained the full age of twenty-one years; and as the course of study in the senior department of the Queen's College occupies not less than three years for its completion, it is evident that students at the Queen's College should be at least two years in the junior department, and should qualify themselves for begin

advanced to the senior department at the age of eighteen, when they will be admitted to occupy rooms in college.

"The important and valuable privilege of receiving indentures without premium is offered to the students of Queen's College by William Sands Cox, Esq., F.R.S., Dean of the Faculty."

The report then went on to state:—

"The next important subject to which your Council have to direct your attention is an especial mark of royal favour. Your Council have thankfully and gratefully received her Majesty's warrant, under the sign-manual, to issue certificates for the degrees of bachelor of arts, master of arts, bachelor of laws, or doctor of laws, to be conferred by the University of London, in addition to the privilege of qualifying for the degrees of bachelor of medicine and doctor of medicine, previously granted: thus placing your college in every respect on the same footing with King's College, London, and University College.

"Your Council have the gratification to announce that the fever wards, capable of containing seventy-five beds, in connection with the Queen's Hospital, are now completed. From the number of patients registered on its books, and especially from the liberal support given by the Staffordshire iron-masters to the charity, it has become not only of pre-eminent advantage to the public, but presents a very extended field of practical observation and instruction to the students of the college.

"A vacancy having occurred in the office of physician, that there might be neither monopoly nor exclusion, in accordance with a principle hitherto acted upon, the appointment was offered to the physicians of the Dispensary, according to seniority; and Dr. James Sandys, who pledged himself, after a reasonable time for preparation, 'to teach in the college any department of medical education, upon a request to that effect from the Council and professors, *provided such department should not be inconsistent with the province of a physician*,' was unanimously elected.

"*Museums.*—During the past year the Rev. Chancellor Law, your esteemed Vice-Principal, has made some valuable presents to the museums; and, to improve the taste of your students, has ornamented the walls with some splendid paintings. Your munificent Vice-Principal has provided for the use of the students, books, in number about 600, which include some of the best editions of the classics, works on divinity and general literature."

The names of the successful candidates for the class prizes were then announced as follows:—

A medal	Anatomy	Mr. C. W. Izod, Fladbury, Worcst.
1st medal	Mat Med.	Mr. S. Hughes, Dudley.
1st medal	Chemistry	Mr. H T. Whittell, Birmingham.
2d medal	Ditto	Mr. R. Thomason, ditto.
1st medal	Medicine	Mr. A. H Paterson, Stourbridge.
1st medal	Surgery	Mr. Peter H. Bird, London.
1st medal	Midwifery	Mr. G. Bellairs Masfen, Stafford.
1st medal	Botany	Mr. Samuel Hughes, Dudley.
1st medal	For. Med.	Mr. Alex. H. Paterson, Stourbridge.

The demonstrator's prize, Mr. Charles W. Izod and Mr. Edward Nason, Nuneaton (*æquales*); Mr. George Hodges, Ludlow, honorary certificate. The gold medals given by the munificence of the Rev. Dr. Warneford for prize essays are under consideration.

Professor Dr. Bish Davies's prize for the best clinical reports of medical cases, treated at the Clinical Hospital in his practice, has been awarded to Mr. J. H. T. V. Hughes.

Dr. Smith's prize of five guineas, for the best examination in the French language, was obtained by Mr. J. H. T. V. Hughes.

The Jephson prize of twenty guineas was also awarded to the same student, after a severe examination in all the branches of medical science.

In addition to the prizes the following rewards, offered by the Vice-Principal, have been awarded:—Mr. J. H. T. V. Hughes, £60; Mr. G. B. Mason, £45; Mr. Edward B. Machin, Derby, £5; Mr. John William Leacroft, Derby, £5; Mr. Oglethorpe Barratt, £5; Mr. A. G. H. Buckby, £5; and Mr. J. Rogerson, £3.

KING'S COLLEGE.—The subject of the "Deans Prize," to be awarded in the ensuing spring, is "the predisposing and exciting causes of Scrofula." The last prize was obtained by Mr. H. H. Salter, of Bath.

MISCELLANEOUS CORRESPONDENCE.

MEDICAL FOES.

[To the Editor of the Medical Times.]

SIR,—I have been often much surprised at the manner in which the evidence of medical men is received by the legal profession. From highest to lowest, the most profound respect is paid to their opinion, as emanating from men who are scrupulously desirous of implicitly stating the truth, and who give evidence with impartial justice to all.

This dignified position which we hold is liable to be lowered by the Hounslow inquest; for of all men none are so qualified as gentlemen of the bar to judge of evidence, and none so likely to severely censure any misrepresentation of facts to suit party or political purposes.

The welfare of the human frame under every circumstance, appertains to the medical man; and hence it was thought that the coroner's court, being a court designed to inquire into the cause of death, should properly have a medical man to preside over it. For this circumstance, Wakley, under the plea of being a medical man, was elected into that situation.

At this most unfortunate and unprecedented inquest, we have a court presided over by a man purporting to be of the medical profession, and attended by a surgeon who perverted the facts to suit the president of the court.

By the unfair and partial course which was adopted in this instance, great discredit is brought upon the whole medical profession, as it has been frequently argued that this instance shows a want of capacity of medical men to undertake such offices—a supposition calculated to act in the most injurious manner.

However, I deny that he is a medical man at the present time, inasmuch as he undertakes none of the duties of the profession. He holds indeed his diploma of the Royal College of Surgeons, but has long resigned its labours for those of medical agitation and political strife. In fact, he was, but not, strictly speaking, a medical man.

The public simply know that he is called a medical coroner, and may really believe that he is a medical man still engaged in the actual practice of his profession. In this way his unexampled conduct has inflicted a deep blow upon the faculty.

He prosecuted his inquiry till he obtained evidence which suited his purpose, when he took that and neglected the rest. He behaved in a singularly flippant manner, and excited the jury, so that even during the investigation they insulted the Adjutant. He, immediately after the inquest, attended meeting of Chartists and agitators, which explained the motive of his conduct.

Such disgraceful behaviour must be regarded by every member of the legal profession with extreme disgust: for the judge became the advocate, the inquirer the partisan, and a coroner's court was converted into a court of sedition.

Apparently the friend of the medical profession, he has shown himself as its most deadly foe; and whilst under the mask of befriending the profession and under the sanction of its name, he has lowered its dignity, debased its honour, and proved its most violent enemy.

I remain, Sir, your most obedient servant,

A CONSTANT READER.

GOSSIP OF THE WEEK.

APOTHECARIES' HALL.—Gentlemen admitted members on Thursday, August 20:—Matthew Ledger, Charles Edward Verling Goate, Frederick Augustus Kingdon, William Sedgwick Saunders.—Aug. 27: Robert William Carns.

UNIVERSITY OF LONDON.—BACHELOR OF MEDICINE.—FIRST EXAMINATION, 1846. EXAMINATION FOR HONOURS.—The following gentlemen have this year distinguished themselves in the first examination for Bachelor of Medicine at the University of London:—*Anatomy and Physiology*—Habershon, S. O. (Exhibition and Gold Medal), Guy's Hospital Littleton, Thomas (Gold Medal), University College; Hugo, Charles Sayer, University College; Eade, Peter, King's College; Savory, William Scovell, St. Bartholomew's Hospital. *Chemistry*—Habershon, S. O. (Gold Medal, Guy's Hospital; Cammack, T. A (Gold Medal), University College; Eade, Peter, King's College; Bholanoth Bose, Medical College of Bengal and University College; Hugo, Charles Sayer, University College; Littleton, Thomas, University College; Palmer, Edward, University College; Wilks, Samuel, Guy's Hospital. *Materia Medica and Pharmaceutical Chemistry*—Habershon, S. O. (Exhibition and Gold Medal), Guy's Hospital; Burgon, Joseph (Gold Medal), University College; Wilks, Samuel, Guy's Hospital; Bholanoth Bose, Medical College of Bengal and University College; Eade, Peter, King's College; Hugo, Charles Sayer, University College; Palmer, Edward, University College; Cammack, Thomas Armstrong, University College; Gopal Chunder Seal, Medical College of Bengal and University College.

WAR-OFFICE, August 28.—1st Foot—Assistant-Surgeon W. Carson, M.D, from the 85th Foot, to be Surgeon, vice J. Hutchison, who retires upon half-pay. 12th—Staff-Surgeon of the Second Class W. Robertson, M.D., to be Surgeon, vice Booth, deceased. 38th—Staff-Surgeon of the Second Class J. D. M'Ilrie to be Surgeon, vice H. L. Stuart, who retires upon half-pay. 45th—Staff-Surgeon of the Second Class F. R. Waring to be Surgeon, vice Scott, who exchanges. 46th—Assistant-Surgeon G. L. Woolhouse, from the Staff, to be Assistant-Surgeon, vice Reid, who exchanges. 85th—Assistant-Surgeon J. A. W. Thompson, M.D., from the 3rd West India Regiment, to be Assistant-Surgeon, vice Carson, promoted in the 1st. Foot.

HOSPITAL-STAFF. Surgeon R. T. Scott, from the 45th Foot, to be Staff-Surgeon of the Second Class, vice Waring, who exchanges; Staff-Assistant-Surgeon A. D. Taylor, M.D., to be Staff-Surgeon of the Second Class, vice M'Ilrie, appointed to the 38th Foot; Staff-Assistant-Surgeon G. S. Beatson, M.D., to be Staff-Surgeon of the Second Class, vice Robertson, appointed to the 12th Foot. To be Assistant-Surgeon to the Forces: Assistant-Surgeon J. Reid, from the 46th Foot, vice Woodhouse, who exchanges; J. M. A. T. Croft, vice Taylor, promoted; C. R. Matthew, vice Beatson, promoted.

MORTALITY TABLE.

For the Week ending Saturday, August 5, 1846.

Causes of Death.	Total.	Average of 5 summers.	Average of years.
ALL CAUSES......	880	808	968
SPECIFIED CAUSES...	888	892	961
Zymotic (or Epidemic, Endemic, and Contagious) Diseases............	254	201	188
SPORADIC DISEASES.			
Dropsy, Cancer, and other Diseases of uncertain or variable Seat........	95	99	104
Diseases of the Brain, Spinal Marrow, Nerves, and Senses..............	157	155	157
Diseases of the Lungs, and of the other Organs of Respiration	188	227	294
Diseases of the Heart and Blood-vessels........	22	23	27
Diseases of the Stomach, Liver, and other organs of Digestion	101	87	72
Diseases of the Kidneys, &c.	10	6	7
Childbirth, Diseases of the Uterus, &c.	10	9	10
Rheumatism, Diseases of the Bones, Joints, &c. ..		6	7
Diseases of the Skin, Cellular Tissue, &c.	1	1	2
Old Age..............	20	52	67
Violence, Privation, Cold, and Intemperance......	13	26	26

No. 365. SUMMARY. Sept. 12

PROGRESS OF MEDICAL SCIENCE,

INCLUDING CHEMISTRY AND PHARMACY.

France.

ACADEMY OF SCIENCES.

Meeting of August 31; M. Mathieu in the Chair.

Diseases produced by the Fabrication of Lucifer Matches.—M. Dupasquier, of Lyons, stated in a written communication, that the attention of the public having been of late drawn to this subject, he had been induced to examine carefully the Lyons factories, in order to ascertain how far the assertions made by various physicians were correct. He had acquired the certainty that in the city of Lyons the workmen do not present those alterations of the maxillary bones observed in other parts of France, and in Germany; but that they are subject to a mild form of bronchitis, which yields without obliging the men to abandon their occupations, even for a short time. Dr. Dupasquier attributes the necrosis of the jaw, stated to occur in the German and Parisian factories, to the presence of arsenic in the phosphorus employed in the trade.

The remainder of the meeting was consecrated to subjects foreign to medical science. The following communication made by Professor Arago, seems to us, however, to be possessed of sufficient interest to deserve a place in our columns:—

Artesian Wells.—M. Arago stated that the town council of the city of Montauban had in the course of the year 1845 ordered an artesian well to be bored, and that in July, 1846, after *eleven* months' labour, water had not yet been obtained, although the instruments had already penetrated *one hundred and seventy* metres in depth. M. Fauval, a citizen of Montauban, proposed a new and very simple method, which had been crowned with the most brilliant success, and which rested entirely upon the theory of the siphon. A hole of a few feet in depth being first dug in the ground, the screw, containing a tube, was introduced, and the hole being filled with water, around the instrument, liquid was poured into the cavity of the screw by means of a forcing pump, and the water passing rapidly through the excavation carried away with it the stones and fragments created by the unceasing action of the screw. By this very simple method the necessity for the removal of the instruments was entirely obviated throughout the whole process; in the space of *fifteen days* 170 metres were perforated, and the gush of water obtained.

ACADEMY OF MEDICINE.

Meeting of Sept. 1. M. Roche in the Chair.

The Plague.

M. Prus, the reporter, remarked, that in consequence of the vote passed at the last meeting the commission had met, and had resolved to divide the Academy on this day, in order to ascertain how far the assembly disapproved of the general tendencies of the report. The commission did not feel justified in making in its conclusions any but secondary modifications, and, if these did not satisfy the society, it was better to settle the matter at once by a formal vote and the nomination of a new commission. M. Prus, therefore, moved the following resolution:—"The Academy declares that the report may be considered as opening a sufficiently broad field for discussion, and for the statement of its opinion on the subject of the principal questions involved in the study of the plague and of quarantines."

After a short debate this motion was carried, and the meeting adjourned at a quarter after four.

HOPITAL DE LA CHARITE.

Clinical Lecture, by Professor Velpeau.

We extract the following general remarks on phlebitis and erysipelas from a recent lecture of the professor:—

Phlebitis.—This malady had been formerly divided into two forms—internal and external phlebitis; but these two denominations did not by any means present the same distinctions in the views of ancient and of modern writers. Twenty years ago, Professor Velpeau was one of the first to propose the denomination. External phlebitis refers not to inflammation of the exernal veins, but to phlogosis of the external coat of the venous structure; and internal phlebitis does not indicate inflammation of the deep-seated veins, but inflammation of the internal coat of any venous canal. This distinction is of the greatest importance in the history of the malady; external phlebitis may be looked upon as a trifling disease in comparison with the other form of venous inflammation. The great danger incurred in the latter evidently depends upon the formation of pus and its passage into the circulation; an occurrence which is sometimes, though too seldom, prevented by the production of adhesions in the vessel by which the purulent matter is incarcerated. The prognosis of these two varieties of the same affection being so widely different, it is useful to recal to the mind the chain of symptoms by which each of them is characterized. In external phlebitis, a swollen, red, and painful chord may be seen and felt along the course of the vessel, without any symptoms of general disturbance. Internal phlebitis, on the contrary, is ushered in by shivering, frequency of pulse, and adynamia. The course of the vein may sometimes present the hardness noticed in the other form, but it is never so evident; a fact readily accounted for by the knowledge of the seat of inflammation. In a word, in external phlebitis the local symptoms are very well marked, and the general symptoms indistinct; in internal phlebitis the signs of general suffering of the system first awake the attention of the physician, before the local symptoms have made their [illegible]. The prognosis of internal phlebitis requires still a greater degree of gravity when it is recollected that the means of arresting its progress are yet to be found. Many methods of treatment have been proposed, none of which hitherto have yielded satisfactory results. Amongst these methods we may mention compression of the vein—a plan which remains ineffectual on account of the diffused nature of the inflammation; and division of the vein, which has also been thought of: this is sometimes a dangerous step, predisposing to the production of the disease it is intended to cure. We can easily conceive what would be really useful, but we cannot so readily find an agent to accomplish it: what is required is a drug which, by its presence, would neutralize the bad effects of the passage of pus into the blood. In the present state of science we can only say that most of the persons attacked with internal phlebitis are lost. As to the external form, it is cured by local antiphlogistic measures: resolution is often obtained, but sometimes an abscess forms around the inflamed vessel.

Erysipelas.—The cases of erysipelas observed in the wards during the past season have been twenty in number: five of the patients entered the hospital suffering from simple erysipelas of the head, and were all cured. The fifteen others had erysipelas in the hospital as a complication of wounds or operations; of these fifteen, eight died; hence a remarkable difference of prognosis should be made between cases of erysipelas complicating wounds, and the idiopathic variety. Even when it attacks the head, it is a less dangerous disease than is commonly supposed, and may generally be cured in the space of eight or ten days, whatever may have been the treatment employed. This assertion will, doubtless, be considered strange, but we purposely insist upon it, because many physicians labour under the delusion that they cure erysipelas by various methods: one will recommend leeching and venesection; another has unbounded confidence in emetics; and in our opinion all are in error, merely because they have not noticed the habitual duration of the disorder when no treatment whatever has been resorted to. In two of our latest patients the disorder lasted four or five days. Another was admitted about the same time; we gave her an emetic, but we do not flatter ourselves that we cured her—most assuredly she recovered spontaneously. The object of the treatment is merely to curb the severity of the symptoms, and to prevent the occurrence of any dangerous complication; but it is a very difficult question, and a very doubtful one, whether by any treatment the natural length of the malady can be shortened; indeed it is impossible to say beforehand what will be its probable duration. A woman was lately admitted who twice previously had been similarly affected: the disease lasted the first time twelve, the second fourteen days; she entered our wards, and in four days, without treatment, she was well. Had we used any drug we should, of course, have attributed to it, and erroneously, the rapid cure of our patient.

Treatment of Erysipelas.—Such is Prof. Velpeau's opinion of the inefficacy of all treatment of this affection. But this discouraging scepticism is not prevalent amongst French practitioners; at the Hospital St. Louis, M. Jobert employs with much success, independently of revulsion on the

intestinal tube, local [illegible] of nitrate of silver ointment, in the [illegible] of ʒj., ʒij., or ʒiij., to ℥j. of lard. [illegible] natory symptoms —namely, the pain an[illegible] n—are rapidly subdued, the epidermi[illegible] y, and the skin resumes its natural [illegible] This ointment M. Sabat also applies in many cases of chronic or even acute orchitis, with much advantage.

TREATMENT OF COLICA PICTONUM.—Dr. Gendrin, physician of the Hospital of la Pitié, whose researches on saturnine intoxication have attracted of late years much attention, states that colica pictonum, uncomplicated with cerebral symptoms, always yields in a space of time varying from three to six days, to the internal exhibition of sulphuric acid, in doses of ʒj. to ʒjss. daily, diluted in a quart and a half of water. The results of the treatment are not so rapid or so satisfactory where the skin is covered with a layer of metallic residues; these shou[illegible]y with alkaline baths at the same time that the acid is given internally. M. G. was led to the use of sulphuric acid by the knowledge of its chemical action on saturnine salts, which it renders insoluble, and, therefore, inert. He also thinks that the most efficient method which can be adopted to preserve from the disease the workmen engaged in the preparation of white or red lead, is to oblige them to drink two or three tumblers of sulphuric lemonade in the course of the day; to perform frequent ablutions of the hands and face; and to use in the factories a dress different from that which they wear out of doors. M. Bertini, physician of the Hospital of Saint Lazare at Turin, and MM. Priesso and Solari at Genoa, have obtained from the application of Dr. Gendrin's method the most decided benefit.

MEDICAL SOCIETY OF EMULATION.

M. LARREY, President.

WOUNDS INFLICTED DURING DISSECTION.—M. Blatin presented to the Society, gloves, made of a thin sheet of caoutchouc, destined to guard the hand of the anatomist against injury from wounds during dissection, or from the contact of noxious substances in *post-mortem* examinations. The tissue of the gloves is so fine as not to interfere in any way with the movement of the fingers, and to diminish only in a very slight degree the sensation of the hand.

UTERINE DISEASE DURING PREGNANCY, BY M. FORGET.—The history of the influence of fibrous bodies and of polypi on the progress of pregnancy, and on the function of parturition, has been the object of Dr. F.'s researches. With regard to fibrous productions, their danger may be considered to be in proportion to their size and to their number: when their volume is small they do not materially interfere with the functions of the gravid uterus, nor prevent its retraction after accouchement; the same innocuity will be observed when the fibrous bodies lie under the peritoneum, by which they are alone attached to the womb. These fortunate circumstances are not, however, always met with, and when situated in the uterine walls, they often become a cause of abortion, and always render labour difficult, and may produce fatal hemorrhage. During the last stage of pregnancy the increased phenomena of nutrition, occasioned in the uterus by the development of the foetus, explain the rapid growth of the tumours, and the consequent severity of accouchement. As to polypi, M. Forget considers as a demonstrated fact that polypi, even very large, situated in the womb or in the vagina, do not prevent impregnation, and cause but little uneasiness during pregnancy: they seldom produce abortion. When the polypus remains in the womb after delivery, the danger is great for the mother; but it is the life of the child that is endangered when the polypus has descended into the vagina. In the latter case the surg[illegible] should n[illegible]t operate until the womb has resume[illegible] natural dimensions; but when the tumour o[illegible]pies the uterine cavity, and abundant hemorrhage is present, surgical art must interfere for its removal.

IMPERFORATE ANUS.—On August 23, a seven-months' child, aged twelve hours, was brought to the Hôpital des Cliniques, and admitted into the surgical wards. Since its birth the infant had constantly vomited stercoraceous matter; the anus still existed, but at a depth of eight lines was obliterated by a transversal membrane. Examination with the finger did not permit the surgeon to detect the presence of any swelling by which he might be guided in any attempt to open the intestine. A female catheter was forced through the membranous partition, and readily penetrated eighteen lines deeper, without, however, bringing away any meconium, or any fluid. M. Voillemier—feeling convinced that some other impediment existed to the progress of the contents of the digestive tube besides the imperforate anus, and uncertain of the seat of the anatomical alteration—did not perform M. Amussat's operation for lumbar anus. The patient died on the same day. On dissection, the stomach and intestines, in a length of eighty-five centimètres (two feet five inches), were found in a state of considerable distention, chiefly occasioned by the presence of gas. The rest of the intestine (ninety-two centimètres—two feet eight inches) was very much contracted, having only the volume of a quill, and contained a thick, viscid mucus. These two portions of intestine did not continue into each other, but were separated by an interval of two inches. Two other portions of the intestine also floated freely in the abdominal cavity; one was two inches, the other three and a half, long.

CONVULSIONS AND PREMATURE DELIVERY.—On the 12th of March, 1840, a woman was brought to the Hospital St. Louis, in a state of insensibility, and admitted into M. Malgaigne's wards. She was perfectly unconscious, but affected with violent convulsions attended with distortion of the face and loud cries. The convulsions were continuous, and affected both sides of the body without any relaxation whatever; the womb al[illegible]took of the convulsive state of the muscular system; the uterus could be felt through the abdominal wall, hard and contracted; no vaginal discharge was present; the os tincæ was completely effaced, and the head of the child was recognised. But a new order of convulsions, of an epileptic form, appeared twice during the first three hours after admission; the head was dragged backwards; the face grew first pale, and then livid and purple; the eyeballs were drawn upwards, and the general character of the convulsions of the extremities became quite different from what they had previously been: after each attack, the duration of which was about five minutes, a period of coma followed; twelve ounces of blood were taken from the arm, but venesection was followed with two other fits: the pulse marked 130; the fœtal heart and placental murmur were distinct, and the neck of the womb dilated to the size of a two-franc piece. The accouchement took place spontaneously during the convulsions, and without the amniotic fluid being discharged; the ovum was expelled entire; the child, a stillborn fœtus, fourteen inches in length. The loss of consciousness of the mother persisted for twenty-four hours, but the convulsions did not reappear; and it was only four days after her admission that she was able to give a lucid account of herself. She had been confined four times, and two of her children had died of convulsions shortly after birth—one being born at seven months and a half. She had never before had convulsions. One of her sisters was subject to fits before she first menstruated, and another had given birth to six children, who *all* had died of convulsions: the patient was well on the 22nd of March, and was discharged.

DAN. M'CARTHY, D.M.P.

America.

CHANGE OF COLOUR IN A NEGRO.—Dr. Savage [illegible]ds a case in the "American Journal of Medical [illegible]nces," in which a negro, a nati[illegible] of the Grebo tribe, inhabiting Cape Palmas and its vicinity, in North Africa, underwent a remarkable change in the colour of his body. The complexion of this man's father was decidedly black, that of his mother "*yellow*"—the two extremes observable in the tribe, and between which there is found almost any variety of shade. His own natural complexion was black, not presenting quite so deep a hue as his father's, being a shade or two lighter, perhaps, than the blackest. He was about twenty-five years of age; rather under the average height of his tribe, measuring five feet and four and a half inches; his proportions were good, muscles well developed, and he had always appeared to be in fine health. In the beginning of March, 1844, in the evening, soon after retiring from his work, he was suddenly attacked with an acute, deep-seated pain in the head, back of the forehead and eyes, accompanied with vertigo. This was soon followed by a violent ague, and a distressing spasmodic action of the muscles of the throat and chest, attended by a suspension of the functions of the mucous membrane lining the laryngeal and pharyngeal passages. He felt an extreme dryness in the fauces, and as if a bone were lodged in the throat, depriving him of the power of free deglutition and respiration. The pain in his eyes was aggravated during the night to an agonizing degree; the lids convulsively closed, not leaving the power of reopening them. This was accompanied or succeeded by a flow of tears so profuse that the attendants thought the *balls must have bursted*. These symptoms continued for a week with more or less severity, except the ague, the paroxysms of which were of daily recurrence. The intensity of the symptoms generally during the period varied with the temperature of the surrounding air. The heat of a fire and of the direct rays of the sun was intolerable, and, whenever so exposed, he was instantly driven to seek a cooler position. During the first night of the attack, an extremely annoying and painful sensation was experienced immediately under the skin, represented to be like the pricking of needles, and followed by an intense itching. The numerous papillæ of the skin then enlarged and gave to it a feeling of cutis anserina. This eruption appeared first on his neck, and thence rapidly spread over his body, and continued also through the week, varying in degree with the aërial temperature. By the eighth day there was a subsidence of the symptoms generally, and the process of desquamation began. This continued three days, during which time the cuticle came off freely, in pieces of half an inch in diameter, [illegible] to a very minute furfuraceous exfoliation, [illegible]uld be easily removed by the hand or other m[illegible]s. His body now had lost its identity, and, instead of the complexion of a negro, presented a dingy yellow, like that of the sole of the foot after having been exposed to the action of salt water.

After this change, the dull yellowish white characteristic of the eye of the negro was lost, and the clear white or bluish tinge of the eye of the white man became present. About a month after the first attack the same symptoms recurred slightly, and desquamation again proceeded. The cuticle thrown off on this occasion was thinner than that on the former, and the colour resulting (which still partly continued when the report was drawn up) was not really white, except on the back of the hands, on the wrists, feet, and ankles. The skin on the hands was free from that coarseness and corrugated appearance peculiar to the race, and was delicate and soft, showing through the new cuticular medium the blue veins beneath. On the lower part of the back, on the abdomen, front of the thighs, and calves of the legs, there was a dark hue, much increased, however, by the thick black hair on those parts, which appeared to be but little, if at all, changed. On most other parts of the body there was a dull white; in some places a decided white, with considerable delicacy and softness of skin. His aspect was not that of a mulatto, but—with the exception of his decidedly marked negro features, and the crispness of his hair—that of a white man. He was extremely sensible to the heat of fire and the sun. His face and feet were inflamed, and the latter much swollen from the influence of the sun. The soles of his feet and palms of his hands were very tender, making it painful for him to walk or handle rough objects. His toe and finger nails showed the mysterious influence at work in his system. The process of detachment was regularly though slowly going on; a distinct line of

demarcation was visible between the new and old nails; the former having advanced about one-third the distance. The posterior portion of the latter presented a flaky appearance, showing most clearly their laminated structure. The new portion, in its flatness, clearness, and delicacy, exhibited a striking contrast to the old, which was convex, dull in aspect and thick. The hair was not much changed. The border only of the hairy scalp came off, the superior portion, cuticle, and hair remaining unchanged. Some weeks afterwards the hair on the surface generally became white. No other change had occurred except that produced by exposure to the sun, in consequence of which the cuticle had cracked in several situations, especially in the feet. Three months from this time, on again examining the patient, numerous small spots of a chestnut-brown colour were found on different parts of his body. These were unattended by any elevation of the cuticle, and increased more in number than in size, running into patches in different places which were a shade or two darker than the recent spots. They appeared first upon the wrist, where they had become so numerous as to reach in patches upwards, to a distance of six inches or more. Their appearance was then on the back of the arm, head, and neck successively. A continuous narrow line of black extended from the hair on each temple down to the cheek, which, in contrast with the adjacent white skin, presented the aspect of whiskers. Spots and patches of a dark brown appeared also on the back. The hands, with the exception of a few spots on their back, were white. The front of his thighs, his calves, and shins were thickly spotted, and the complexion of the skin generally seemed to be a shade or two darker, not by the tanning effect of the sun, as is seen upon the white man's skin, but evidently more deeply seated. He said that bathing in the sea so far macerated his skin that he could rub off the cuticle and restore the whiteness. Two months after, the general shade of his skin was somewhat darker; and in many places, where before there had been spots only, patches now appeared. The patches that existed at the last examination had considerably increased in size, and were of a decided black, even more so, it was said, than his natural complexion. Spots were now seen scattered over the whole surface, varying in shade, from a light brown to a black, according to their age. In all cases the colour was dull, wholly devoid of that oily and shining appearance usual in all healthy and cleanly negroes. The calves of the legs, the thighs, the abdomen, back of the arms and neck, sides of the forehead, and upper lip, were black, though presenting in various places irregular patches of white.

The colour of the hair was restored with that of the skin, and the patient said that the white hairs fell off and the black appeared as the change in the cuticle advanced. Four months after, when the case was last seen, the dark spots were progressively extending. The man's health was excellent

REMARKABLE CASE OF INJURY OF THE HEAD.—Dr. Forman, in the "American Journal of Medical Sciences," records a case in which a young man, aged 17, while preparing for a shooting party, accidentally discharged his gun, and the contents (duck shot) passing the left side of his head, tore away the ear above the concha, together with a portion of the scalp and temporal muscle, making a frightful wound in the integuments, and producing a compound comminuted fracture and depression of the lower and middle part of the parietal bone. He leaped into the air and fell upon his face on the ground. He was insensible, convulsed, and bleeding profusely from the wound. There was some hemorrhage also from the nostrils, so that, perhaps, he lost in all a quart of blood. His pulse was imperceptible. Before the arrival of medical assistance, however, reaction had taken place. He had vomited several times, and spoken frequently, exclaiming, "Boys! Boys!" and once, when addressed by name, he answered "What?" The wound was occupied with coagulated blood, and a small quantity of brain; the fracture comprised a little more than an inch in width of the inferior part of the parietal bone, and was bounded posteriorly by a line, extending from the centre of the meatus auditorius externus to nearly a right angle with the sagittal suture, from which there proceeded under the integuments anteriorly two fissures, including between them two deeply-depressed fragments, the inferior, or that next to the squamous suture, being much the larger. The blood was washed off, the chasm filled with lint, and a bandage applied, during which the patient evinced great sensibility, exhibiting signs of pain on the slightest touch of the parts. After the completion of the dressing, his pulse was small and feeble. Through the remainder of the day and night, and the following day, he was partially comatose, though easily aroused; his breathing was slow and at times stertorous. He vomited occasionally, and the matter ejected was mixed with blood. His pulse was slow, beating but forty-three strokes per minute, and very feeble. The pupils nearly natural in size, and not devoid of sensibility to light. Temperature of the skin below the healthy standard. On the evening of the second day, after a careful examination of the fracture, it was agreed that a portion of the bone, large enough to allow the use of the elevator to restore the depressed pieces to their natural level, should be removed by means of "Hey's saw," while symptoms should dictate the treatment to be afterwards pursued. By free use of the saw, a somewhat triangular portion of the parietal bone, about an inch in its longest direction, and three lines long at its base, was removed. The larger fragment was elevated to its proper position, while the smaller, of an irregular quadrilateral figure, about eight lines by four, beaten down upon the dura mater, and entirely detached from its natural connection, was removed. About three lines above the superior edge of the elevated fragment, the pulsation of the brain brought into view, through a rent in the dura mater, another piece of bone, a scale, almost entirely from the inner table of the skull, of an irregular figure and half an inch in its greatest diameter. On the removal of this a gush of brain followed, which continued to flow, until half a wineglassful was computed to have been lost His pulse rose immediately to eighty strokes in a minute, and the night was passed in alternations of coma and restlessness. The wound discharged so much blood and brain that the dressings and pillow were saturated with them.

On the second day after the operation, the adhesive straps used to secure the dressings were all found detached, and a large fungus cerebri was seen projecting through the aperture in the cranium. This substance was not composed of *pure* brain, nor covered by any of the membranes of that organ. Neither was it formed of coagulated blood, as Mr. Abernethy supposed some of these productions to be; but it was an organized body, springing from the brain, and subsisting by its own mode of nutrition. The whole surface of the wound, the pericranium, the temporal muscle, and the edges of the scalp, poured out an abundant secretion of pus. The ulcer was carefully cleansed, and dressed with simple cerate, while compresses wet with lime-water were applied to the fungus after the manner of Sir A. Cooper. The same evening consciousness returned to a certain extent, and the patient answered questions put to him. On the 5th of October, nine days after the accident, the patient had convulsions of the neck and face; and on the 6th, consciousness returned, but motor hemiplegia of the right side supervened, and he entirely lost the power of articulation, which he never regained. On the 8th there was an escape of fetid gas from the wound in considerable quantity. The bones in the neighbourhood of the wound were found necrosed. The fungus continued to increase On the 14th a ligature was put round the base of the fungus This came away on the following day without diminution in the size of the fungus *Consciousness continued perfect.* On the 17th the fungus sloughed off to a level with the skull, and was removed with the dressings, but so rapid was its growth that before they could be reapplied it had sprung a quarter of an inch. On the 20th the patient had passed an uncomfortable night, having slept but little, and being extremely restless when awake. *Consciousness perfect;* eyes and countenance natural. Head free from pain and every uneasiness, even when rapidly rotated. Skin heated, and tongue dry and brown. Pulse 120, and weak· Wound discharging an abundant [illegible]. Fetor much lessened. Fungus greatly enlarged. Its upper portion had the appearance of the cineritious part of the brain, while the lower was [illegible] tender, and fibrous. The dura mater much thickened, very vascular, and almost as firm as cartilage. He continued much in the same state until the 28th of October, thirty-three days after the accident, when he was in the following condition:— Had scarcely slept during the night. Countenance, however, pretty good. Pulse 100, distinct, and moderately full. Skin cooler than yesterday. Mouth and tongue parched. No appetite, and very restless. On removing the dressings the fungus was no longer to be seen, but the bones, denuded and dead, with the opening in them unobstructed, came directly into view, permitting a more extensive survey of the interior of the skull than, perhaps, was ever before made upon living man. The extent of the cavity antero-posteriorly was estimated at four inches. Transversely the falx-cerebri was visible, and bounded the view in that direction. The outline of the apophysis of Ingratius was seen anteriorly, and that of the edge of the tentorium posteriorly. Pending from the bone, near the posterior margin of the cranial aperture, was a flap of the dura mater, hanging like a curtain into the cavity, and shutting off in a degree the prospect towards the occiput. This may have been the remnant of the more fibrous part of the fungus, as no portion of it was found in the dressings. The floor of this cavity was formed of a thin stratum sloping inward and downward toward the cerebral ganglia, from the lower edge of the aperture in the cranium, at an angle of about forty-five degrees. Some shreds of the dura mater, detached in part from the internal surface of the skull, were seen hanging into the cavity, as also a few vessels stretching across its walls in different directions, chiefly, however, along the falx. His eyes were glassy and unsteady. His head was occasionally agitated by an involuntary rotatory movement. The parotid gland, on the injured side, was very much swollen. *Sensibility and consciousness perfect.* No pulsation of the brain.

On November 1st he saluted Dr. Forman with a smile; but on the 2nd he recognised no one. Countenance hippocratic. Respiration short and hurried, voice guttural. Muscular agitation of the whole of the left side, particularly of the arm, violent. The muscles of the paralyzed limbs were affected by a tremulous shudder. Their contractions were not sufficient to move the members to which they were attached. Lower jaw moved as in mastication. Skin hot and purple. No discharge from the wound, which was of a leaden colour. Bladder not evacuated for the last twenty-eight hours. A catheter was introduced, and rather more than half a pint of urine drawn off. He manifested great sensibility of the urethra during the introduction of the instrument. As the day advanced, the muscular movements subsided; he moaned incessantly; his skin continued purple and intensely hot over the thorax; his pulse became scarcely perceptible; and at two o'clock he ejected, by a sort of regurgitative effort, a mouthful of yellow fluid, threw back his head, and expired.

Autopsy twenty-two hours after Death.—The inferior edge of the cranial aperture was situated at the point of intersection between two lines drawn, the one perpendicularly to the external meatus auditorius, and the other horizontally backward, from the external angular process of the os frontis. Extending upward and backward, its entire length was about an inch and a half, and its width not quite an inch. By removing a circular piece of bone, in advance of this, for the purpose of inspecting the dura mater *in situ*, it was found to be detached as high up as the origin of the temporal muscle down to the base of the skull, and forward as far as the frontal bone. One part of it hung down into the cavity, very much thickened, and gangrenous. The upper half of the cranium being removed, nearly half a gill of sero-purulent fluid escaped through a rupture in the dura mater covering the anterior lobe, which became flaccid and collapsed. A small quantity of

purulent matter was also found beneath the dura mater on the under side of the medulla oblongata. At the surface of the brain, next to the cranial aperture, it was completely destroyed to the extent of two inches all around. The lower half of the middle lobe was also entirely destroyed, with the exception of a thin stratum at its base, not more than a quarter of an inch in thickness, meninges included, which was also diseased. Introducing the finger into the cavity and exploring it, it was found to extend the whole length of the lateral ventricle. Extending the dissection by removing the upper part of the hemisphere above the corpus callosum, two sinuses were discovered, leading from the main cavity. One of these extended into the anterior lobe, was about two inches in length, and half an inch in diameter. It was the orifice of this sinus observed before his death, and from it came the pus which escaped through the dura mater. The other sinus was situated in the posterior lobe, extending upward and backward very near to the surface, just above the torcular herophili, an inch and a half in length. In the bottom of this sinus were found two pieces of lead, very much flattened and indented together, about equal in size to one of the shot with which his gun was charged when he received the wound. A spicula of bone, about the size of a mustard seed, was also found here. In the posterior lobe there was not more than a cubic inch of healthy medullary substance, most of it being entirely destroyed, and the rest converted into a semi-purulent amorphous mass. About one-third of the anterior lobe and two-thirds of the middle were in the same condition. Examining the lateral ventricle, the corpus callosum, as far as the *raphé* on the injured side, was destroyed. The septum lucidum and anterior part of the fornix were also destroyed. The hippocampi were too much diseased to be distinguished. The upper half of the corpus striatum was very much softened; on scraping this off, however, the diverging fibres of the corpus pyramidale were beautifully displayed, spreading out through the grey substance of the ganglion, resembling the striated appearance of our common marine shells. With the exception of the commissura mollis, the thalamus was more healthy. Between the two thalami there was no connection. The veum interpositum and choroid plexus of the lateral ventricles were destroyed. There existed, therefore, a communication between all the ventricles and the wound. The right hemisphere, with the exception of a convolution above the corpus callosum (which was "curdly" and friable, and those around its lower external surface, which were inseparably adherent) was healthy. The cerebellum and parts described on the base of the brain were all healthy except the corpora albicantia. Between the infundibulum and pons there was nothing to be found like a rounded body or an eminence. Such was the condition of the parts when dissected; the dissection, however, owing to the softness of the brain when first removed from the skull, was not completed for several days, and during this time it was preserved in alcohol.

To the above narrative Dr. Forman appends the following judicious remarks:—

"To all who witnessed this case it was a matter of great astonishment that the patient should have lived so long, preserving his mental and corporeal functions so little impaired. The right side was paralysed only as regarded its motion, and that imperfectly. Its sensibility was very little if at all impaired. These phenomena would corroborate the conclusions that the origin of the locomotive influence is in the anterior columns of the cerebro-spinal axis (inasmuch as they were the parts chiefly injured), while sensibility resides in the posterior.

"How was the abolition of the power of speech to be explained? Was it owing to the diseased condition of the cornu-ammonis and temporal lobe, in which Foville locates the seat of this variety of muscular motion?

"In consequence of his entire inability to articulate, and the paralysis of his right arm, it was impossible to ascertain the exact degree in which he retained his intellectual faculties. Signs were his only media of communication, and these, it must be confessed, were not always the most expressive in representing the ideas he wished to convey. From the eleventh day after the receipt of the wound, until the second or third before his death, he gave every indication of consciousness and reason. He recognised his friends and took pleasure in their society. Among those who watched and nursed him, he preferred the services of some to those of others. Failing on one or two occasions to make known his wants by such signs as he used, he attempted to write them with his left hand, but after several illegible efforts he gave it up in despair. At another time a proposition was made to him in writing, one word in which he could not decipher, when, pointing to it with his finger to have it explained, he expressed his approbation of the proposal, and gave it his ready assent.

"It is greatly to be regretted that the extension of the injury to the different parts of the encephalon cannot be determined in the order of its invasion of them, and the succession of the symptoms in their relation to this order, as the case of Mr. B. would then be one of the most instructive, as it now is one of the most extraordinary, which the annals of medicine record. On the seventh day from the occurrence of the accident, the secondary symptoms consequent to it were first manifested; and, by supposing the irritation from the wound at this time to have just reached the hippocampi, the opinion of Foville will be thus far confirmed, for on the evening of that day articulation became embarrassed, was entirely suspended on the next, and never afterwards recovered. On the ninth, convulsive movements of the muscles of the face and neck occurred, and on the tenth, motor hemiplegia seized the patient, both of which are readily explained upon the supposition that at this time the corpus striatum became involved. With speculations upon the possible, however, Science will not be satisfied. Her stern demand is facts, and having given these, I leave each one to draw such conclusions from them as will be most satisfactory to himself."

ORIGINAL LECTURES.

A Course of Lectures on Hernia,

By JOHN FLINT SOUTH, Esq.,
Surgeon to St. Thomas's Hospital, and Professor of Surgery to the Royal College of Surgeons.

(Delivered in the Theatre of the College, and revised by the Professor for the MEDICAL TIMES.)

LECTURE V.

(Continued from page 385.)

Operations for strangulated inguinal rupture: Incision to be commenced high up; division of superficial fascia and cremaster muscle; difference of thickness of coverings; mode of opening the sac division of stricture; directions in order to avoid blood-vessels; Sir Astley Cooper's rule; procedure when the stricture is in the canal or at the internal ring. Femoral Ruptures: Definition—internal femoral rupture; relation to blood-vessels; cases in which more than one femoral rupture exist; co-existence of femoral and inguinal ruptures.

External Femoral Rupture—its rarity; its position; femoral rupture in front of the femoral vessels; other varieties of femoral rupture.

The cases in which the rupture sac has been found behind a hydrocele—first noticed by Mr. Thomas Blizard, and subsequently by Sir Astley Cooper and Mr. Henry Cline, and which have since been found more frequent than supposed twenty-five years since—appear to me readily explicable in the same way. A hydrocele exists, a rupture descends till it reaches its upper part, and the disposition to protrusion still continuing, the sac begins to drive down behind the hydrocele, and probably as it lengthens rolls down with it the back of the distended vaginal tunic, which thus forms a second peritoneal covering in front of the rupture. Or a rupture may first exist, and a hydrocele subsequently forming may, as it grows, ascend in front of the rupture sac, and thus the same condition of parts be produced, with the mere difference that the hydrocele ascends before the rupture, instead of the rupture descending behind the hydrocele. The fluid of the hydrocele does not necessarily remain: in Mr. Thomas Blizard's case it was absorbed; but in Mr. Henry Cline's, which I saw operated on, it poured forth when the vaginal tunic was opened.

These are the only kinds of rupture in which a double peritoneal sac can exist. When the adherent neck in a congenital rupture descends vertically into the vaginal tunic, then the double peritoneal sac is complete all round; but when the rupture descends behind a hydrocele, then the peritoneal covering is double in front only, and not behind. In both cases, however, the testicle will be exposed in the course of the operation.

Many swellings of the scrotum, or rather of the parts which it contains, are liable to be c[onfounded] with ruptures, either just after their protru[sion through] the external ring, or when they have d[escended] into the scrotum. The distinction, however, is generally not difficult, often even with a slight examination, and when taken in connection with the previous history of the case, and the constitutional symptoms. Hydrocele of the vaginal tunic of the testicle, although somewhat of the same form, especially if of large size, and as occasionally extending up the spermatic cord to the ring, and even into it, is distinguished by its transparency, by its first appearing at the bottom of the scrotum, and gradually ascending in proportion to its bulk; but I have never seen a single instance, however high a hydrocele might ascend, in which it was not possible to nip the cord between the top of the distended vaginal tunic and the external ring, and so ascertain that it has not any communication with the belly. Of course it undergoes no alteration in size, whether the patient be standing or lying down; neither does it dilate or increase on coughing or any other effort in which the bowels are acted on by the abdominal muscles. One kind of hydrocele, which is, however, far from frequent, is liable to mistake; it is the congenital hydrocele, in which the vaginal tunic not having closed at the internal ring, the fluid contained in it will swell out the hydrocele sac in the erect posture; but, flowing back into the belly when the person lies down, the swelling disappears. But this may be without difficulty distinguished, because, if it were a reducible rupture which returned into the belly on lying down, the fingers placed against the ring would, in most cases, prevent the protrusion of the bowel when the patient stood erect; and consequently there would be no enlargement of the scrotum. But in congenital hydrocele, though pressure were made on the ring, the fluid would ooze through the mouth of the sac into the hydrocele sac, and though not so quickly, yet as certainly at last would distend to its former sizse.

The more rare form of hydrocele, that of the spermatic cord, is more liable to be mistaken for a bubonocele, or inguinal rupture, which has just passed through the external ring. I have seen two or three instances in which this mistake has been made, and an operation thought to be requisite. A curious circumstance with respect to hydrocele of the cord is, that the person sometimes says it has appeared suddenly and after additional exertion. Such was the statement in reference to the last two cases I saw, one of which was under my own care very recently. It would hardly seem possible that it should have been produced at once, or even in course of a few hours, but the patients were positive about it. The appearance of such cases very closely resembles a bubonocele, but, as in common hydrocele, the spermatic cord may always with a little management be grasped above it, and its complete independence of the cavity of the belly ascertained.

Varicocele may be mistaken for rupture, especially if the veins be very much enlarged. Like a rupture, it increases in the upright posture, and mostly disappears on lying down. But if the fingers be placed on the ring, and the patient directed to stand up, the swelling not only reappears, but is of greater size than before, because the pressure, though insufficient to prevent the blood passing through the spermatic artery, is sufficient to prevent its return by the veins, which consequently become largely distended. This quick and increased bulk readily distinguishes varicocele from hydrocele, from which it is still further discerned by the knotty rope-like and general thickness of the whole cord from the testicle upwards, and by its want of transparency.

Thickening of the cord from chronic inflammation, and suppuration in the cord, which last is extremely rare, are said to be capable of mistake with inguinal rupture, and also enlargements of the testicle of any kind are said to be so too; but mistake of either of these conditions can only arise out of great carelessness.

An arrest of the descent of the testicle at the abdominal ring may be mistaken for rupture, but may be distinguished with a little management and tenderness by pressing the finger and thumb upon the cord between the testicle and the ring. Rupture may be complicated with hydrocele, as I have already mentioned; and the rupture sac may either descend only to the top of the hydrocele, as in Prep. No. 1,333 of the College Collection, or even not so low; or it may pass down behind it, as I have shown. I may however observe, that in a person of lax habit, a heavy hydrocele, constantly dragging by its weight upon the cord, would certainly predispose to an oblique rupture, as it would be constantly pulling that part of the cord fascia arising from the inner ring, and thus produce a little hollow, into which, by the ordinary pressure of the abdominal muscles upon the bowels, the peritoneum would be forced, and thus the beginning of a rupture sac be formed.

The absence of all symptoms of strangulation, or of those accompanying peritonitis or enteritis, would prevent in the first instance any mistake as to swellings of the scrotum from ruptures or other causes. But when such symptoms occur, and such swelling of the scrotum also exists, then the attention must be directed to ascertain the true character of the tumour.

Operation for Strangulated Inguinal Rupture.—The necessity for an operation having been decided on, the cut in the skin should be commenced as high as the external abdominal ring, and carried down about two-thirds of the length of the tumour. There is great benefit in commencing the incision high up, because it affords readiness in getting at the stricture, which is mostly situated at or near this point. The superficial fascia and cremaster are to be divided as I have already noticed, and the rupture sac exposed It must not be forgotten, that in old ruptures, though not large, the cremaster often has acquired considerable thickness, and that though sometimes, not unfrequently indeed, the several coverings of the sac may be distinctly made out, even as to the precise number of layers, yet very frequently this is not the case, and the depth between the skin and rupture sac varies considerably. The bluish semitransparent appearance of the sac under favourable circumstances having shown that it is exposed, it should be carefully scratched open with a probe sufficiently to admit a director, and as soon as possible the finger, and then slit up cautiously to the ring, so that the contents of the sac may be exposed and examined. The finger is then introduced to find the seat of stricture, which, according to Sir Astley Cooper's opinion, "will be sometimes found at the abdominal ring," which "is the principal point of strangulation in old and large herniæ; but it is more commonly seated at the internal ring, at the place where the spermatic cord first quits the abdomen." (P 29) He also considers that the mouth of the rupture sac sometimes forms the stricture, as he observes,—"The mouth of the hernial sac, when it becomes the seat of stricture, has been thickened on the inner part by the pressure of the tendons of the internal oblique and transverse muscles." (P. 30.) Dupuytren, however, holds "that in the greater number of cases the neck of the rupture sac is the cause of the mischief; * * * and he thinks he can prove that of nine cases of strangulation, eight depend on the constriction exerted by the neck; and he is not sure that even that is the true proportion." (Vol. I.) How the neck of the sac forms the stricture he explains in the following clear and satisfactory manner:—"This change depends upon the situation of the ring. As the rupture increases in size, the neck of the sac puckers and folds by the weight of the rupture, by the tendency of the displaced peritoneum to return upon itself—a disposition proved by the obliteration of the vaginal tunic in children, the form of omental rupture, thin at the ring and bulky at the bottom of the sac. But the principal cause of this circular groove, of this narrowing of the neck, depends on the application of a truss · the compression it effects on the neck of the sac puckers, contracts, and inflames it as well as the cremaster and cellular tissue; whence results a narrowing and a stricture, if not fibrous, at least which affords great resistance. The neck of the sac may even become cartilaginous." The seat of stricture being ascertained, the finger tip or nail must, if possible, without violence, be entered into the mouth of the sac, and the hernia knife carried in flat upon it till its cutting part may be presumed to have reached the stricture, when it is turned on edge, and by a pumping or sawing motion made to divide it, the finger on which the knife rests being gently pushed onwards till there is sufficient room made to allow it to enter the belly; the knife is then to be laid flat and withdrawn.

The division of the stricture is the most important step of the operation, on account of the possibility of injuring the epigastric artery. The stricture should never be divided inwards or outwards: for if it be divided inwards, and the rupture be oblique, the epigastric artery will be either cut through or wounded, as in Prep. No 1,298 of St. Thomas's Collection, and if the cut be made outwards, and the rupture be direct, then the epigastric artery will be cut through, as happened to Sir Astley Cooper, in the case mentioned by himself, in which he had followed the direction, now long since abandoned, of dividing the stricture outwards. I have said before, that, except in very recent cases, or from dissection, I believe it almost impossible to distinguish between direct and oblique rupture, and, therefore, the stricture should only be divided in such way as will ensure, under the natural and usual course of the epigastric artery, its avoidance. With this intent Sir Astley Cooper laid down as a rule to be invariably followed, the division of the stricture directly upwards—that is to say, towards the front plane of the belly, and this practice is now almost universally and wisely adopted In thus cutting upwards the gut, having been examined and the operator decided as to its healthiness, is first to be returned, and afterwards the omentum, if there be any The edges of the wound are then brought together by two or three stitches, with intermediate strips of plaster to support them, but not to prevent the escape of any serum which may be disposed to exude from the sac, and over the whole a pad of lint is applied.

When the stricture, instead of being situated as usual at or near the external ring, is situated either in the inguinal canal (as in Prep No 1,303 of St. Thomas's Collection), or even at the internal ring (which is more rare), then it is necessary in either case to slit up the tendon of the external oblique muscle to divide the stricture, as it is so deeply situated that it cannot be divided with safety, and sometimes cannot be reached at all, without adopting this proceeding.

Should the stricture not be at or near the mouth of the sac, but be formed by a fibrous band stretching from one side to the other of the sac across the bowel, it must be carefully divided upon the finger or director as may be most convenient. A very good example of this is presented in a preparation, contained in the St Thomas's Collection, from a patient of my own, in which the stricture was formed by a fibrous band as thick as a goosequill

Sometimes the back of the rupture sac bursts and the bowel protrudes into the cellular tissue behind, and there forms for itself a false sac This will, perhaps, at first, cause a little confusion, as if the rupture sac be first opened at its lower part it will appear empty; but when it has been slit up towards the mouth, the bowel will be perceived passing through the back of the sac, and from the cavity in which it is then lodged it may be gently withdrawn; or, if this be difficult, either from the narrowness of the rent or from any adhesions having taken place, the back of the sac must be carefully cut through, and the bowel exposed and dealt with as may appear necessary.

Should the surgeon determine on the division of the stricture external to the sac, as advised by Mr. Key and Mr. Luke, he should proceed according to the following directions given by Mr. Key. "In inguinal hernia the incision may be so conducted as to enable the surgeon to divide the stricture either at the internal or at the external ring. The opening in the skin must be made higher than in the ordinary operation on a bubonocele. The incision should begin at the neck of the tumour, or where it seems to quit the abdomen, and should be continued downwards for about an inch and a half. This will lay bare the lower portion of the external oblique tendon where it forms the ring; a small opening should then be made in the tendon, just above the ring, sufficient to admit the end of the director, which will enable the operator to ascertain if the stricture be at the lower or upper opening. The size of the hernia, and the length of time it has existed, will, in some measure, serve to guide him; but he may immediately decide the point by passing the director downwards under the edge of the external ring, and feeling whether it embraces the tumour firmly or not; or, by making pressure on the swelling below, he may feel if the fluid contents of the tumour can be forced upwards above the ring, so as to distend the sac in the inguinal canal. This point being decided, if the stricture be at the lower ring, he has only to pass his director under its margin, and to divide it to a sufficient extent. If the stricture exists higher up at the neck of the sac, where it will be found in the majority of herniæ of this description, the opening in the tendon should be enlarged for the purpose of passing the director under the deeper stricture. The lower margin of the two muscles will be brought into view, with some of the descending fibres of the cremaster. These may be separated by disturbing the cellular membrane with the end of the director, and the instrument may then be introduced under the transversalis muscle till it reaches the stricture. In the subject, the director when introduced in this manner passes before the transversalis fascia; this will diminish what little risk there may be of wounding the peritoneum, and will carry the knife further from epigastric artery, the tenuity, however, of this fascia will, perhaps, often allow the director to pass beneath it. The instrument should be depressed upon the sac, in order to carry its point under the border of the transversalis, which may be divided to the extent required This operation is more difficult than the division of the stricture in femoral hernia; the principal difficulty lies in the accurate separation of the lower edge of the internal oblique muscle, for the easy passage of the director. The stricture, however, is not so firm in inguinal as in femoral hernia, and the introduction of the director under the transversalis tendon will not be difficult, when it is passed up to the neck of the sac before the attempt is made. The steps of the operation will be much the same in those smaller herniæ which are lodged in the inguinal canal. When the stricture is divided, a greater degree of pressure will be required to return the contents of a large inguinal hernia, on account of the distance from the neck of the sac to the bottom of the tumour, and especially when the omentum forms a part of its contents. In small bubonocele, where the protrusion has scarcely reached the external ring, and accompanied as it commonly is with an imperfect descent of the testicle, the same manner of operating may be followed."

II. Femoral Ruptures

Pass through the femoral ring behind Poupart's ligament, or the crural arch, into the sheath of the femoral vessels, and most commonly are found upon the crease that separates the belly from the thigh.

Femoral Ruptures are of two kinds, *Internal* and *External*, so named in reference to their position in respect of the femoral vessels.

(*a*) Internal Femoral Rupture.—This is by far the most common form of the disease, and, at first, is situated within the femoral sheath between the latter and the femoral vein; but afterwards, as it enlarges, it turns upwards on itself to the crease in the groin.

At the inner side of the funnel-like mouth of the femoral sheath which rests against Gimbernat's ligament, between it and the femoral vein there is a space filled with cellular tissue, which forms the

bed through which the absorbent vessels of the thigh pass into the pelvis. This is, according to Astley Cooper, covered by "a thin fascia which descends on the back of the pubes"; and the same is described by Cloquet as "a membranous partition closing the upper part of the crural sheath, and opposing the formation of crural rupture, as well as the entrance of the finger when pushed from above downwards, above the crural arch. This partition forms above the arch a sort of diaphragm, cellulo-fibrous, whitish, thick, and very resistant in some subjects, simply cellular, weak, and readily yielding, in others." He proposes calling it the crural septum," and describes "its upper abdominal surface as concave; its lower, towards the crural canal, convex (p. 73, 74). Mr. Lawrence, however, says that he has not found, on dissection, either the "thin fascia" or the "crural septum"; in which statement I fully agree, believing this to be nothing more than the cellular bed of the absorbent vessels.

Against this cellular tissue, in internal femoral rupture, the peritoneum bulges down and forms the beginning of the rupture sac, which, as it descends behind Poupart's ligament, is continued with the femoral vein and on its inner side into the sheath, which it speedily distends, and continues descending till it reaches the termination of the saphenous vein into the fermoral vein. In thus passing and increasing in size it becomes apparent, bulging forwards through the large oval opening of the fascia lata at the top of the thigh And thus the rupture sac obtains a covering from the sheath, to which Sir Astley Cooper applied the name "fascia propria"; which, however, seems to me a very inappropriate title, inasmuch as it is not a new formation, as the term would seem to imply, but merely a distention of the original sheath. In a recently-produced, or small, femoral rupture, the sac and its covering from the sheath remain by the side of the vein; but as the rupture increases in bulk, instead of descending lower in the sheath, which is prevented by the termination of the saphenous vein, it protrudes inwards the inside of the top of the sheath just below Poupart's ligament, through which the absorbent vessels enter the sheath, giving it the appearance of a sieve, whence it has been called the cribriform fascia, which, being weakened by these holes, yields more readily than the other parts. As it and the sac continue to enlarge, they generally rise up towards the crease of the groin, where the cellular tissue is most loose, and thus a swelling is formed; the bulk of which is above the point at which it had protruded from the inside of the sheath. When the swelling has attained this size it generally overlaps more or less the femoral vein, and sometimes even crosses in front of it and the femoral artery, as in Prep. No. 1,322 of St. Thomas's Collection. Occasionally, upon the surface of the fascia propria, a gland or two are found which may cause a little difficulty in operating on such a case. An instance of this occurred to me, in which there were two glands connected, probably by their vessels, which resembled a chain-shot, and deeply indented the fascia propria and rupture sac. The fascia propria is covered in front by the general connecting cellular tissue, or fascia superficialis, and the skin; but it never has any covering from the fascia lata, as by some surgeons it is said to have.

It is common to speak of the situation of the epigastric artery in reference to the mouth of the rupture sac, or the part where it first begins to thrust inwards the femoral sheath, and to describe it as on the outer side. But under ordinary circumstances, and with its usual origin, the artery has nothing to do with the sac's mouth, being far away and above it. Only when the epigastric arises low down, and from the femoral artery after it has entered the thigh, can it be fairly spoken of as having any relation to the mouth of the sac, and then it is separated from it by the breadth of the femoral vein.

But there is a disposition of the arteries at the groin which has an important relation to femoral rupture. This happens when the epigastric and obturator arteries are given off from a common short trunk, which may arise either from the external iliac within the pelvis, or from the femoral artery in the top of the sheath. This subject has long since attracted the attention of anatomists, but it has been more carefully inquired into by Cloquet, who says that "when there is a common trunk, the separation of the two arteries usually occurs outwards, sometimes above, rarely below, the upper opening of the crural canal (or sheath). In the first case the obturator artery descends downwards and inwards towards the subpubic (or obturator) hole, and is found entirely on the outside of the upper opening of the crural canal, or even without any relation to it." This I have never seen. "In the second case, the obturator artery descends almost vertically behind this opening, and is found nearer Gimbernat's ligament, in proportion as the common trunk is of greater length. Finally, in the third case, the common trunk dives into the crural canal, or rather arises within it, and the two branches it gives off re-enter the abdomen; the obturator artery, more or less tortuous, mounts on the pubes, and bends back upon its upper edge to descend into the hollow of the pelvis towards the subpubic hole, the epigastric artery turns beneath the crural arch, and runs upwards and inwards towards the rectus muscle. * * * Frequently the obturator artery arises on one side by a trunk common to it and the epigastric, and on the other, from the hypogastric or internal iliac artery. It rarely arises directly from the external iliac." Cloquet has also taken the pains to keep a register of the comparative number of subjects in which the obturator arose from the internal iliac, from the external iliac, and from the epigastric arteries. And from examination of two hundred and fifty cases, half of which were men, and the other half women, he obtained the following results:—

From the internal iliac artery on both sides ....in 160 subjects	87 men 73 women
From the epigastric in 56 "	21 men 35 women
From the internal iliac on one, and the epigastric on the other, side, in 28 subjects	15 men 13 women
From the femo[ral] in 6 "	2 men 4 women
Total 250	250

In another calculation, from 500 subjects, he found that the obturator artery arose—

From the internal iliac artery ....in 348 cases	191 men 157 women
From the epigastric or crural artery ...in 152 cases	58 men 94 women
Total 500	500

Whence it appears—First, that the instances of the obturator arising from the internal iliac are the most numerous; that they are to those from the epigastric or crural artery nearly as three to one. Secondly, that the obturator artery appears to arise rather more frequently from the internal iliac in man than in woman, though the excess in the latter is not great. (P. 71—73)

Of the three directions which Cloquet speaks of as being taken by the obturator artery, when it arises either in common with the epigastric or from the femoral artery, I have never seen but that in which the common trunk inclines inwards above Poupart's ligament, and the obturator artery descends from it along the edge of Gimbernat's ligament to the back of the obturator hole; and consequently, if a femoral rupture exist, it must pass around the mouth of the rupture sac close to Poupart's ligament, as in Prep. No. 1,348 of the College Collection; and this is the situation in which, thus arising, the obturator artery is almost invariably found.

My friend Mr. Dixon has, however, met in the dissecting-room with another very remarkable variety—a common trunk from the external iliac giving off three branches, an upper one taking the course of the epigastric artery upwards and inwards, and two below, the hinder and smaller of which descends behind the pubic bone, taking the usual course of the obturator when arising from the epigastric, whilst the front and larger one passes downwards and forwards behind the inner part of the crural arch, and dips down before the pubic bone to the external obturator muscle; so that in this case, did a femoral rupture exist, not only would its neck be surrounded on the inside by the hinder obturator artery, but its front would be crossed by the front obturator.

The College Museum also possesses a very curious prep., No. 1,347, in which, though the epigastric arises from the external iliac, and the obturator from the internal iliac artery, yet the two are connected by an anastomosing branch which runs around the inner edge of the femoral ring. Could this have been like to the case mentioned by Mr. Key, in which, in operating on a femoral rupture, "a small branch given off from the obturator artery crossed the fore part of the neck of the sac, and was cut through in dividing the stricture: the obturator artery itself, which arose from the epigastric, passing into the pelvis behind the neck of the tumour?" (P. 67).

Now, although, by Cloquet's comparison, it appears that the obturator artery is given off from the external iliac three times as frequently as from the epigastric or crural artery, it is very remarkable that, so far at least as I am aware, no instance is recorded in which that vessel has been wounded in dividing the stricture of a femoral rupture, though its frequent situation about the mouth of the sac would seem to make this unavoidable. Sir Astley Cooper indeed says, "that in all the (six) cases, which he himself had dissected, where this variety existed with crural hernia, the obturator passed into the pelvis on the outer side of the neck of the sac, entirely out of the reach of any danger from the knife." He, however, mentions three cases in which the obturator artery ran over the mouth of the sac, and descended into the pelvis on the inner or pubic side. In a College Preparation, and the Prep. No. 1,286 of St. Thomas's Museum, the artery descends on the inner side of the sac's mouth. Three cases are mentioned by Monro *primus*, one by Mr. Allan Burns, one by Scarpa, and another by Breschet, in all of which the obturator artery was on the pubic side of the mouth of the sac; and Mr. Lawrence mentions that "there are two specimens of double femoral hernia in the Museum at St. Bartholomew's Hospital, with the obturator artery arising from the epigastric on each side. The former vessel runs on the outer side of the neck of the sac in one of these four ruptures, and on the inner side in the other three."—(Page 509). Some other and still more satisfactory reason for the escape of the obturator, in the operation for strangulated femoral rupture, must therefore be sought, than that given by Sir Astley Cooper—to wit, the passage of the artery behind the neck of the sac instead of before it, as in the cases just mentioned it was so met with in eleven cases, while Sir Astley's own instances amounted only to six.

The spermatic artery is also spoken of in connection with femoral rupture; [but it] lies away to the inside, and cannot be inju[red in the] operation, as appears to me, without making [a] division of the stricture to an unnecessary and, therefore, unwarrantable extent. An instance, however, of its division, followed by the death of the patient an hour after the operation, which had not been attended with unusual bleeding, occurred to Arnaud; and examination a large quantity of blood was found in the belly. If, however, an oblique inguinal rupture have long existed, the spermatic vessels, before quitting the belly, not the cord afterwa[rds], may be so dragged out of place as to lie close to the inside of the mouth of a crural rupture, as shown in a case described by Cloquet (page 82, pl. vii., f. 4, 5). According to our mode of dividing the stricture directly upwards, these vessels would not be injured; but in the same preparation the epigastric artery has been also displaced by the inguinal rupture; and, running immediately across the neck of the femoral rupture, its division could scarcely be avoided. Probably, when inguinal and femoral rupture exist on the same side, this disposition of the spermatic and epigastric vessels must exist, although it has not been noticed except by Cloquet.

Other swellings about the groin, and in or near the seat of a femoral rupture, may be mistaken for that disease. The neck of the rupture sac may have been closed, probably by the use of a truss,

and its communication cut off from the belly, as in Prep. No. 1,280 of the College Collection; and if, as Cloquet mentions, it contains serum its confusion with an actual rupture is not remarkable. In the museum at St. Thomas's there is, however, a preparation of a serous cyst as big as a pigeon's egg, occupying the place of a femoral rupture, but which has no appearance of having been a rupture sac. Sometimes an absorbent gland, the existence of which among the coverings of femoral rupture is by no means unfrequent, becomes considerably enlarged, and may be mistaken for rupture, as it suffers a slight impulse from coughing. And this will occasionally go on to suppuration, and be attended with nausea, stercoraceous vomiting, hiccough, and costiveness; a case of this kind occurred to Mr. Macilwain, who, considering it a doubtful case, cut into it cautiously, and found suppuration to have begun in the centre of the swelling: the patient did well. (Page 308.)

Psoas abscess may be mistaken for femorla rupture, as it distinctly increases on coughing; but it is not materially altered in size by change of position; and the pain in the back with which the disease has commenced, and which, more or less, constantly accompanies it, will distinguish it from rupture.

On the other hand, femoral ruptures may be mistaken for buboes, and though, probably, there are now "few persons so prejudiced as to decide that a swelling in the groin, if in a young person, is bubo, and, if in an old one, a rupture," and he give ground to Petit's arch observation, that though "he quite agrees with them that it is more common for old people to have ruptures, and young folks buboes, yet that it is very possible that the contrary may happen, and that the point is then not as to the age, but as to the disease itself" (p. 258). Yet such mistakes do occur, and ruptures have been opened to the great dismay and surprise of the medical attendant, and certainly with much less dangerous results, as the cases mentioned by Petit and others prove, than when such swelling has been poulticed for some days, under the notion of encouraging them to suppurate, and their true nature only discovered when the case has been put under the care of some more able and experienced surgeon, and the operation for strangulation, when performed, found to be too late, as in the instances mentioned by Sir Astley Cooper, in which, after poulticing for three days a supposed venereal bubo, the operation was performed, and a mortified gut found.

Serous cysts are sometimes found upon the rupture sac, an instance of which occurred to me some time since. On cutting into it, fluid escaped, and I supposed I had opened the rupture sac and exposed the bowel; but it remained so extremely immoveable that I began to doubt, and further examination showed the sac unopened. I therefore proceeded with the operation; about a teaspoonful of fluid escaped, and the operation was finished under the ordinary circumstances. Mr. Samuel Cooper also cut into several cysts in operating on a case of femoral rupture; and the same fact has been noticed by Sir Charles Bell.

Sir Astley Cooper mentions an example of enlargement of the femoral vein immediately below Poupart's ligament, and projecting through the oval hole in the fascia lata, which dilating when the patient coughed, by the pressure of the bowels upon the iliac vein, had great resemblance to a femoral rupture. At present there is in St. Thomas's Hospital a case of this kind, in which the swelling of the vein just below the crease of the groin has precisely the same form as a small femoral rupture; but it has a bluish tinge from the transparency of the skin, and yields to slight pressure more readily than a rupture.

Sir Astley Cooper observes that a femoral rupture sometimes, "instead of crossing the thigh in the direction of the crural arch, extends downwards along the edge of the crural vein and the *saphena major vein* (p. 1). The tumour does not quit the sheath for the femoral vessels. (He should rather have said, does not protrude it inwards, for under ordinary circumstances it does not leave, but only protrudes, the sheath inwards and upwards.) The appearance of this disease is that of a general swelling of the fascia on the inner side of the femoral vein, but without its producing any circumscribed tumour. The part swells whenever the patient coughs or uses any considerable exertion; but the swelling diminishes, though it does not entirely subside, when he stands at rest. * * * He believes it to be not an unfrequent variety, as he had met with it three times in the dead body, and it existed on both sides in each" (p. 25). Mr. Callaway tells me that one such case was under his care, which had been presumed to be a varix of the femoral vein; but was controlled by the use of a truss. Besides these, however, I know of no other cases, and therefore do not think it so frequent as Sir Astley Cooper would seem to infer.

Internal femoral rupture is sometimes confused with inguinal rupture. It appears to me that this can only depend on ignorance or carelessness. The situation of inguinal rupture, immediately after it has left the inguinal canal, to the inner side of the spine of the pubic bone and the outer column of the ring, and that of femoral to the outer side of the same parts, is always sufficiently apparent to prevent mistake. And, indeed, when inguinal rupture is in the inguinal canal—which is the only period it can have anything like resemblance, as to position, with femoral—it may always be readily distinguished by the crease of the groin remaining distinct, and by the oval form of the swelling, which, like the canal, has an oblique course. Whilst in femoral rupture the crease of the groin is interrupted and, indeed, destroyed by the rounded swelling, which is situated partly in the thigh and partly on the belly, and will not unfrequently permit the fingers to be got in behind it, between itself and the tendon of the oblique muscle, which shows that the protrusion is not above the crural arch.

In rare instances there are more than one femoral rupture, a remarkable instance of which is seen in one of the preparations of the College Collection.

Sometimes femoral and inguinal rupture exist at the same time and on the same side. In the Museum of St. Bartholomew's Hospital there is an example of oblique inguinal and femoral rupture on each side; and Mr. Teale mentions a similar case recently in the Leeds Infirmary.

(*b*) EXTERNAL FEMORAL RUPTURE.—In very rare cases the peritoneum is protruded behind the crural arch into the top of the funnel of the crural sheath on its outer part, between itself and the femoral artery, and thrusts before it the sheath. It appears between the femoral vessels and the upper front spine of the hip-bone, forming a moderately-raised swelling, which, becoming narrower below, ascends obliquely inwards, and terminates with a blunt point in the region of the little trochanter. On the outer side it has the m. rectus and vastus externus, and upon or before it the sartorius muscle and part of the fascia lata. The neck of the sac, which is its widest part, has for its inner wall the iliac fascia, and for its outer wall the iliacus internus and psoas magnus muscles. I cannot very well make out from the description given by Hesselbach, who was the discoverer of this form, whether he thinks the rupture sac fairly enters the outer part of the sheath, or whether it protrudes the iliac fascia nearer to the iliac attachment of Poupart's ligament; but I cannot conceive there is room for it to do other than descend fairly into the top of the sheath and thrust it down.

Femoral rupture is also said to descend in front of the femoral artery and vein, and have the epigastric artery on the inside of its neck. Cases of this kind have been seen by Hesselbach, Cloquet, and two instances by Mr. Stanley. Cloquet also speaks of a femoral rupture passing through a hole behind the vessels, and separated from them by the deep layer of the fascia lata.

Varieties in femoral rupture, when in its usual situation, sometimes occur. Sir Astley Cooper mentions three varieties: first, that in which "the fascia usually covering the hernial sac has given way, so as to allow a portion of the tumour to pass before it, thus dividing the tumour into two parts, with a sort of hour-glass contraction between them." (P. 25.) Second, "when the sheath for the crural vessels." in which the hernia is formed in part within its sheath, and also in the common way." (P. 25.)

I have had three cases which do not seem to resemble either of the varieties described: in two of these the rupture sac had probably given way on the outer side, and there remained only a covering of skin; the third (the preparation of which is in the St. Thomas's Collection) seems to be a very similar case, only the rupture sac was not so lengthy outwards as in the first case. In my third case the sac had probably given way on the inner side.

A Course of Lectures on Practical Midwifery.

By EDWARD RIGBY, M.D.,

Fellow of the Royal College of Physicians, Senior Physician to the General Lying-in Hospital, Lecturer on Midwifery at St Bartholomew's Hospital, Examiner on Midwifery to the University of London, &c.

Delivered last session at St. Bartholomew's Hospital, and revised by the Professor for the "Medical Times."

In my last lecture, gentlemen, I described to you the differences between the male and female pelves, and explained the effects which those differences must produce on the process of labour. I also gave you an historical summary of the progress which has been made in understanding the mechanism of parturition; and you will recollect I told you that the true account of the child's position was given by two writers at the same time, and apparently without the least knowledge or connection with each other. Saxtorph and Solayres de Renhac both described the most common position of the child as being that in which the sagittal suture corresponds to the right oblique diameter of the pelvis, the posterior fontanelle being directed forwards and to the left.

I now am going to describe the different positions of the head; and first of all I think I had better mention them to you as they have been described in the various works of midwifery; I shall afterwards describe the simple manner in which they really occur in nature.

The German writers on midwifery have described four positions of the head; the French and English authors, six. Two of these have been very properly omitted by the German school of midwifery as not occurring in nature.

It is, gentlemen, allowed on all hands that the position of the child in which the head occupies the right oblique diameter of the pelvis, the posterior fontanelle being turned forwards and to the left, is the most common. This has, therefore, been described by all authors as *the first position of the head*.

In *the second position* of the head the sagittal suture occupies the left oblique diameter, the posterior fontanelle being turned forwards and to the right.

In *the third position* of the German school the reverse of the first takes place; that is to say, the sagittal suture still occupies the right oblique diameter, but the anterior fontanelle is turned forwards and to the left, instead of the posterior.

The *fourth position* is the reverse of the *second*; the sagittal suture still occupying the left oblique diameter, the anterior fontanelle being turned forwards and to the right.

These positions, as established by the German school, are much more simple and correct than the six positions established by Baudelocque, and followed by the French and English schools. Baudelocque described four positions, such as I have just mentioned to you, and added two others: one, his third position of the head, was where the sagittal suture corresponded with the antero-posterior diameter of the pelvis, the posterior fontanelle being directed forwards towards the symphysis pubis; the other, his sixth position, was the reverse of this, the anterior fontanelle being directed to the symphysis pubis. These two positions the German teachers have very properly rejected, as they are purely hypothetical, and do not exist in nature. The correct presentation of the child's head (the *situs capitis rectus atque aequus*) was formerly sup-

posed to be with its long axis corresponding to the transverse diameter of the pelvis; and the old writers on midwifery all state that it is necessary for the head to make a turn while entering the cavity of the pelvis, so that the face shall get into the hollow of the sacrum (its long diameter being parallel to the antero-posterior one of the pelvis), when the face, sliding down the inclined plane offered to it by the sacrum, sacro-ischiatic ligaments, and coccyx, is forced to pass with the occiput forwards under the pubic arch.

I have now, gentlemen, enumerated the positions of the head as they are described by authors of the three great schools. I shall next proceed to explain them to you as they really occur in nature. To discover the position of the child's head, gentlemen, is one of the most difficult points in practical midwifery, and this has, perhaps, been the cause of so many complicated presentations being described, authors have found it much easier to calculate the position in which the head *ought*, in their opinion, to pass, than to observe what really takes place in nature. To form an accurate diagnosis respecting the presentation requires a considerable degree of what has not inaptly been called the *tactus eruditus*, which can only be acquired by lengthened experience added to careful observation.

At the commencement of labour the os uteri is found high up in the hollow of the sacrum, directed backwards, as I believe I have before told you; it, therefore, as Baudelocque asserted, the vertex of the head presents, the sagittal suture should be the lowest part of the cranium, and the one which the finger would first touch on in making an examination. This is not the case, however, as Smellie first observed. When at the commencement of labour the os uteri is enough dilated to admit the finger, it is felt in this presentation to be crossed by the sagittal suture, which divides it unequally; the vertex, therefore, gentlemen, *never presents*, the sagittal suture, crossing the os uteri, which, remember, I have just told you is directed to the hollow of the sacrum, is also turned in the same direction. The perpendicular diameter of the head is therefore parallel to the axis of the brim of the pelvis, which corresponds with a line drawn from the centre of the brim of the pelvis through the umbilicus of the mother. The right side of the head, or the right parietal protuberance, is therefore the part first touched by the finger in the most common position of the head, being the part which is lowest or deepest in the pelvis at the commencement of labour. We may therefore say, that *in the first position the direction of the head at the beginning of labour is with the sagittal suture crossing the os uteri, and the right parietal protuberance placed lowest in the pelvis*. So far from the posterior fontanelle being invariably the lowest, the anterior is often felt quite as low, and sometimes lower than the posterior, without in any way rendering the labour less favourable.

As the head enters the cavity of the pelvis, it does not turn, as has been stated by writers on midwifery, into the hollow of the sacrum, with its long diameter in the antero-posterior diameter of the pelvis; but it still retains the oblique position and even when fairly in the cavity of the pelvis it remains placed obliquely, the sagittal suture corresponding with the right oblique diameter of the pelvis, the posterior fontanelle turned to the left foramen ovale. Neither does the head pass under the pubic arch with the occiput forwards, as it has been stated to do, but it is the posterior and superior quarter of the right parietal bone which first enters the vagina, and which first passes beneath the pubic arch. It is the right branch of the lambdoidal suture which at this moment will be felt parallel to the left descending ramus of the os pubis. After all, the process is nothing more than this—the head enters the pelvis *obliquely*, it passes through *obliquely*, and it comes out *obliquely*.

I will now point out to you two or three circumstances occurring during labour which prove the correctness of this view of the manner in which the child's head passes through the pelvis. If the head be pressing firmly on the os uteri at the commencement of labour—if there be but little liquor amnii present, or if the membranes have been ruptured early and the liquor amnii has escaped—a puffy œdematous swelling forms on that part of the scalp which corresponds to the os uteri; if the head should be expelled suddenly, the swelling will be found situated upon the sagittal suture. This swelling, you will remember, I have before described to you; there is no term for it in English, so it has been called the caput succedaneum, and you know that it is caused by the pressure at first of the os uteri, and afterwards of the vagina obstructing the return of blood through the veins of the scalp. This swelling, therefore, must be formed on the part which is encircled by the os, and therefore in the first part of labour it is found on each side of the sagittal suture. As the os uteri dilates, and the head gradually descends and alters its position, this swelling disappears in part and now forms over the posterior and superior quarter of the right parietal bone, or that portion which first enters the vagina. Now, gentlemen, if the vertex presented, where would this swelling be situated? Over the occipital fontanelle; but this is never the case. If the head presented with the sagittal suture in a line with the antero-posterior diameter of the pelvis, it would also be in a line with os externum. This is *not* the case, for in passing through the os externum the sagittal suture crosses the left labium obliquely at an acute angle. When the head is expelled the face does *not* turn directly to the right thigh of the mother, as it ought to do if the shoulders were passing through the pelvis with their long axis in its antero-posterior diameter, but it turns obliquely backwards, with the face looking towards the posterior part of the mother's right thigh, as, of course, the shoulders take the other oblique diameter.

I therefore repeat to you, gentlemen, that the head enters the brim of the pelvis *obliquely*, passes through the cavity of the pelvis *obliquely*, and makes its exit from the inferior aperture of the pelvis *obliquely*.

The *second position* is exactly the opposite of the first, the sagittal suture being parallel to the left oblique diameter of the pelvis, and the posterior fontanelle corresponding to the right foramen ovale. This position has been stated by some to occur almost as frequently as the first, and Professor Von Siebold, of Berlin, remarked, that in nearly all the labours which occurred during two months at the lying-in hospital to which he was attached, the head presented in this position. In this position the head is stated by the works on midwifery to pass through the pelvis as in the former case, that is, the head on entering the cavity of the pelvis turns with the sagittal suture into the antero-posterior diameter of the pelvis, the face into the hollow of the sacrum, and when the head passes through the inferior aperture of the pelvis it comes with the occiput foremost under the pubic arch.

In the third position, where the long diameter of the head is in the right oblique diameter of the pelvis, the anterior fontanelle turned forwards and to the left, the occipital fontanelle to the right sacro-iliac synchondrosis, it is stated to enter the pelvic cavity much in the same way as in the first and second positions, viz., it gradually turns with the sagittal suture into the antero-posterior diameter, the occiput now occupying the hollow of the sacrum, as the face did in the two other positions, the forehead directed forwards towards the symphysis pubis, but, being too broad and too flat to pass under the pubic arch, it is forced upwards behind the symphysis pubis by the continued action of the uterus, while the occiput, in the hollow of the sacrum, descends and passes foremost over the perineum, which it distends enormously.

Now all this, gentlemen, by no means agrees with what we find in nature, as Professor Naegele very truly said in his lectures sixteen or seventeen years ago, "One author has imagined it, and the others have copied it from him. According to them the third position of the vertex should be of by far less frequent occurrence than the second. I have" (says he, MS lectures) "observed as many labours as any accoucheur in Germany, and from my observations, which I have made for many years with the greatest possible attention and care, the third position after the first is by far the most frequent in occurrence of all the head presentations. On the other hand, the second position of the head, which has been supposed to be so frequent, occurs as an *original* presentation very rarely."

"The manner in which the head," says Professor Naegele, "when in the third-vertex position, is directed during labour and moves through the pelvic cavity, is according to my observations as follows.—At the beginning of the second period of labour, and in those who have borne children even earlier, the great or anterior fontanelle is felt directed towards the left foramen ovale, and the smaller or posterior one to the right sacro-iliac synchondrosis nearly at an equal height—sometimes one, sometimes the other, being reached with greater facility. As the right parietal eminence in the first position of the head is the most depending part, so in this case it is the left. When the point of the finger is brought in contact with the head in the direction of the central line of the pelvic cavity, it touches the protuberance of this bone. As the head enters and passes through the superior aperture of the pelvis, the anterior fontanelle corresponds always to the left foramen ovale, as the posterior one does in the first position; and as soon as the head has engaged in the cavity of the pelvis, the posterior or great fontanelle turns towards the ascending ramus of the left os ischium, and both can be felt at an equal height as to each other.

"As soon as the head experiences the resistance which the inferior part of the pelvic cavity opposes to it,—or in other words, the oblique surface which is formed by the lower end of the sacrum, the os coccyx, the ischiatic ligaments, &c., by which it is compelled to move from its position backwards into a direction forwards,—it turns by degrees with its great diameter into the left oblique diameter of the pelvic cavity, viz., the posterior fontanelle is directed to the right foramen ovale; and, as the head approaches nearer to the inferior aperture, it it is the posterior and superior quarter of the left parietal bone which is felt in the pelvic cavity opposite to the pubic arch, so that, when the finger is introduced under and almost perpendicular to the symphysis pubis, it touches nearly the middle of the posterior and superior quarter of the left parietal bone. This is precisely the part which, as the head advances further, first distends the labia, and with which the head first enters the external passage, it is also the spot on which the swelling of the integuments appears. As in the case of the first position of the head the posterior fontanelle is usually directed to the left when the head passes the external passages, so in this case it is mostly directed to the right."

"In primiparæ, gentlemen, this change takes place slowly, and requires many pains before it is completed. When the pain begins, the posterior fontanelle, which had previously been backwards and to the right, comes forwards and is more within reach, the anterior fontanelle, which had previously been forwards and to the left, at the same time retreating, so that for a moment the head will lie in the transverse diameter of the pelvis. As the pains recur this slight twist is repeated, so that at length and by degrees the head passes not only into the transverse diameter of the pelvis from the right oblique, but from the transverse into the left oblique. The third presentation of the German school is, therefore, converted into the second, in which position the child is born. In multiparæ this change is frequently effected during a single pain.

"In the former part of my practice," says Professor Naegele, "not knowing that the head made this turn, I always concluded that my examinations during the early part of labour had been incorrect. I was very uneasy that I did not find it all exactly as the books described, and I attributed my want of success in ascertaining the position to my own awkwardness. At length, in a private case in which I was much interested, I again felt what I thought was the anterior fontanelle towards the left foramen ovale, and, circumstances occurring which rendered it necessary to apply the forceps and terminate the labour, I found that the head had been actually in the position which I imagined I had felt. Since this time

I have in many cases sat by the bedside with the finger on the head during the whole labour, and I have thus arrived at the truth."

You will recollect, I said that we are told in books on midwifery, that, as in their third presentation the head descends through the cavity of the pelvis, the forehead turns directly forwards until the sagittal suture corresponds to the antero-posterior diameter of the pelvis, the occiput being in the hollow of the sacrum; but that, as the forehead is too broad and flat to pass under the arch of the pubes, it is by degrees forced, by the continued action of the pains, up behind the symphysis pubis, the occiput descending and pressing against the perineum, which it must distend enormously; the forehead is said also to remain behind the pubic symphysis until the occiput is born. Whether such a thing be possible, gentlemen, I leave for you to consider.

These blunders have been perpetuated, gentlemen, from one generation to another; one author has served as a copy for all the rest, and students naturally find, when attending cases of midwifery, what they are told to expect, or, if they do not find what they expect, they naturally attribute their not finding what they are told must be there to their own want of skill.

The very circumstance of the head passing from the third into the second position is quite sufficient to puzzle and mislead. You feel sure you have felt the head, with the anterior fontanelle forwards and to the left at the beginning of labour; and yet when the child is born the occiput is distinctly forwards and to the left; you therefore conclude that your first examination was wrong.

Moreover, it is exceedingly difficult to distinguish always correctly between the two fontanelles, it seems easy enough when you look at them, the one is large and quadrangular, the other is small and triangular, but when the head is much compressed and the bones beginning to overlap, the fontanelles become greatly altered both in form and size, and if from the distance of the head the finger can only just reach it, it becomes very difficult to decide. In such cases if you feel a suture running backwards this must be the coronal suture, and therefore it is the anterior fontanelle; but if no suture is felt running backwards, you may be pretty sure that it is the posterior fontanelle.

The fourth position of the head of the German school was said by authors to follow the course of the third, which I have just described to you, the occiput being made to sweep down and distend the perineum, as was said to occur in the third position. You know I told you at the commencement of the lecture, that in the fourth position it corresponds to the left instead of the right oblique diameter, the anterior fontanelle being opposite to the right foramen ovale, and the posterior fontanelle to the left sacro-iliac synchondrosis. For the child to be born in this position, you know the same difficulties would present themselves as are stated to do in the third position, and the perineum must be just as much distended by the occiput as in it.

"Out of a hundred labours where the head presented," says Prof. Naegele, "which I carefully observed from the very first commencement of the pains till their termination, the third position of the vertex occurred twenty-nine times. Of thirty-six labours which occurred at the infirmary of this place from the beginning of 1821 till the February of the same year, I counted twenty-two with the vertex in the first position, eleven with it in the third; two presentations of the nates, and one of the face. According, however, to the observations I have hitherto made, the proportion of the third vertex position to the first, with respect to the frequency of their occurrence, is as about one to two-and-a-half. During the time that I saw ninety-six cases of the third-vertex position the fourth occurred only twice; and of more than 1,200 cases, which I carefully observed and noted with particular accuracy, I did not find a single instance of the head being originally in the second position. From the observations that I have made," the Professor continues, "I am thoroughly convinced that in cases of the third and fourth positions of the head or vertex, in the more advanced state of labour, the occiput is not usually turned into the hollow of the sacrum; but that in cases of the third position of the vertex, when the labour has advanced considerably, the posterior fontanelle is turned from the vicinity of the right sacro-iliac synchondrosis to the right foramen ovale; and in the fourth position from the left sacro-iliac synchondrosis to the left foramen ovale, and in this manner it clears the external passages; that this change of the third position into the second, and of the fourth into the first, requires no peculiarly favourable circumstances, and that these species of labours can be completed under the usual proportions of the active and passive momenta which relate to the mechanism of childbirth, by the natural means in the same time, with the same expense of strength without greater difficulty &c., than that species of labour where the head takes the first and most common position."

There are, then, gentlemen, only two positions in which the cranium presents in reality, each of them is oblique; in one the right side of the head is foremost, or lowest, in the pelvis; in the other, the left side. The former of these, from its greater frequency, is called the first position of the cranium, the latter we ought to call the second position of the cranium. In England and France these presentations have been called vertex presentations; in Germany, *hinterhaupt*, or *hinderhead*, presentations. Neither expression is strictly correct, as neither the vertex nor the occiput presents, but the posterior and superior quarter of the parietal bone of the corresponding side. It is a curious fact, that in some of the works on midwifery, positions of the parietal bones have been described and commented on as being particularly dangerous and difficult cases. These presentations, gentlemen, ought in strictness to be called parietal, as, if this were the case, the name would indicate the presentation, instead of deceiving as it now does.

I now come to speak to you of the presentations of the face; but as the hour is nearly expired I shall not be able to enter fully on these in the present lecture, so I shall content myself with merely giving you a general view of them at present, and explain them more fully at our next meeting.

Well, then, gentlemen, the face is described by German writers as presenting in four positions analogous to those of the head; and by French authors six positions are said to occur, the two additional ones having been added by Baudelocque, to correspond with his two additional positions of the head. In the first position of the face, according to the German school, the chin corresponds to the left acetabulum, the forehead corresponding to the right sacro-iliac synchondrosis. In the second position the chin is opposite to the right acetabulum, and the forehead to the left sacro-iliac synchondrosis. The third and fourth positions are thus reversed, as before described of the head; and in Baudelocque's additional two, the face is said to occupy the antero-posterior diameter of the pelvis. I shall at my next lecture, gentlemen, resume this subject.

We understand that Dr. Sandys, of Birmingham, has removed to Daventry, to succeed to the practice of the late Dr. Lee of that place, whose death was noticed in our columns some weeks back. From what we know of Dr. Sandys, we feel assured that he will prove a valuable acquisition to the town of Daventry and its neighbourhood.

The Burgomaster of Liege has published the following decree, bearing date the 1st of August.—"The burgomaster, having been informed that the druggists and other shopkeepers are in the habit of selling an arsenical paper to the public for the purpose of killing flies, and believing that this preparation may give rise to fatal accidents, as well as facilitate intentional poisoning, by the advice of the medical commission, and in virtue of Article 15 of the law of March 12, 1818, informs all druggists and others that the sale of such paper cannot take place without a special permission obtained from a local authority, and that those who do not obey this order will be prosecuted according to Article 22 of above-mentioned law."

A Course of Lectures on Diseases of the Skin.

By JAMES STARTIN, Esq., Surgeon to the London Cutaneous Institution.

LECTURE XXIII.

URTICARIA.

According to Willan and others.

		Chronica.

GENTLEMEN,—Our subject for to-day (*Urticaria*), placed by Willan amongst the Rashes (the exanthemata, as he entitled them), has been long known to medical writers and to non-professional persons as the Nettle Rash.

By many authors urticaria has been regarded as an eruptive fever, probably from the above-mentioned classification of it with measles and scarlet fever, but Willan had no intention to promulgate such an error, as he was guided only by the external marks of diseases in his arrangement; otherwise, scabies might be regarded as partaking of the nature of smallpox, because the two maladies are in juxtaposition in the same author's order of pustules—an occurrence on which I have heretofore expressed an opinion I think it unnecessary now to repeat, for I trust it will be obvious, not only from the recapitulation you heard last week, but also from all my former remarks, that identity of nature and practical utility have alone furnished foundations for any attempt at classification you may have perceived in these lectures; all other arrangements I have long since been convinced lead to no certain practical result.

Some years ago I had nearly completed a manual on skin diseases, with the divisions of the subject founded on the real or supposed situations of the various affections in the anatomical structure of the skin; an accident deprived me of my labours, and I am now more than ever convinced that they were not calculated to advance either the understanding or the treatment and cure of these multiform disorders. Since that time, however, the same views have actuated others, and the result is before the public, to whose better judgment I leave the merits or demerits of the undertaking, and return to the subject claiming for the moment my undivided consideration.

The nettle-rash, as you all know, has obtained its popular appellation from the close and complete resemblance it bears to the effects of urtication or stinging with nettles on the human skin. I may observe, however, that this stinging must be carried to an extraordinary degree of severity to produce such examples as those you witness on some of the models, which, however, do not illustrate the most common forms of the complaint. In addition to this identity of appearance, a similarity of sensation is an accompaniment of urticaria, which may be thus defined —A non-contagious eruptive inflammation on the surface of the body, consisting of flattened, slightly prominent, livid, or light red patches, palest in their centres, of variable size, from that of a pea to that of the palm of the hand; appearing insulated or in groups on an otherwise smooth and healthy skin, and being for the most part of an evanescent or fugitive nature, though sometimes becoming chronic, occurring in paroxysms, and often attended by constitutional or gastric disturbance, with pain, itching, and tingling of the parts affected, like the stinging of nettles, the visible effects of which on the skin are very exactly represented by the disease. This affection, observed and described in medical works since the days of Hippocrates, may attack at any period of life; nor do the rich appear to be more exempt from it than the poor; indeed the luxu-

rious habits of the former, added to a certain irritable state of the constitution, particularly amongst individuals of the gentler sex, would appear to be predisposing causes:—still I think I have observed that the disease assumes a more severe form in males than females. The spring, summer, and autumnal seasons seem most favourable to its appearance; and it is commonly produced in its simple and acute forms by eating certain articles of food which, in habits predisposed to this complaint, very constantly excite the eruption. Several substances have a peculiar influence in this respect. muscles and other shellfish, mushrooms, rancid oils or butter, honey, balsam of copaiba, &c.; but their effect is very constantly to be attributed to the idiosyncrasy of the individual, rather than to the poisonous nature of the aliment, as others partaking of the selfsame article have experienced no such deleterious effects. It is also remarkable that external irritation of the skin will produce urticaria in these predisposed individuals, so that we find it complicated with other cutaneous diseases with which such parties may happen to be afflicted: thus, I believe, I have seen every cutaneous disease attended with much pruritus as a symptom, occasionally give rise to urticaria; whilst frictions, the stings of ants or mosquitos, the hairs of dolichos pruriens (cowhage), and other such like agents, have the same effect. I have often been able, *a priori*, to distinguish those skins which would be thus influenced; they are generally blonds, and with much apparent vascularity in the capillaries, which terminate visibly on the surface in minute arboriform ramifications, whilst the integument, when pinched up, appears rather thickened, and to possess less than its usual elasticity. It is not uncommon in these instances to witness the production of urticaria from the slightest friction, or from the pressure of the clothes, the complaint manifesting itself in stripes or bands of various figures, rather than in more or less circular patches; on the disappearance of these marks, a stain resembling a slight bruise is not unfrequently observable on the skin.

Willan divided urticaria into six species, which he named *U. febrilis*, *U. evanida*, *U. perstans*, *U. conferta*, *U. subcutanea*, and *U. tuberosa*. By the chart, to which I have had occasion to refer so frequently, you will perceive the arrangement under which I propose bringing this malady to your notice: which is an endeavour to render the subject at once [illegible] simple and precise; thus I have divided the affection into two species, two divisions, and four forms or varieties, which I intend, from the mere mention of their names, should describe the nature, form, and extent of the disease. The species are *U. simplex* and *U. tuberosa*; the divisions, *localis* and *generalis*; and the forms, *sparsa*, *conferta*, *acuta*, and *chronica*.

Urticaria simplex appears in irregular patches of a more or less circular figure, either after a slight febrile attack, or more commonly from the ingestion of some particular kind of food or medicine, which occasions the appearance of nettle-rash in certain idiosyncrasies. The eruption is first manifested by a red patch or efflorescence, in the midst of which the slightly-raised wheal becomes apparent, and vanishes or removes its situation after a short period, which is rarely prolonged beyond an hour or two in the acute form of the affection. Considerable tingling and itching accompany this rash, which is apt to recur towards the evening and during the night, when the frictions to which the patients subject the parts give rise to a degree of tumefaction and hardness which for the time produce much disfigurement and enlargement of that portion of the body or limb affected. In the face this is most remarkably apparent, the eyelids and features being sometimes scarcely distinguishable. This eruption appears to relieve or carry off the internal disorder, which, with the rash, commonly disappears in a week or ten days, leaving little or no trace of their existence: unless the malady assume the chronic form, when its duration may be for months or years, constituting *one of the most obstinate affections of the skin.*

In the model of the hand from *Sarah Ager*, this was the case, the complaint having existed two years. I have no model of urticaria simplex in its acute form, from the circumstance of their not being very readily obtainable, which arises, in the first place, from the uncertain period of the day at which the disease may be at its height, so that the modeller may be at hand; and in the next, from the evanescent nature of the eruption, which in several instances has taken its departure whilst a cast was being taken—the mere contact of the wet plaster being sufficient to chase away every morbid appearance.

Of the second species, *urticaria tuberosa*, there is a very fine example from the arm of Benjamin Mardell, whose case I shall presently relate. In this instance, as in many others of the chronic forms of the disease, I have traced irregular action of the heart, manifested not only by palpitation, but by fits of syncope. I have not, however, detected abnormal sounds by the ear or stethoscope, and, therefore, am not prepared to say whether, like the nettle-rash, the cardiac affection may not be symptomatic of some gastric derangement. There is very little difference in the first appearance of this species of urticaria and that of the simpler kinds; several wheals, however, usually become confluent, so as to create the immense blotches you see on the model, which are stiff and painful, and last for an hour or two, the paroxysm generally recurring in the evening; and as the disease is influenced by remedies, the size of the wheals diminishes, marking with much precision the progress of the cure.

I have been unable very often to find a cause for these chronic examples of urticaria, beyond [illegible] derangement of the circulation before alluded to. No doubt the complaint is aggravated by unwholesome food and repletion of any kind, as also by the abuse of fermented liquors; but I do not think these can be deemed true causes of the disease, otherwise it would be much more common than is the case. My observations, however, agree with those of Willan, that often the indulgence in some article of food, as gruel, sherry, or raisin wine, &c., may produce a paroxysm of urticaria, and continue the malady in its chronic stages. With regard to the *urticaria perstans* of Willan, I shall consider this disease when speaking of *erythema tuberculatum*, with which it is identical; and *U. subcutanea* has been already described under the genus Prurigo—to which it either belongs or is a concomitant. I have already hinted that these demonstrations of urticaria are very common in diseases of the skin attended with much irritation; and in none more frequently than in scabies. I do not think it can be necessary that I should detain you longer with the description of this characteristic malady, to enable you to form a correct diagnosis; I shall therefore proceed to the treatment I have found most effectual, and the recital of a case or two by way of illustration.

When urticaria, in any of its forms or stages, can be traced to the ingestion of any substance, the removal of the offending body by emetics and purgatives is the evident indication; on the other hand, when it is symptomatic of visceral disorders of any kind, these must claim our attention; and lastly, when the disease may be regarded as idiopathic, and no cause can be assigned for its appearance, its cure is to be attempted upon the principle I have recommended where the derangement of the cutaneous circulation has been productive of other maladies of the skin; for this end my experience has pointed to three remedies which have usually proved efficacious—these are, bleeding when the pulse affords no counter indication; colchicum combined with magnesian aperients and iodide of potassium. In a few rare instances where the malady has lingered and tormented the patient *for years*, I have had recourse to large doses of liquor potassæ, and small ones of Fowler's solution, with good effect; but this remedy is only admissible in these cases, and would appear to aggravate the acute manifestations of the disorder. I think it useless here to recapitulate the constitutional treatment required in the event of any disorder of the system, as on former occasions I have endeavoured to make you acquainted with my views; and, therefore, I will at once read a case from the register of *Urticaria simplex generalis sparsa.*

Benjamin Broad, aged thirty-five, residing in York-road, Lambeth, was admitted on the 1st of October last (No. 6,260); having suffered for two days from a scattered eruption of large wheals of a circular figure which were spread over the whole body, excepting the scalp, palms of the hands, and soles of the feet. The spots of this nettle-rash were mostly circular and about the size of a silver penny, appearing for an hour or two after dinner and leaving for the rest of the day, with the exception of a spot or two, which might arise from scratching the part, or from the friction of the dress; there was a degree of "stiffness felt all over the body, and soreness attended with tingling and itching." He could give no cause for the eruption, but stated that he had been harassed a good deal with his work, and had much exerted himself, which he thought had made him "poorly for a day or two before he broke out," since which time he had "inwardly felt better." His tongue was white, skin hot and dry, and bowels not in a good state; so that he was advised to use the vapour bath forthwith, and to take every four hours about ten drops of the wine of colchicum, with a little carbonate and sulphate of magnesia, and to visit me again in three or four days. At the end of this time he presented himself relieved, and was told to continue the same remedies twice a day only, and the vapour bath once or twice a week. At the end of a second four days, I saw him again; all the pain and stiffness appeared to have subsided, and the nettle-rash now showed itself rarely, and in a much diminished form; I therefore advised him to take four or five grains of the iodide of potassium twice a day, and to dust the spots as they appeared with hair-powder, with a view of diminishing any friction to which they might be exposed. On the 17th of October, rather more than a fortnight from admission, he was quite well, and has had no relapse. This was a very severe case in the first instance, and therefore I am inclined to believe that the remedies used were beneficial.

The next example I shall adduce is one of a chronic form of the same disease, *Urticaria simplex chronica*, the *U. perstans* of Willan. This patient, whose malady is represented by the model (No. 5,668), was named Sarah Ager, aged forty, of Plastow, in Essex. She was admitted on the 9th of July last, having suffered one year and ten months from the chronic nettle-rash. By her statement the malady commenced without any assignable cause. Save that she had been weak and indisposed for some time, and had lost flesh, her appearance corroborated the latter statement, for she was a very small woman, as you may judge from the model of her hand, and presented the appearance of having many years passed the age she gave herself. The whole of her body was covered with this rash, except the head and face. It appeared, as she stated, precisely like a bug or gnat bite, and at first was mistaken for these injuries; and the spots remained itching, painful, and swollen, for about three days, when they disappeared, leaving a slight mark on the skin like a bruise, and another crop of the eruption made its appearance. The uneasiness and irritation were greatest at night, and appeared to have been aggravated by all the means she had used. After a careful examination into this case, I could detect no proximate cause for the eruption; the pulse was slow (not more than sixty) and slightly intermittent; there was dyspepsia and leucorrhœa (yet not in a degree to lead you to believe in the existence of uterine disease, which by Dr. Gooch and others has been cited as a cause of this form of urticaria); the bowels and catamenia were natural enough. Under these circumstances the first remedies used were of a general nature, directed for the removal of the symptoms I have detailed; a tepid bath every third day being ordered to equalize the cutaneous circulation, which I regarded as the system most implicated in the production of the rash. She continued these means for a month; and, as she lived some distance from town, her visits to me were at intervals of a fortnight or three weeks. There was little change in the urticaria for the first and second visits, though a slight improvement was visible in the general health. She now took, by my direction, four grains of the iodide of potassium twice a day, for a month, at the

end of which period the eruptions had diminished in number, duration, and size. The model was taken about this time, so that you see its position when the cure was half accomplished. On this patient's first application the wheals were larger and, perhaps, twice as numerous—the resemblance to a bite, or sting, being always very complete, *the central wound of course excepted*. At the end of the third month the disease seemed stationary, and the iodine had begun to manifest its peculiar action on the system, a coppery taste in the mouth and a spongy state of the gums being evident, as though mercury had been administered; and this, notwithstanding aromatics, opiates, and bitters had latterly been given in combination with the remedy. This was in October, three months from her admission, when I prescribed four drops of Fowler's solution with thirty drops of the liquor of potash, twice a day in a weak infusion of senna or rhubarb, and made her stay in town to use the vapour-bath. A very evident change for the better was soon manifested, so that at the end of another month, November 22nd, she had been free from her long-standing disease for nearly three weeks, and I pronounced her *cured*.

I omitted to mention that this patient used warm creosote-water as a lotion, with some apparent advantage, as regards assuaging the irritation of the eruption, which, at bedtime, often prevented her repose.

The case of *urticaria tuberosa* exemplified by the model, to which I point, is that of Be[illegible] Mar[illegible], aged 40, who was admitted on the 10th of last October, 1845 (No. 6,311), after having suffered six months from the eruption you there see represented.

By the account of this patient, the urticaria appeared, with much regularity, about eight o'clock each evening, and took its departure in the course of the night, leaving little or no marks in the morning; it was accompanied with much pain, languor, and lassitude, and a degree of tumefaction of the affected parts, which impeded motion, or when on the face or genitals, as was often the case, occasioned much distortion and disfigurement. With the exception of the palms of the hands and soles of the feet, every part of the surface was visited with this eruption; yet very little of it was to be seen during the day, a spot here and there only. Consequently the modeller waited upon him at his residence, 26, Cure-street, Bethnal-green, and there took the cast before you, which perfectly represents the disease. The account Mardell gave me of the origin of this most rash was not satisfactory, as regards the mention of a proximate cause; he had lived irregularly, like most working men, and his health was not good, but these can only be considered predisposing circumstances. In his pulse, however, which was slow and irregular, I think an indication leading to the true origin of the complaint might be traced; on putting my ear to his chest, I found I could hear the heart much beyond the region it ought to occupy, and much of the regular *tick tack*, if I may so term it, in its beat was absent—a confused murmur now and then supplying its place. I, therefore, surmised there was enlargement and dilatation of the organ, and, consequently, prescribed a chalybeate joined to an alkali and vegetable bitter, and the tepid bath, with a warm lotion containing diluted nitric acid and creosote in slender proportions, to moderate the itching of the surface, whilst, with the view of relieving the immediate symptoms, venesection was performed to ℥viij.

By the end of the first week this treatment had caused some amelioration, so that the same remedies (excepting the bleeding, of course) were continued till the 24th of October, when the spots were reduced from the size you see them to that of an ordinary gnat bite. The sulphur vapour bath was now added to the treatment, to be used twice a week, whilst a dose or two of calomel and the ordinary black draught were superadded to the internal medicines, the continued improvement of the eruption and general health was progressive under this system, and no material change was made, till on the 7th of November he presented himself *cured*, having been about two months under treatment. I should mention that the diet was carefully regulated, and all excesses and stimulants forbidden. This patient again applied about a fortnight ago with a slight relapse, as he thinks, from a return to drinking malt liquor.

A repetition of the medicines and sulphur vapour baths were ordered him, and I may probably see him next week again free from his urticaria, I will then once more take an opportunity of examining the state of his heart.

The subject for next week, gentlemen, will be *Roseola*.

ORIGINAL CONTRIBUTIONS.

PRACTICAL REMARKS ON THE EMPLOYMENT OF IODINE, AND ON THE COMPARATIVE VALUE OF THE LOCAL AND GENERAL TREATMENT BY IODURETTED PREPARATIONS.

By DR. LUGOL.

Translated for the MEDICAL TIMES by ALFRED MARKWICK, Esq., Surgeon to the Western German Dispensary, and formerly Externe to the Venereal Hospital, Paris.

(Continued from page 410.)

In 1832 Dr. Martin, a French physician, practising at Calcutta, had the idea of attempting the radical cure of hydrocele by injecting into the tunica vaginalis an iodated solution instead of weak wine. I have not before me the memoir in which Dr. Martin published his observations, therefore I am not aware whether this worthy practitioner alluded to my works as the source from whence he derived the idea of injecting a solution of iodine into the tunica vaginalis, in imitation of the injections of the same nature which I had had recourse to some years before, in cases of cold abscess and fistulous canals.

However this substitution has never appeared to me to be of much value. The diseases for which we are ignorant of a remedy are still so numerous that it is not wise in us to seek a new one for a disease that can be cured, in the majority of cases, by well known remedies which are always easily procured, no matter how we may be circumstanced in practice.

This, to say the least of it, useless substitution, was nothing more than—a circumstance to be remembered—an extension given to one of my modes of administering iodine, but it was adopted in Paris with an *eclat* it did not by any means deserve, and in the midst of which no allusion was made to Dr. Martin, whose name was eclipsed by that of a, no doubt, very learned surgeon, but whose memory, having been put to too great tests, has become forgetful of the labours of others.

However, experience cannot fail to do justice to these iodine injections. They possess no advantage over the vinous, the efficacy of which is attested by the best practitioners in all countries.

The injection of a solution of iodine into the tunica vaginalis, which has not even the merit of novelty, has, nevertheless, been extolled beyond measure. After having represented it as an actual advancement, as a more certain means of cure, and subject to fewer accidents than the vinous injection, a fact generally contested—it was asserted that this local application of iodine ought to be taken as an example. It is now described as a new channel open to investigators, and, consequently, it has been proposed to inject a solution of iodine into closed cavities, and into chronic abscesses, and it is declared, without hesitation, that these applications of iodine are without precedents, or rather that they have very naturally arisen from Dr. Martin's proceeding, but not a word is said about my writings (a). And yet, as regards all these, my researches were made several years previous to all the trials of this description which have been conceived by their so-called inventors, without any very great deal of trouble, for during the last fifteen years, and upwards, I have been in the habit of injecting ioduretted water into purulent cavities, after the pus has been evacuated by a puncture. They speak so much and in such high terms of this topical application of iodine, and pretend to be so totally ignorant of my works on this subject, that I have felt myself compelled to remind you of them on the present occasion, and for this reason I intend to make you acquainted with certain documents which will leave no doubt on the minds of impartial men as to the priority I claim, not so much for personal motives, as for the purpose of rejecting the exaggerations that are uttered at the present day respecting the radical efficacy of a local treatment in diseases, which, from their nature, are curable by no local treatment whatever.

I will extract from among the cases I have published in my memoirs that which relates to the injection of ioduretted water in cold abscesses and in fistulous tracks, in order to make the local treatment of certain symptoms of scrofula understood according to my doctrine, and to assign to it its rank and importance in the general treatment of scrofulous diseases.

Eloi Macaire, aged 22, presenting numerous and different symptoms of scrofula, had a fluctuating tumour larger than the fist, above the external extremity of the right clavicle, which passed beneath this bone to project in front of the chest. The communication between the two abscesses was easily detected by alternate pressure upon them. On the 12th May, 1830, the subclavicular abscess was punctured, and a pint of pus, or rather of softened tubercular matter, easily recognised by its purulent and caseous appearance, became discharged. After the puncture, which emptied both tumours at once, I injected into the cyst an ioduretted solution, and allowed it to remain for several minutes. The injection was repeated on the following days in the same manner. This patient had likewise several ulcers, which were dressed with the ioduretted ointment, and he was ordered the ioduretted water internally, and three sulphur baths a week.

Fifteen days of this treatment had the most desirable effect on the progress of the disease, the sides of the abscess became adherent, and have continued so ever since. The ioduretted treatment was, nevertheless, persevered in for several months, as this abscess was only one of the numerous forms of scrofula with which Eloi Macaire had been affected since his infancy.

Auguste Dubois, aged 18, entered the Hospital St. Louis on the 24th of August, 1830. Eight days afterwards the following observations were made relative to the injection of ioduretted-water.—A hard nodulated tumour occupied the whole of the right cervical region, unaccompanied by any change in the colour of the skin, or local heat, and producing a very painful compression on the subjacent parts, which it pushed on one side, although it still occasioned an external projection as large as two fists, the head was thrown on the left shoulder, and the skin being forcibly stretched, did not yield to pressure, which however occasioned but little pain, the œsophagus and trachea were also pressed upon, and deglutition and respiration in consequence impeded, so that the patient could swallow nothing but thickened fluids.

September, 1830.—Tumour punctured where the skin was thinnest, escape of a quart of pus mixed with shreds of albuminous matter. Injection of an ioduretted solution into the emptied cyst.

(a) The object in injecting the tunica vaginalis is to produce inflammation of its internal surface, by which its vessels become so modified and altered in their action as to be no longer capable of secreting too great a quantity of fluid. I apprehend, therefore, that any stimulating liquid calculated to bring about this result would be applicable to these cases. The wine diluted with water, the solutions of sulphate of zinc, of alum, of nitrate of silver, and iodine, and the solid nitrate itself, that have been hitherto used for this purpose, act in the same manner as urine or bile, for instance, do when they come in contact with the peritoneum, viz., as irritants. Therefore, and more particularly as the iodine has not, in my opinion, any advantages over the others in this respect, we need not restrict ourselves to it. The sulphate of zinc solution, when of proper strength, will answer every purpose, and has one great advantage in its favour, viz., cheapness.—TRANS.

Immediately after the puncture, the symptoms produced by the compression disappeared, and the patient could swallow and breathe with facility.

On September 20 the upper part of the purulent cavity was cicatrized. It was necessary, however, to open an abscess that had formed in a *cul de sac* of it, and from the dependent part of which the pus could not escape. The cure was accomplished on the 9th of December following.

In the month of September, 1830, I was sent for to a tradesman, aged 30, who had been confined to his bed for nine months. He was emaciated, his complexion straw-coloured, and his countenance expressive of despair, which those who waited upon him appeared to share in. I discovered four fistulæ on the upper posterior and outer part of the thigh. They were deep, but I could not ascertain to what extent with the ordinary probe, as the sight of an instrument made the patient tremble ever since it had been proposed to divide these fistulous tracks, which he had absolutely refused to submit to, notwithstanding the operation had been suggested by one of our most skilful operators. I contented myself with exploring their depth by means of ioduretted injections, which penetrated deeply into the soft parts after passing through numerous sinuosities. This local and investigating treatment was continued, together with the ioduretted water and baths. At the expiration of six weeks of this treatment the patient was able to go and take the shower and ioduretted baths at Tivoli. He returned to his occupation at the end of four months, and was restored at the expiration of the sixth. In this case the ioduretted injections were continued during nearly the whole of the treatment.

Louis Guillaud, aged nineteen, entered the hospital on the 18th of February, 1830, with a chronic abscess on the right external iliac region, and complaining of pain on the slightest motion of the hip-joint. A month afterwards I punctured this abscess, and a quart of pus escaped. Ioduretted water was afterwards injected into the cavity, and the outside of it rubbed with the iodide of mercury ointment. A chronic abscess which the patient had had since the month of September, 1829, on the inner side of the upper third of the thigh, had been opened at the Hotel Dieu, and had remained fistulous ever since, an enormous quantity of pus being discharged through the fistulous opening whenever the limb was moved. Two dressings would not have been sufficient, therefore I ordered the ioduretted water to be injected thrice daily, and the iodide of mercury ointment to be rubbed into the outside of the cyst. On the 10th of April there was no more discharge from the latter abscess; the fistula was dried up. The second fistula, which resulted from the puncture that had been made in the large abscess in the hip, was healed at the end of the same month.

Louis Mornon, aged eighteen, had a spontaneous luxation of the right femur, accompanied by two chronic abscesses, through the fistulous orifice of one of which fourteen fragments of the femur had made their escape. This patient was treated by the injection of iodine water into the purulent cavities. At the period when this case was recorded (June, 1828) I employed only iodine solutions, as I had not at that time discovered the formula for the ioduretted ones.

In my third memoir I have related several cases in which I have employed the ioduretted solution injections in cases of chronic abscess and fistulous tracks; and, after having recited these facts, I have recommended the general employment of these injections in all similar cases. The remarks made are as follows:—"I constantly order these spacious cysts, or chronic abscesses as they are called, to be punctured; and when the tubercular matter has been evacuated, I have them filled with an ioduretted solution two or three times at each dressing. After these injections, which it is evident are analogous to the injection of wine into the tunica vaginalis, the external parietes of the cyst are rubbed with either the ioduretted or the iodide of mercury ointment, and then covered with an ioduretted poultice as hot as the patient can bear it. Guillaud, Cheron, Durent, &c., were dressed in this manner."—(Third Memoir, p. 196.)

Thus nothing is more clearly proved than that my observations were made prior to those that have been in course of publication for some time past, relative to the efficacy of iodine water injections in cases of chronic abscess; and you have just seen that after I changed the iodine solution for an ioduretted one, in consequence of the progress I had made in my investigations, I daily employ it, the latter as an injection for cysts and fistulous tracks.

I have made several other applications of this solution; for instance, I make use of it as a collyrium in cases of scrofulous ophthalmia, for bathing the eyes, and for injecting behind the lids by means of a small syringe.—(Third Memoir, pp. 37 *et seq.*, Cases 5 and 6.) I likewise send a gentle current of the same solution upon the internal angles of the eyes, in order to excite in the lachrymal passages a degree of tonicity which corrects that state of atony and congestion so common in scrofulous subjects. I employ it also as a local bath in cases of coryza and ozæna, in which the patients sniff up the ioduretted water several times in the space of a few minutes. The manuluvia, the brachiluvia, the pediluvia, &c. &c., and all local baths of every description, were formed in the same manner.

In my Third Memoir (p. 186) I have given a receipt for an ioduretted solution for *external use*, in order to replace the iodine solution contained in the first. But, in consequence of the number of injections and iodine lotions required by our patients in the hospital, we no longer carefully weigh the proportions of iodine and iodide of potassium, but compose extemporaneously the ioduretted water, by pouring a sufficient quantity of the rubifacient ioduretted solution (a) into some water, so as to give it the colour of new mahogany. It is easy to judge of the quantity by the eye, and its employment is not attended with the same danger as when iodine is administered internally. The ioduretted water, composed in this manner at the bedside of the patient, serves for collyria, lotions, and injections, by means of which the local condition of the affected parts may be greatly improved.

All these local applications of iodine have been used in my wards at the Hospital St. Louis since the end of the year 1829, and are employed daily in numerous cases. Of this every one is aware, not excepting even those who entertain the learned societies and the medical press with some of them, as so many trials the results of their own imaginations.

Had it been necessary for me to claim merely an indisputable priority, I should not have interrupted the silence; but I had another intention of far greater importance than a personal satisfaction. I was desirous more particularly of pointing out the unfortunate tendency of these unintelligible and retrograde imitations, which, by showing a degree of ignorance of the true therapeutic properties of iodine, lead one to consider the drug and its preparations only as topical applications preferable to those at present employed.

Iodine is substituted for wine; and this substitution is extolled as a very valuable discovery, as a new mode of applying iodine, and as a stepping-stone to several other applications with which therapeutics are about to be enriched. But you have just seen that all these pretended new applications were made known more than sixteen years ago, and that all those which people pretend to foretel have been formally recommended, and formulæ given for them in the three memoirs I published in the years 1829, 1830, and 1831, on the employment of iodine in scrofulous diseases.

Nevertheless, these iodine injections, as also several other ioduretted preparations which are employed in the local treatment, and which I will not mention in this place,—all these topical applications, either together or separately, ought to have but a secondary place in the ioduretted treatment. This consists principally in the internal exhibition of iodine by means of the ioduretted water and baths, it alone is the radical treatment, and its power is but slightly increased by the addition of the local treatment,—an addition which is not absolutely necessary, inasmuch as we have cured scrofulous diseases without even touching the patients, who dressed their wounds themselves with dry charpie, over which was spread a thin layer of ioduretted ointment to prevent it from adhering too much to the soft parts.

You have perceived from the extracts from the cases of Dubois, Macaire and Guillaud, that scrofulous cysts had healed in a short time after being injected with ioduretted water. Why did I not publish the particular history of the rapid cure of these cysts? Because the patients were not cured; for although adhesion had taken place between the parietes of the cysts, the other concomitant signs remained. I should then have been strangely deceived if I had considered as cured patients in whom only one of the numerous signs of the constitutional disease with which they were affected had been made to disappear. These patients in reality were not better cured than a person, having several caries would be, on being cured of one of them after undergoing a few weeks' treatment.

The local means, whatever they may be, all belong to the method, and are valuable only by their timely employment in the application of this method to the different forms of the scrofulous disease. By separating them from this method, and representing them as particular modes of cure, we deceive ourselves and overlook in a measure the tubercular diathesis, without a thorough knowledge of which, we can only blindly undertake the treatment of the diseases which arise from it.

I hardly know how to express my surprise when I see it stated that chronic abscesses have been cured by one month's ioduretted treatment. I place all these particular cases in one category, and formally declare them to be impossible, in this sense—that if the abscesses are cured, the patients are not. I again repeat that the local is but an auxiliary to the internal treatment; the difference between the two being such that the most serious scrofulous diseases may be cured without any local treatment, while this, even when of a special and well-directed character, can produce only a slight amelioration, and that but for a short time.

Those practitioners who so highly extol the efficacy of idoated topical applications are influenced by a spirit of localization which cannot be too much condemned in medicine, their observations are so many erroneous cases which they spread over the field of science, and which are followed by the most unfortunate results in medical practice.

All scrofulous subjects who have been treated by local means are as scrofulous after they have undergone the local treatment as they were before, no matter what the immediate results may have been; their complexion has not changed; they have retained the same predisposition; and we are not long in having proof of it by the appearance of some other sign of the scrofulous cachexy. The practice of medicine abounds but too much in proofs of what I state; practitioners daily witness the occurrence of relapses in cases where cures have been obtained by local means, among which amputation unfortunately stands prominent, in consequence of the vast number of instances in which it is had recourse to. The illusion in this respect is so great that the discretion which almost every surgeon acquires by experience, and in consequence of which he becomes much more temperate in operating as he proceeds in his career, is not taken into account.

The patients, as we stated just now, retain the same complexion they had at first, although they appear to have been cured by local treatment; the fact is, this complexion can be altered only by a proper internal treatment, which must be persevered in for some time. As regards scrofulous diseases, I have laid down the mode of treating them by ioduretted preparations. By the aid of this method iodine may, I think, be administered with as much facility as any other remedy. But the manner in which this substance is generally prescribed in the present day is so opposed to the recommendations I have given that there exists the greatest confusion as regards its employment; [illegible] given, much to the injury of the patients, in

(a) Its composition is as follows:—℞. Iodini ℥ss. Potass. Iodidi, ℥j. Aq. distillatæ, ℥vj.—Trans.

incredible doses, and this abuse of a valuable remedy causes in medicine an actual disorder, in the midst of which practitioners know not which guide to follow, or to what rules to restrict themselves. (a)

MEDICAL CASES.

SUBJECT—DELIRIUM TREMENS.

(Continued from p. 432.)

CASE 1.—DELIRIUM TREMENS.—Ann Jones, aged 40, dressmaker.

Admitted May 20, 1845. Under Dr. Nairne.

Pulse 108; skin hot and moist; bowels open; tongue white and moist; urine scanty and high-coloured; countenance flushed, and expressive of great excitement; manner hurried; she is constantly pulling the bedclothes about and trying to get out of bed; she is sensible and answers questions, but in an abrupt manner, and immediately afterwards talks about other subjects; she has also tremors of the limbs.

Her friends state that from embarrassed circumstances, she fell into a desponding state and took to drinking. On the 15th she became much excited and could get no rest at night, and this continued until the day before her admission, when the attack came on.

℞. Morphiæ acet. gr. ss.; spir. æther. s.c. ʒss.; spir. lavandulæ c. ʒi.; mist. camphoræ ʒvjss.; 2ndis horis si non dormiat. To have a mutton chop and strong beef-tea.

21. Has had no sleep; is still greatly excited and trying to get out of bed; fancies she sees different objects which frighten her; manner still hurried, but she does not appear to be quite so violent; bowels open; tongue white. To have some bottled stout.

℞. Tinct. opii m. xl.; Aq. menthæ pip. ℥jss.; 2ndis horis si non dorm.

Eight p.m. Has just had a violent epileptic fit, which lasted only a few minutes, and she then slept for about an hour; after which she became calmer, and slept at intervals throughout the night. She took the last dose of opium at 7 P.M., so that she had taken ʒiij. ℈ij. before she had any sleep.

22. Much better; tongue white; pulse 96; skin very hot and perspiring; sweated much in the night; manner not quite so hurried; answers questions rationally; has twitchings of the muscles as if startled; is very thirsty; bowels not open. To have strong beef-tea.

℞. Tinct. opii m. xxx.; spir. æther s. c.; spir. lavandulæ C. aa. m. xxx.; mist. camphoræ ʒxiss. ter die.

23. Slept well; tongue cleaner; pulse 88, quiet; manner still quick, but she is not so startled; is still heavy; has less perspiration; bowels open.

24. Tongue white; bowels not open; slept at intervals through the night, complains of giddiness and swimming before the eyes; is more startled; perspires much, and complains of headache.

25. Tongue clean; slept pretty well, and is less agitated.

Rep. mist. bis in die.

27. Still complains of drowsiness; had a return of tremor last night, and was obliged to have some brandy; still rather delirious; slept pretty well; dreamed much; tongue white; bowels open. Spir. vin. gal. ʒij.

29. Complains of headache; tongue white bowels open. Rep. mist O. N. tantum.

pretty well; dreams much, bowels very open tongue clean.

June 3. Still much agitated, and dreams much; has starting of limbs at night; tongue still white; bowels open. Omit. spir vin. gal.

Rep. Haust. O. N. c. tinct. opii m. xl.

Rep. Haust. O. M. c. tinct. opii m. xx.

5. Looks better; has less appetite; is still restless at night; bowels open, tongue white.

Rep. Haust. O. N.

℞. Mist. camphoræ, ʒx; tinct. hyoscyami, m. xxx.; spir. ætheris nit. ʒj; spir. æther. s.c., m. xx., bis. die; haust. sennæ, ℥jss. cras mane.

7. Sleeps better; has less starting; tongue cleaner.

10. Tongue still rather white, but she is less nervous, and sleeps well.

11. Left cured.

CASE 2.—David Davis, aged 35, hair-dresser. Admitted June 18, 1845. Under Dr. Nairne.

Skin cold and clammy; pulse 96, soft and compressible; tongue coated in centre, red at tip and edges; eyes suffused; bowels open; urine free; superficial veins of face very turgid; he talks incessantly, and answers questions correctly, but immediately wanders to other subjects; he puts out his tongue almost before he is asked to do so; there are great quickness of manner and twitchings of the muscles; he has no tremors; he has had no sleep for three nights; there is no picking of the bedclothes, and he lies pretty quietly in bed; he is a hard drinker, gin being his principal beverage; he has had two previous attacks of the same kind, one four years and the other only six weeks ago; he has complained of pain in the loins for some years, and the legs have been œdematous for the last six weeks, but are not much so at present; abdomen somewhat swollen and contains fluid; skin of a yellow colour.

Seven p.m. Had an epileptic fit, accompanied with strabismus, his evacuations passing under him; the fit lasted ten minutes; afterwards he was more delirious, very irritable, and began picking the bedclothes.

Ten p.m. ℞. morphiæ acet. gr. ss.; spir. æther. nit. ʒj. statim. Haust. sennæ, ʒjss. o. m.

19. Fell asleep about an hour after taking the morphiæ, and slept till four a.m., but not soundly; is more composed this morning; manner less hurried; eyes less suffused; talks less; no picking of the bedclothes; is perfectly sensible, pulse 96; bowels well opened; urine small in quantity and high-coloured; perspires much. Spir. Genevæ, ℥vj.

Rep. haust. nocte et mane.

20. Very delirious in the night; running about the ward, and trying to jump out of window; has vomited some green matter; is quieter this morning; eyes more ferrety; more agitated; talks more; fancies he is at work; has more twitching of the muscles, and is continually getting out of bed; he sweated much in the night; pulse 88, very full and soft; tongue cleaner; urine very thick, depositing a pink sediment; there is no albumen in it.

One p.m. ℞. Tinct. opii m. xxx; spir. ether, s.c., m. xxx; mist. camphoræ, ʒxi. statim et 6tis horis. Mutton chop and bottle of stout.

Half-past 11 p.m. Became furiously delirious; trying to bite the nurse, and getting out of bed; fancying the house was on fire. Strait-waistcoat obliged to be put on.

21. Had no sleep; delirium continues, but he is more exhausted; constantly talking, and swearing at the nurse; has made no water since 6 p.m. last night; catheter passed, and about ℥ij. of thick urine drawn off; perspires profusely; bowels not open; abdomen hard and tympanitic; sordes on teeth and lips; pulse 120, quick and soft; tongue still loaded, moist; urine contains a little albumen; does not take his chop. Two bottles of stout; spir. vin. gall. ℥iv. ℞. Pil. colocynth c hyoscyamo, gr. x. statim.

22. Had a sleepless night; was very restless, and furiously delirious at *intervals*; countenance pale and haggard; more sordes on teeth and lips; has a slight cough; breathing hurried; sweats profusely; tongue red and dry; pulse 131, fuller; abdomen softer; bowels well open; very small quantity of urine drawn off; there is a great *prostration* strength. Aug. spir. vin. gal. ad ʒviij.

℞. Spir. æther. s. c., m. xx.; camphoræ gr. v.; Mist. acaciæ ʒij.; tinct. opii ʒj.; aq. pimentæ ʒix. post hor. ij. et rep. vesp. To have an egg. Omit. alia.

Seven p.m. Had two epileptic fits following closely; each lasted ten minutes; he then became comatose, and remained so till ten p.m., when he threw up some blood from the mouth, and died instantly.

SECTIO CADAVERIS.

Thorax.—Old and very extensive adhesions, uniting the right lung to the sides of the chest; the lung itself was throughout its whole extent loaded with large quantities of red frothy serum, except at the back part of the lower lobe, where the structure was condensed by red hepatization, and soft in texture. The left lung was also loaded towards the back part with red frothy serum, which came out in large quantities when the parts were cut. In both upper lobes there were on the surfaces of the lungs depressions with puckered edges, where the tissue of the lung was condensed, and contained several tubercular deposits. No tubercular matter was found elsewhere. The heart was pale in colour and soft in texture; all its cavities were dilated, but without any hypertrophy of its walls. Both the aortic and mitral valves were slightly thickened and somewhat contracted. The other valves were healthy. The blood contained in the cavities of the heart was fluid and very thin. A few patches of erythema existed at the root of the aorta.

Abdomen.—The peritoneal cavity contained a small quantity of dark-coloured serum. The liver was of a fawn colour throughout its whole extent; its margins were rounded, and its surface presented a well-marked granular appearance; when cut into, the structure of the organ presented a variegated appearance from the condensation of the cellular tissue, which in several places had separated the acini and compressed them. Both kidneys were large and congested on their surfaces and lobules; the capsules peeled off easily, and their surfaces presented in several places slight depressions, as if the cortical structure had disappeared; in the other parts the surfaces were perfectly smooth. Other viscera healthy.

Cranium.—The dura mater was more than usually adherent to the calvarium. The subarachnoid cellular tissue and pia mater were filled with large quantities of clear fluid. The cineritious substance was pale, and the white matter presented slight venous congestion. The ventricles were not enlarged, and the structure of the brain appeared to be perfectly healthy.

REMARKS.

Delirium tremens is unfortunately not at all uncommon, but at the same time it is necessary to be careful and prompt in our diagnosis, for there is a disease with which it is sometimes confounded, and to which in some points it certainly bears a strong resemblance: I allude to inflammation of the brain and its membranes; in this case the most active antiphlogistic treatment must be at once employed; but in delirium tremens this plan would only aggravate the disease and bring it speedily to a fatal termination.

(a) Some short time since, M. Berard related to the Société de Chirurgie a case of hydrops-articuli, or hydarthrus, arising apparently from disease of the cartilages, where he had effected a cure (after various other remedies, both local and general, had failed) by means of an iodurctted solution, composed of iodine 5 parts, iodide of potassium 5 parts, alcohol 50 parts, and water 100 parts, injected into the cavity of the joint, its fluid contents having been previously removed by a trocar introduced in an oblique direction. A good deal of reaction followed the operation, and the knee became still more increased in size; it gradually, however, diminished to a certain extent, and then remained stationary. On the 24th day after the injection, M. Berard made a second puncture, which gave exit to a reddish-coloured serosity, smelling strongly of iodine, and containing numerous bodies resembling split rice. A second injection was then administered, and the punctured wound closed, as in the first instance, with a piece of diachylon plaster, and covered with a bandage dipped in cold water. As no tumefaction or fresh accumulation of fluid had taken place at the end of a fortnight, the joint was placed in a dextrine bandage, and retained there for about three weeks, at the end of which time the patient was able to leave the hospital.—TRANS.

This disease is well illustrated in cases (1 and 2).—Ann James was admitted with all the usual symptoms of delirium tremens; countenance flushed and bearing an excited expression, could answer questions correctly, but immediately wandered to other subjects; she had tremors, and was continually picking the bedclothes, her manner was hurried. Now, these are the common symptoms in most cases of this kind. There are, however, one or two points which mark the difference between this disease and inflammation of the brain and its membranes: there is the same want of sleep in both cases, and there is delirium; but in encephalitis the delirium is constant and generally violent, and the patient cannot answer questions rationally; the pulse, too, is hard and frequent, whereas in the other it is generally soft and compressible; the skin, too, is dry and parched, and here arises our great mark of distinction: in delirium tremens the skin is always moist, and generally there is profuse perspiration. In delirium tremens there is always a peculiar hurried manner; the patient is exceedingly anxious to do everything quickly; he will start upright in bed at the appearance of his medical attendant; he will thrust out his tongue almost before he his asked, and perform every action in the same abrupt manner. In addition to the symptoms which mark the attack, our diagnosis is generally confirmed by the previous history; we almost invariably find that the patient is an inveterate drunkard, and frequently that the accustomed stimulus has been suddenly cut off. How many striking examples of this do we not see in surgical cases. A drunkard meets with an accident, he is restricted as to his diet, and his stimulus is stopped; an attack of delirium tremens is the consequence; and this, perhaps, is the first thing which opens our eyes to the patient's previous habits, for there is frequently a great desire to conceal the fact, probably through shame.

In the treatment of this disease our grand object is to obtain sleep, to soothe and calm the excited state of the nervous system, and in this manner alone can we ever hope to effect a cure. Opium is our great sheet-anchor, and I am inclined to think, from watching the effects of the various preparations, that the tincture is the most efficacious. The occurrence of sleep in most cases enables us to give a favourable prognosis. It is not always, however, that we can obtain sleep for our patients by the administration of opium alone, and then, to use the old expression, we must give them "a hair of the dog that bit them"; often some good bottled porter, or a strong glass of brandy-and-water, will at once produce the effect. In the case of Jones there was no sleep till she took some porter, in addition to the laudanum; she then slept, and from that time became calmer, her symptoms abated gradually, and she recovered. The case of David Davis was not, however, so successful, and, considering all circumstances, we could hardly expect that it should be so. In the first place, it was his third attack; and, in addition to his delirium, he had disease of the liver and kidneys. He, however, slept, and we might therefore have had some slight hope of his recovery, inasmuch as it showed that his system could be affected by anodynes. This man died, but I do not intend to say much concerning the post-mortem appearances in this paper, as I wish to reserve them to illustrate another subject. There was considerable venous congestion in the brain, and effusion into the sub-arachnoid cellular tissue, which are exceedingly common appearances in the brain of a drunkard. I shall not make any remark on the appearances of the liver and kidneys, at present: for although, no doubt, they were caused by his intemperance, yet they do not necessarily occur in these cases.

NAVAL APPOINTMENTS.—Dr. David Graham Miller, to be Surgeon of the Sidon. Mr. W. T. Domville, to be Assistant Surgeon of the Excellent, Mr. George J. Roberts, to be additional Assistant Surgeon of the Vindictive. Mr. W. Evans (b- acting ditto. Dr. Archd. Armstrong, additional Acting Assistant-Surgeon of the Caledonia. Mr. Augustus R. R. Preston, ditto. Mr. Andrew Clark, additional Acting Assistant-Surgeon to the Victory,

KING'S COLLEGE HOSPITAL.

CASE OF PUNCTURED WOUND INVOLVING THE KIDNEY.

Reported by HENRY SMITH, Esq., House Surgeon.

John Sullivan, a tall athletic Irishman, aged 26, was admitted August 17.

Whilst at work he had some words with a fellow-countryman, who pulled out a long clasp-knife and struck Sullivan twice in the back. The loss of blood was great, and he fainted before he was brought to the hospital.

On examination there were found two punctured wounds: one just below the inferior angle of the left scapula, about half an inch in length. On examination with a probe, the wound was found to run upwards and inwards underneath the muscles and integuments to the extent of three inches. The other wound was situated between the ninth and tenth ribs of the same side; the puncture was of the same size and shape as the other. A probe could be passed upwards and inwards to the extent of five inches, towards the spine, underneath the muscles, above the ribs. Although a most careful examination was made, the probe could not be passed underneath the ribs; the wounds were therefore considered to be superficial; they were dressed with water-dressing, and strict quietude was enjoined.

At twelve P.M., five hours after his admission, I was called to him, and found him rolling about in the greatest agony. He referred the pain to the situation of the lower wound; he could not bear the least pressure there. Whilst I was examining him the nurse showed me the urinal, which was half full of bloody urine which he had passed before I was called to him. There was no vomiting; he had great thirst; pulse 80, pretty firm. I ordered twelve leeches to be applied over the region of the kidney, hot fomentations to be used constantly, and the following powder to be taken directly:—

℞ Hyd. chlor., gr. v.; P. opii, gr. j.; P. antimonii, co. gr. iij., m.

18th. He felt great relief from the leeches, and after taking the powder he fell asleep for several hours. He complains of pain, which is much aggravated by pressure over the situation of the kidney in the track of the wound. There is still a considerable quantity of blood coming away by the urethra; has some pain in the left side whilst taking a deep inspiration, and he is troubled with a hacking cough. Continue fomentations. ℞. ant. p. tart., gr. ¼, 4tis horis.

19th. Much better; pain in back is less, but the urine is still very bloody; feels pretty comfortable; cough rather troublesome; there is a little moist crepitus heard at the lower part of left lung. Repetat.

21st. He is progressing very favourably; the urine is much less bloody; he complains of pain in the lower wound; his appetite is good, and he does not appear to have suffered much from the loss of blood he has experienced; cough is better, and pain in the chest less.

℞. Mag. sulph. ℥ij.; vin. ipecac. m. xx. ter die.

24th. Urine merely dusky; he feels pretty well, with the exception of some pain in the back, and weakness. He is allowed to get up.

26th. He is so well as to be able to go to the police-office to prosecute the man who stabbed him. The wounds are not entirely healed; urine clear. 29th. Discharged cured.

This case presents one or two points of interest. In the first place, wounds of the kidney are rather rare cases in civil surgery. It is not so much exposed to injury as the other important organs of the abdomen and chest—at least, to an injury of the kind received. In the next place, it was not considered, when the man was first admitted, that any important part had been injured; as careful examination with the probe showed that the wound was only superficial. But there can be no doubt, from the symptoms and from the situation of the wound, that the kidney was injured. Fear was at one time entertained that the pleura was punctured, from the pain in respiration and the cough; but those symptoms soon gave way under the use of a little tartar emetic; and it seems probable that the membrane lining the chest escaped injury.

TO CORRESPONDENTS.

A Student in the Country *will see the prospectuses of the London and Birmingham Medical Schools advertised on the cover of the* Medical Times. *We can give no opinion on their respective merits. If our correspondent desire to become a "distinguished" student we should advise him to devote all his time during his residence in town to the study of his profession.*

Mr. Clarke. *Two medical directories were published in January, 1846; one only professed to give the qualifications and addresses of medical men residing in London and its immediate vicinity; the other proposed to give a list of all members of the profession practising in England and Wales. The "London Medical Directory" was published by Churchill, and was a second time issued in Jan., 1846, the "General Medical Directory" was published in 1845, and has not since appeared. We presume, therefore, that it is the latter for which circulars have been lately transmitted to members of the profession. Neither of these works was quite perfect, but the "General Medical Directory," on account of the greater extent of its scheme, and the greater difficulty of obtaining correct information from remote parts of the country, from the absence of post-office directories, was considerably the more incorrect of the two. A report of the successful progress of the* NATIONAL INSTITUTE *will be found in another column.*

Mr. H. R. Collier, M.R.C.S., thus writes:—*"Having, by chance, yesterday, looked over the last few numbers of the* "Lancet," *I was much surprised to see some remarks regarding the distribution and value of the prizes at the Westminster Hospital School of Medicine. Of the distribution, certainly nothing can be said; but of the prizes I feel myself called on to contradict the statement of* 'A Pupil' (?). *I received, as the midwifery prize, a very handsome case of obstetric instruments from Drs. Bird and Andrews, and two handsome volumes of the* 'Standard Work on Medicine,' *by Dr. Watson, as a prize for that subject, from Dr. Roe. I feel it would be injustice to those gentlemen, after the published statement of* "A Pupil," *did I not contradict in as public a manner his assertion."*

An Observer.—*The "great unknown," whose authority was mentioned by the coroner, is probably not in existence.* "Quackley" *was sufficiently cautious to suppress all reference to his name. We never read the* Satirist.

A General Practitioner.—*The notice of the judge is disgraceful.*

A Pupil at the Westminster Hospital.—*We are quite aware of the proceedings of the "healthy skin" gentleman. The governors of the Westminster Hospital are too clear-sighted and independent to be imposed on by* "pulpy softening."

Several communications have been received, and are under consideration.

Medicus.—*We shall next week publish the report of any proceedings at the meeting of the British Association that may be interesting to our readers.*

Studens.—*The National Institute.*

An Admirer *should write to the secretary of the college.*

A Poor Patient.—*We never prescribe in the* Medical Times. *Our correspondent may obtain advice by applying at any of the Metropolitan hospitals.*

The secretaries of the medical schools in London and the provinces are requested to transmit their prospectuses without delay to the editor of the Medical Times, *in order that abstracts of them may be made sufficiently early for insertion in the students' number of that Journal.*

F.R.C.S.—*The Library of the College of Surgeons will continue closed until the commencement of the winter session.*

☞ *Gentlemen in arrears are requested to forward their subscriptions during the ensuing week, in order not to be entered in our list of defaulters.*

THE MEDICAL TIMES.

SATURDAY, SEPTEMBER 12, 1846.

> "Hic mecum licet, hic juvence, quicquid
> In buccam tibi venerit, loquaris."—MARTIAL.

THERE are certain seasons when news and novelty are so scarce, they are not obtainable at any price. The present happens to be one of them. Nothing just now is in the ascendant but what everybody knows, and nobody thinks worth talking about. Things, or rather topics, have literally reached their level; to go ahead is about as possible as to square the circle; there is no wit worth laughing at, and no wisdom one cares to listen to. The "busy world," that poets and fiction-mongers are fond of making a fuss about, seems to have laid by business altogether, determined to have one of those periodical naps that appear to be necessary to its renovation. Like a great sea in a calm, it lolls lazily, seeming to care not a fig whether it ever "wags" again, and coolly leaving us, its deserted offspring, to get over it, or through it, as best we can.

Parliament is regularly "used up"; and St. Stephen's, as deserted and disregarded as though it had never flourished respectably in the annals of topography. "Members" are scattered hither and thither—some trying to get rid of their accumulated carbon, and infuse a little warmth and freshness into their parchment skins, by wandering over hill and dale in search of any stray partridge that will give them a chance of a shot; and others are rolling about in their easy chairs, or snoring away in bed, in the hope of recovering the complement of sleep and rest they lost in listening to the tedious twaddle of last session.

Lecture-rooms are shut up, professors are at play, and skeletons swing idly in dusty museums, to show that anatomy and its kindred sciences, at this particular time, are at a discount. Physicians and surgeons walk mutely through the wards of their respective hospitals—for there are no students to prompt them to clinical eloquence, by gaping and staring for any words of instruction they may casually drop.

Booksellers have little to do, and less to sell. The periodicals, medical and miscellaneous, are born at their respective seasons—but few of them are free from sickliness or debility, and many are palpable abortions. Sundry that we could name appear to have reached the "turn of life," and suggest to patrons and proprietors the unpleasant probability that their days of increasing and multiplying are all numbered. In the systematic work or text-book line there is little astir. Scribbling is not out of date—but it would seem, by implication, to be out of fashion. Authors are either too poor, or publishers too wary, for that autumnal outpouring of new works on physic that was so customary a few years back. Not that we think the world loses anything by the absence of this literary profusion—perhaps we should be better off in our libraries if nine-tenths of the scribblers who have wasted ink and paper had never known the scholastic use of either.

As we have said, everything seems to be "weary, stale, flat, and unprofitable." However it might be in Solomon's time, there clearly "nothing new under the sun" among us. The cholera, as folks call it, excited a little commotion and rumbling awhile ago; but it appears to have got tired of draining the community, and is lazily dying a natural death. The Hounslow inquest was certainly something novel—but, as it was *past a joke*, we must not pause in our good nature to treat it lightly.

In a dearth of matter of fact like that we complain of, what is an editor to do for the edification of his readers? And, as there is an equal dearth in matters of fancy, what must he do for their amusement? If any wiseacre says, "Write about nothing," we tell him to try the experiment himself, and see how he likes it! To write about anything is a task of some trouble to most people; but to perform a similar feat about nothing goes beyond all we profess to be master of. *Litera scripta manet* is an old axiom, that has often curbed the impetuosity of an author's pen; when thoughts get upon paper they are very much like being stereotyped—there is no saying what criticising they may get. A jocose old classic says, a man had much better *talk* like a fool than *write* like one: for this reason it is that, when authors have nothing to deal with, silence is their best safeguard. But an editor, unlike authors in common, is not his own master; and worse than this, he has more people to please than are always easy of gratification. If he have really nothing to write about, nobody believes him—or at least he is not allowed to plead the Lucretian pretext—

> "Nihil igitur fieri de nihilo posse fatendum est."

Unhappily for us, we belong to that old-fashioned race of writers who can draw inspiration from nothing but ourselves. Were we like Horace, a bowl of Falernian might prompt our genius; like Johnson, Pitt, or Sheridan, an inferior grape might serve us; like Fox, its distilment, known as brandy, would suffice; like Byron, gin-and-water would supply our nothingness; like Pope and Fontenelle, we could derive the same aid from coffee; like Newton and Hobbes, from the fumes of tobacco; like Hall, from strong tea; and like Haller, from copious draughts of cold water. Alas! we are not like any of these said worthies, and therefore cannot be expected to do in any wise as they did. Of course, then, in the absence of a text or theme, we can scarcely be required to furnish a very definite discourse. . . . .

We were about to throw down the pen altogether, to make our bow for the week, and ask our readers to hope better things from us another time, when it occurred to us to remember that the annual incubation of the British Association is now taking place at Southampton. Faith, here's a subject ready made, and one that is as empty as need be! If we manage to write upon this, in good truth we shall have composed something upon nothing. Think of that, revered shade of Lucretius!

We wonder how Southampton feels, and what it thinks of itself, now it has got within its precincts the august body composing the British Association for the Advancement of Science! How the old walls of the venerable place must tremble and quake, on the contemplation of the awful advances that science may possibly make within their hearing, in the course of one short week! We should not be surprised if the overwhelming influx of knowledge were to prove too much for the old place, and tumble it down about its own ears. We know that "knowledge is power," and this latter is somewhat synonymous with "physical force"; so that there is really no saying what the consequences may be of letting off too much discovery at once! Moreover, when we consider how many "great guns" are gone, open-mouthed, ready charged, and primed, fully intending to fire their best, it is quite a matter of doubt what the concussion will amount to. The quantity of smoke, again, will be very serious—stifling we should say! We trust, however, that the larger and more intelligent guns will see the propriety of keeping close together, and firing in due succession; at the same time having their eyes, or their mouths (which mean the same thing), warningly directed towards the smaller fry—pistols, popguns, and so forth—to keep them in obedience until their proper time for going off shall have arrived. On the arrival of that said time, the sooner they are gone off the better!

It is said that Prince Albert intends to honour the Association with his presence. No doubt Science, in the abstract, will consider herself very much obliged to his Royal Highness for the gracious notice he condescends to take of her. Of course, royalty generally has a sort of inherent title to intellectual distinction, without the trouble of working for it, like ordinary people; or, were it not so, we should very much like to have heard that the Association had been favoured, not only with the presence of Prince Albert (in which it is not distinguished above the opera), but with some trifling contribution from the royal pen. Princes may afford to make a joke of knowledge, because they have enough and to spare; but ourselves, who are more scantily provided, are glad to catch all we can. Any trifle from regal quarters would be thankfully received.

Of course there will be the usual influx of our continental neighbours, bringing plenty of information, and going away laden with something much more substantial. Names of all sizes, and of all possible varieties of pronunciation, are advertised to appear; the only anxiety we feel, is for the poor waiters, and others in minor offices, whose duty it will be to give utterance to these strange denominations.

One of the chief features connected with the meeting of the British Association for the Advancement of Science, is its gastronomical department. So transcendent is it in this line that it might be a *coterie* of cooks, rather than an aggregation of all the literature and science the world has in it. The fact, however, is curiously illustrative of an old physiological axiom, which tells of the great sympathy between the stomach and the brain. Of course guns cannot be expected to go on shooting for ever—they must become exhausted, and then they must be filled again. So it is with man! When

he has emptied his brain, he forthwith makes up for it by filling his stomach. The terrible onslaught upon the head that the members of the British Association will no doubt suffer from, will make it incumbent upon the Southampton people to relieve by as ample gastronomical supply as they can get. It has always been usual to furnish these said things in profusion, and we have never yet known them wasted.

"Quid dignum tanto tibi ventre gilaque pieralor?"

Whilst, however, the roar of intellectual artillery is going on deliciously upon the coast we trust that some slight reverberation or echo may reach us who remain more inland. We have always thought it too bad for the Association to be so avaricious of its mental wealth. This is a commodity it overflows with, and yet it refuses to give any of its treasure away! The stock in hand must be enormous—our wonder is how they find warehouse room for it! Of course a great deal that has never seen light must, by this time, have got very mouldy, and therefore, the Association may not like to expose it. In consideration, then, of its venerableness, it is quite welcome to remain *in statu quo;* but we do earnestly entreat that, for the future, the Association will be less niggardly of its riches, and give us something, though it should be merely the skimmings, of its ample ocean of scientific wealth.

MEETING OF THE NATIONAL INSTITUTE.

A well-attended and highly-influential meeting of the members of the National Institute was held at the Hanover-square Rooms, on Wednesday evening, September 9, for the appointment of treasurer and trustees, and for the consideration of the measures requisite in order to elect a council to conduct the affairs of the Institute.

Mr. Clifton moved the first resolution—"That R. R. Pennington, Esq., be requested to take the chair." This, he said, was due to the venerable gentleman who had presided over so many meetings since the establishment of the body now about to merge into the NATIONAL INSTITUTE OF GENERAL PRACTITIONERS IN MEDICINE, SURGERY, AND MIDWIFERY. The resolution was carried by acclamation.

Mr. Bonney then moved, "That George Ross, Esq., be appointed Secretary *pro tem.*" Mr. Bonney, in proposing this resolution, paid a well-merited compliment to the zeal and ability with which Mr. Ross had filled the office of secretary to the National Association.

Mr. Lobb seconded the resolution, which was carried unanimously.

Mr. Pennington then rose, and, after explaining the purpose of the meeting, said that he held in his hand a letter from Messrs Bird and Ancell, which, if it were the pleasure of the meeting, he would read to them.

The letter was then read, as follows:—

"TO THE MEMBERS OF THE NATIONAL ASSOCIATION OF GENERAL PRACTITIONERS IN MEDICINE, SURGERY, AND MIDWIFERY.

"GENTLEMEN,—The National Association having accomplished a most important object in furtherance of the cause of medical reform, by the proceedings of the general meeting held on the 12th day of August last, the period has arrived when the duties which have devolved upon us for nearly two years as your honorary secretaries are necessarily brought to a conclusion. We beg leave to be permitted to address you a few lines on retiring from our office.

"In the latter part of the year 1844, when a Government bill for the regulation of the medical profession was before the public, our highly esteemed president, R. R. Pennington, Esq., supported by several influential general practitioners of Marylebone, and a number of the leading members of that branch of the profession of the city of Westminster, held a meeting for the purpose of considering the necessity and the practicability of organizing the great body of the profession, to watch the progress of medical legislation, and to place the general practitioners in a position to communicate their views to the Government and the colleges, with that weight and authority which a combination of intelligent and educated men ought to possess, in matters deeply affecting the interests of their own particular body. At that meeting it was resolved that an effort should be made to form a Voluntary Representative Association, for the purpose of effecting those objects which the interests of the general practitioners demanded; and a public meeting was accordingly convened, at which meeting, among other matters, it was determined to endeavour to effect a union between the various metropolitan and provincial associations formed for similar purposes. This meeting constituted the nucleus of a more general combination, which ultimately became the National Association, and numbered between four and five thousand members. The union and organization of the general practitioners were regarded as an indispensable step to secure an efficient measure of medical reform.

"When Mr Pennington took the lead in this great movement, we were requested by him and the provisional committee, and subsequently by the numerous and highly respectable and influential committee to which the affairs of the association were intrusted, to act as honorary secretaries. Feeling strongly the obligations which the profession was under to a body of gentlemen who could have no motives of personal interest or ambition to serve in standing forward to fight the battle of the public for a high standard of qualification on the part of every individual authorised by law to practise medicine and surgery, and thereby to secure the true respectability of the great body of the profession, we expressed our willingness to give our best exertions in any way the committee might deem most desirable, but with considerable misgivings as to our ability to perform the duties which the importance of the cause and the urgency of the case might require at our hands. The turmoil of political agitation of any kind was contrary to our habits, and must necessarily prove a great interruption to our ordinary avocations. The request entailed upon us obligations which we feared no efforts of ours could adequately discharge; but feeling that, in the impending struggle, great interests were at stake, we regarded it as a duty incumbent on every individual to do his best in aid of the common cause. It would have afforded us the greatest satisfaction if individuals more competent, and with more ample time at their disposal, had been selected for the office.

"We need not remind you, gentlemen, how rapidly business accumulated upon us. The organization was achieved in an almost incredibly short period; other and graver duties arose, requiring still greater exertions, and making much larger demands on our time and attention. Stimulated, however, by the example of our venerable president, and animated by the zealous and disinterested labours of the committee, who have devoted their time and attention unremittingly to the important business of the association, we could not relax in our efforts or press our resignation, although, like other members of our arduous profession, we had our daily routine of professional engagements. Upon every occasion we have endeavoured to carry out the wishes of the committee, of the local secretaries, and of the members of the association, to the best of our judgment and ability; but if in individual instances any apparent want of attention to the various communications or suggestions with which we have been honoured has occurred, we beg to express our sincere regret, and trust that it will be attributed to the causes above stated. The kind consideration we have at all times experienced from all with whom we have co-operated, and the handsome manner in which our exertions have been acknowledged at general meetings of the association and by the committee, are an ample reward for the services which were required of us; and the approbation expressed by our professional brethren on those occasions will ever be held in grateful remembrance by us.

"The discussions, the correspondence, and the negociations in which we have been engaged, have necessarily brought under review the whole bearing of the medical question, and our opportunities have been calculated to make us acquainted with the various opinions entertained by our professional brethren on the subject of medical reform. It would be presumptuous in this valedictory letter to intrude our individual opinions on the different questions which have been so warmly agitated during the late attempt at medical legislation; but we cannot help remarking that a patient and careful consideration of the causes which operate, both favourably and prejudicially, on the medical profession in this country, has led us to the firm conviction that a measure of medical reform which would promote the interests of all classes is attainable by the profession. We are satisfied that the evils which the profession labours under, and the obstacles to a reform, have depended, in a great measure, upon the profession itself,—upon corporate jealousies, mutual distrusts, and conflicting interests; and especially upon a miscalculation, on the part of corporate bodies, of the feelings, customs, habits, opinions, prejudices, and requirements of the community, as respects sickness and health, and a consequent misapprehension of the interests of the public as respects the great body of the profession—the general practitioners.

"The members of the association, and of our own class in the profession, will allow us to remind them that our venerable president has been engaged in general practice for upwards of sixty years, and throughout that period has enjoyed the confidence—the entire confidence, in matters of life and death—of a most numerous circle of patients and friends, including many of the most highly educated and highly gifted individuals which this or any other country ever produced. No class in the profession can bring forward a name that can boast a higher reputation or more successful career. The general practitioners, of whom Mr. Pennington is the exemplar and the type, are the physicians and surgeons of the great mass of the people of this country; they are educated for the performance of all the duties of the physician, the surgeon, and the accoucheur; their assistance is sought for by the public on all occasions; their advice is acted upon in the most important stages of disease; they take the entire responsibility in every department of practice, and in the performance of these functions they have obtained, as a class, the confidence of the community.

"As humble members of this numerous—this essential—this highly important and useful body of men, recognising, in an educational and scientific point of view, no distinction between the practice of physic and the practice of surgery—a body hitherto possessed of no corporate rights or privileges, no home of their own—we congratulate our coadjutors that their organization, which took its rise, and was to a considerable extent matured, to serve the purposes of an emergency, is not to be broken up. It is a subject of unmixed satisfaction in our minds, that the object for the attainment of which our best energies, with those of your committee, have been directed during the late excited period, is to be fully carried into effect, and that the National Association is to be rendered permanent as a 'National Institute of Medicine, Surgery, and Midwifery.'

"We earnestly hope that the Institute will not only be permanent, but powerful also; that the whole body of respectable general practitioners in the kingdom will join it, and contribute by their unity and exertions to effect those ameliorations in the profession so much demanded. The union of some thousands of educated men in a voluntary representative institution must be irresistible for the attainment of all just and reasonable objects. In conclusion, we trust that our desire to see our own class established in its rights and privileges will never be misconstrued into any want of respect for the other classes in the profes-

sion. The elevation of the profession as a whole must ever conduce to the true respectability of all its parts. The failure of the recent efforts at medical legislation will, we earnestly hope, be a guarantee against any future attempt on any other principle, than that of elevating the literary and scientific character and the social and political importance of the whole profession; and we trust that the establishment of the National Institute will enable the general practitioners to secure that position in any new arrangement of the medical institutions of the kingdom which their extensive sphere of usefulness so fully entitles them to hold.

"Gentlemen, with every wish for the prosperity of the National Institute, the interests of which we shall ever have at heart, and shall use our best exertions to promote, and again thanking you for the cordial and unanimous approbation you have manifested for our public services,

We beg to subscribe ourselves,
Most respectfully,
Your obedient humble servants,
"JAMES BIRD.
"Sept. 8." "HENRY ANCELL.

Mr. Propert, in moving the first resolution, said that no explanation of it was required. The resolution spoke for itself. He then read the resolution as follows:—

Resolution 1.—"That John Dodd, Esq., and Edward Tegart, Esq., be requested to act as treasurers to the National Institute, and that the treasurers be two of the trustees of the property of the Institute."

He considered nothing would be of so much importance to the new Institute as the appointment of good officers to conduct its affairs. All knew how well the gentlemen who had acted as treasurers to the National Association had fulfilled their duties, and he hoped to see the affairs of the National Institute, into which their association had that day merged, as well conducted—he did not believe it could be better done. The first association had originated in a "sky parlour" in the parish of Marylebone, and, from its infancy to its present maturity, the treasurers had spared no pains or exertions in its service. Without ammunition no good could be done, and without fit and proper men to distribute that ammunition it would be of little use. He hoped the Institute would give its treasurers full employment for years to come.

Mr. Liddell seconded the resolution, which was put, and carried unanimously.

Mr. Squibb, in proposing the second resolution, would make but few remarks. He wished to impress on the gentlemen present that the National Institute was to be a permanent union—an organization of the general practitioners which should be a perpetuity—an organization that should keep up the dignity of the profession, and one without which the general practitioners, as a class, would be lowered by the colleges. He would read the resolution:—

Resolution 2.—"That James Clayton, Esq., and Thomas Davies, Esq., together with the treasurers, be requested to act as trustees of the property of the Institute."

He looked forward with hope that in a very few years the Institute would be in possession of a large amount of property, in the shape of books, preparations, &c. He hoped that each member would look on the Institute as a matter of personal property—as a new house—and that each would contribute with the same zeal as if he were furnishing a new house.

Mr. Brown perfectly coincided with Mr. Squibb on the subject of making each member's interest in the Institute a personal matter. The general practitioners had been the last branch of the profession to unite, and consequently they had hitherto been insulted by the colleges, and treated with indignity by all parties. They had seen the Pharmaceutical Society established around them, and formed into a firm organization; they had seen its representatives, when any measure affecting the rights of the body had been brought forward by the Legislature, come boldly forward, and heard them say "We will not have it so." Then, again, just without the bounds of the profession, they had seen the Association of Veterinary Surgeons gradually rise into an improving profession, gradually acquire a *locus standi* with the public, and gradually become a scientific body. General practitioners, on the other hand, forming a body large enough to swallow up all classes of the profession, had hitherto had no point of union. He trusted that, for the future, an organized body would exist, which would be listened to with respect by all classes. It would be of great moment to form the Institute, before the next session of Parliament, into a perfect body; and he hoped that all practitioners, from all parts of the country, would come forward generously in its support. He hoped that all—both country and town practitioners—would now be united in one general HOME. A few years ago this would have been impossible; but even now, with the great facilities of railroad communication at present existing, centralisation by no means equals what in three or four years it must become. He was convinced that in a few years the National Institute of general practitioners would form an organization containing a class of men of such standing that no body, corporate or otherwise, would be able to avoid treating them with consideration and respect. He hoped that all would agree with the resolution.

The resolution was then put from the chair, and carried unanimously.

Mr. Camplin, in proposing the third resolution, which had been put into his hand since he entered the room, would only detain the meeting to call their attention to the fact that the committee had hitherto had considerable trouble, and that they had ever acquitted themselves in such a manner as to deserve the most unbounded confidence from the members of the Institute. He then read the resolution.

Resolution 3.—"That the trustees, with the treasurers and the other members of the provisional committee, appointed at the Hanover-square Rooms on the 12th day of August last, be a special committee to conduct the election of the council; that they be requested to prepare and submit a list of members whom they deem most eligible to constitute the first council for the suffrages of every member of the Institute, with a distinct intimation that every member is at liberty to substitute any other names in his polling paper which he may deem expedient, and that the polling papers be returned on or before the 31st of October next."

Mr. Hood seconded the resolution, which, he said, had his most cordial approbation.

The resolution was put, and carried unanimously.

Mr. Bowling, in moving the fourth resolution, said that the meeting had hitherto been employed in appointing treasurers and trustees, but had not as yet provided for putting anything into their hands to take care of. He was unwilling to permit any treasurer to be obliged to advance to the association. He had heard gentlemen speak of the sinews of war, but he felt convinced that the war would be of only a moral character; he felt the more certain of this from seeing the perfect unanimity which had prevailed at all their meetings, as well as in all the councils of the committee of their association. He considered that the cause of medical reform had made much progress, and especially since the change in the Administration. The Institute had now friends in the Administration, and he felt they would not be treated with the coquetry to which they had hitherto been subjected. He could only recommend to the members of the Institute, that they should act so as to enable the council to enforce their position. He then read the resolution as follows:—

Resolution 4.—"That the annual contribution by the members of the Institute be fixed at one guinea, payable in advance, the payments to date from the 1st day of August in each year; and that no member be entitled to vote for the council without having paid his subscription."

Mr. Sutton, in seconding the resolution, had only one observation to make—it was, that as the subscription was so small, he felt convinced all would be prompt in their payment.

The resolution was then put from the chair, and carried unanimously.

Mr. Bonney said that the resolution which had been confided to him put the keystone to the formation of the Institute. It had been arranged that polling papers should be sent out, and it only remained for them to consider the time necessary, after the return of those papers, before an announcement could be made concerning the members of the council of the new Institute. The time suggested in the resolution which he would read was ten days.

Resolution 5.—"That the special committee for conducting the election be requested to advertise the result of the election within ten days after the date specified for the return of the polling papers, with a list of the officers of the National Institute, and to call a meeting of the council at as early a day as possible."

It was of the utmost importance that the members should be careful in expressing their approbation or disapprobation of different gentlemen as members of the council of the Institute. He hoped that their body would be the reverse of the existing colleges; he hoped that their council would, unlike those of the existing colleges, prove an honour to their institution.

Mr. Norton seconded the resolution, which was put, and carried unanimously.

Mr. Clifton thought the resolution he held in his hand, and which he would read to the meeting, one of the most important of the evening; it was to charge the council about to be appointed with one of their most important duties.

Resolution 6.—"That it be the duty of the first council to proceed with the enrolment; and, after the appointment of the necessary stipendiary officers, to draw up a code of by-laws, and to submit them to a future general meeting of the members of the Institute for approval; and to carry out the objects of the National Institute and of the National Association, as agreed upon at the public meeting, held at the Hanover-square Rooms, on the 17th of April, 1846, and recorded in the transactions bearing date the 1st of May, 1846."

He had no hesitation in saying, that from the manner in which the first council carry out their important duties would depend much of the success of the institution they were met to form and to concentrate. It had been a matter of much regret to him that for years general practitioners had not met with the consideration to which their education and attainments entitled them. He thought, probably, that if they had been less fitted for their position, they would have been better treated by the bodies who have arrogated to themselves an extended education and a higher position, or greater skill. For the future, general practitioners would look to their own Institute for their *status*. He believed the Institute would grow, under careful management, to be the highest in the kingdom; but, at the same time, he must warn the members not to expect too much at once. He believed the wisest course the council could take would be, at first to feel their way by degrees and carefully; but he knew that, from the unanimity which had always prevailed in their councils, the foundation they had laid would redound to the credit of the profession throughout the kingdom. By the resolution the gentlemen present would perceive that the council would be charged with the preparation of by-laws, to be submitted at a future meeting for the approval of the members.

Mr. Fuller, in seconding the resolution, said that individual members must not be contented with putting their own shoulders to the wheel. They must also endeavour to induce their medical friends to come forward to join the Institute.

Resolution put, and carried unanimously.

Mr. Joseph approved highly of every resolution which had been proposed that evening; he concurred too in the remark, that the present Government was much more likely to assist in carrying out the views of the mass of the profession than the former one. A committee had been formed to carry out the election of members of the council of the Institute. He wished to know how that election was to be decided, and how and by whom the scrutiny was to be conducted?

Mr. Bird said he thought there could be no difficulty in adopting a step which would be quite satis-

factory to the members. He suggested that the gentlemen present should appoint the scrutineers. He thought the committee were not called upon at that stage of the proceedings to explain more fully than had been done already the plan on which they proposed to conduct the election; but he thought that, if the members of the Institute had sufficient confidence in their committee to allow them to send out balloting papers, they would also have sufficient confidence to allow them to make public the result of the election. Mr. Bird then suggested that Mr. Joseph should propose three gentlemen to act as scrutineers.

Mr. Joseph then proposed a resolution to the effect that three scrutineers should be appointed.

Mr. Dermott, as an old reformer, begged to second the resolution.

Mr. Dowling said that, perhaps, it would be satisfactory to the meeting to know that the matter had been already considered by the committee, but that that body had thought it better to leave it to the members at the meeting to make any proposition on the subject. He would call on Mr. Joseph to name three scrutineers at once.

Mr. Bonney suggested that the gentlemen named should all be present at the meeting, in order that their consent might be obtained.

Mr. Brown suggested that the mover and seconder should form two and agree on a third.

Mr. Joseph would be happy to act, and would name as a third Mr. Robins.

Mr. Dermott regretted, that from the duties which would devolve on him at the commencement of the session, it would be impossible for him to give as much time to the scrutiny as it would require. Mr. Copley would act in Mr. Dermott's place.

Mr. Joseph, Mr. Robins, and Mr. Copley were then appointed scrutineers.

After a vote of thanks to the President, and the expression of the gratitude of the members of the Institute to the late Honorary Secretaries, Messrs. Bird and Ancell, which the latter gentleman acknowledged with much feeling, the meeting separated.

The utmost good feeling and harmony prevailed throughout the proceedings, and we noticed at the close of the meeting, that numerous gentlemen came forward and tendered their subscriptions.

TREATMENT OF FRACTURES OF THE CLAVICLE.

To Sir WM. BURNETT, M.D., K.C.H., &c.

SIR,—In conformity with your wish for me to report upon the new apparatus for fractured clavicle* of James Ellis, Esq., surgeon of her Majesty's navy, when an opportunity presented for testing its efficiency, I beg now to say that such an opportunity has occurred by a case from her Majesty's steam vessel Ardent, sent hither for cure on 16th of May last, and that it has succeeded perfectly, the union of the bone presenting not the slightest degree of irregularity.

Upon his admission there was the usual deformity, on which the common bandage and compression applied on board had produced no perceptible effect in retaining the fractured surfaces in apposition. Upon the application of Mr. Ellis's apparatus, I ordered the patient to bed, on account of the frequent carelessness of soldiers and sailors when allowed to walk about, even in the ward. On the 9th of May I permitted him to rise, and, in proof of my previous precaution not being unnecessary, found on the following morning the ends of the bone riding about as badly as at first. He was again ordered to bed, and kept there for something more than a fortnight, when the apparatus was removed, the union being firm, and having been so many days before; but, from what had previously happened, I deemed it proper to be more careful than could be necessary with a more considerate class of patients.

From close observation of this case, I am induced to think most favourably of the invention; and when we consider the frequent slur thrown upon surgical skill, for irregular union in fractures of this bone, and the particular necessity for guarding against its occurrence in women, whose dress so much more displays any deformity from such an accident, I think its use may be safely recommended to the profession. Confinement to bed for patients in civil life is by no means necessary: moderate care, a loose dress, and quiet ride for the first fortnight, seem to be all that is required. I have the honour to be, Sir,

Your most obedient servant,
JAMES PRIOR,
Deputy Inspector of Hospitals.

Royal Marine Hospital, Woolwich, July 6.

* A woodcut representing this apparatus—a useful modification of Desault's principle—will be found in a former number of the present volume.

GOSSIP OF THE WEEK.

MORTALITY ON BOARD AN EMIGRANT SHIP.—The following melancholy intelligence has been received at Lloyd's:—"Quebec, August 6.—The barque *Elizabeth and Sarah Simpson*, bound from Killala, with passengers, has arrived off the Basque Islands, and has reported a great number of the passengers, as well as the commander, dead, a contagious fever having broken out on board about a week or ten days after the ship quitted Killala. There were sixteen other cases of fever, said to have been brought on by bad water and the filthy state of the vessel." The *Quebec Mercury* of the 8th of August confirms the above. It states that the vessel had been eight weeks on her passage from Killala, that forty-two had died on the passage, and that the captain and two more passengers had expired since her arrival at Basque Islands.

ON THE TREATMENT OF OLD VENEREAL ULCERS.—The treatment adopted by M. Velpeau in these cases is simply to touch the purulent surfaces very carefully with the acid nitrate of mercury, which, he says, appears to act as a specific, both as a caustic and as a mercurial compound. He has tried other caustics, but has not found them to act with the same degree of efficacy against this affection, and is, therefore, of opinion that we ought not to hesitate to employ this treatment wherever we meet with indolent, excavated ulcers with equivocal characters, even when the previous existence of syphilis has not been detected—ulcers of this description being, according to him, almost always cured by it. He relates the case of a man who had thirty ulcers, of all sizes, and who had been under treatment for eighteen months without any amelioration. These ulcers were excavated, of a dirty grey colour, and had all the characters of venereal sores, they were merely touched once with the caustic, and in twenty days nineteen-twentieths of them were healed. "It is true, however," says M. Velpeau, "that the protoiodide of mercury was given internally (which ought to be done), in conjunction with a saline mixture and a few baths, but nevertheless it was a very satisfactory result."

ANTIDOTE TO PRUSSIC ACID.—M. Larocque has been lately engaged in performing some experiments with a view of testing the practical efficacy of the mixed oxides of iron as an antidote for prussic acid. He has arrived at the following conclusions:—1. That the alleged antidote has no effect whatever when prussic acid has been taken in the anhydrous state. The rapidity with which this poison causes death is too great. 2. The same objection applies to its use when the anhydrous acid has been swallowed diluted with its volume of water. 3. That good effects may follow its use when it is employed at the commencement of symptoms, and the dose of the medicinal acid is about from sixteen to twenty-five grains. 4. That when the medicinal acid is diluted with a large quantity of water, there is in most cases great hope of recovery. 5. That chlorine increases the efficacy of the antidote.—*Gaz. Med de Paris.*

"The science of magnetism is scarcely in its cradle, if one may call by the name of science a theory without principles or laws, a bunch of physics, the objects of which escape the senses, which communicates itself, and operates in a marvellous and inconceivable manner, and in which all is miraculous; or rather, if one may call 'science' a collection of facts, of observations without end and without connection; a tissue of erroneous opinions and ridiculous hypotheses." The above is the opinion on magnetism contained in a memoir on medical electricity, to which a prize was decreed by the Academy of Rouen. This memoir was published in Paris in 1785; and who was its author? Marat! In reading this work, who would believe that eight years afterwards a learned physician would lay aside his mask of man, to show only the demagogue, the wild beast wallowing in blood and mire?—*Gazette Medicale de Paris.*

HOSPITAL STAFF.—William Donneland Marchant, gent., to be Assist.-Surg. to the Forces.

The cholera still rages at Scinde. On the 15th, 16th, and 17th days of June, 255 Europeans died of the epidemic.

The disease among cattle has broken out afresh in Poland to such an extent that the exportation of cattle has been prohibited.

The accounts from the different parts of France all agree in stating that the reports respecting the potato disease have been greatly exaggerated. In a few localities signs of the disease which attacked the crop last year have reappeared; but it is ascertained that the disease has only attacked certain species of the vegetable.

M. Kuss has been recently elected by *concours*, after a severe contest, Professor of Physiology at the University of Strasbourg. MM. Serive, Lerchoullet, Strohl, and Michel were also candidates.

The Sultan is at present travelling, and wherever he goes he has all the children, both Christians and Turks, vaccinated.

OBITUARY.—We regret to have to record the death of Percy Earl, Esq., the naturalist, who was drowned in the Torres Straits, in the month of May last. Suddenly, Mr. James Knox, many years resident medical officer of the Barnstaple Infirmary. On Thursday, the 27th ult., aged 21, Baker-street, Portman-square, Thomas Jackson, Esq., late Surgeon of the 14th Regiment, after a long and protracted illness, aged 80.—At Port of Spain, Island of Trinidad, West Indies, 16th ultimo, Stephen L. Carmichael, M.D.—At Bridge of Allan, 21st ultimo, Mr. Alexander Miller, of 32, Buccleuch-place, Edinburgh, Fellow of the Royal College of Surgeons.

MORTALITY TABLE.

For the Week ending Saturday, Sept. 12, 1846.

Causes of Death.	Total.	5 Sum-	Average of 5 years.
ALL CAUSES	884	898	968
SPECIFIED CAUSES	881	892	961
Zymotic (or Epidemic, Endemic, and Contagious) Diseases	209	201	188

No. 364. **SUMMARY.** SEPT. 19

PROGRESS OF MEDICAL SCIENCE,

INCLUDING CHEMISTRY AND PHARMACY.

France.

ACADEMY OF SCIENCES.

Meeting of Sept. 7; M. MATHIEU in the Chair.

EXPERIMENTAL PHYSIOLOGY.—THE HUMAN VOICE, BY DR. BLANDET.—Muller endeavoured to ascertain the exact mechanism of the human voice by experiments conducted on the following plan:—The arytenoid cartilages being fixed upon a board, the tension or relaxation of the vocal chords was obtained by an increase or a diminution of the strength of a stream of air blown through the larynx; but the experimentalist deprived the instrument of its natural vibrations by the inflexible nature of its support. Dr. Blandet proceeds upon quite a different principle. Rejecting all comparison of the human larynx, with a bird-call, a reed, or any instrument whatever, he attempts to supply the absence of muscular contractions with another power, giving in the first place a solid fulcrum to the thyroid cartilage. To replace the action of the sterno-thyroideus and hyoideus muscles, he obtains by pressure on the basis of the arytenoid cartilages an effect similar to that occasioned during life by contraction of the thyro-arytenoideus muscle. A stream of air forced at the same time through the glottis gives rise to acute sounds, the vocal chords being, by this process, permitted to vibrate only in their anterior portion. The action of the crico-arytenoideus lateralis, by which the glottis is partly relaxed, can readily be imitated by raising with the finger the inferior margin of the arytenoid cartilage: in this state medium tones can be produced; lower tones are obtained when the crico-thyroideus drags forward the thyroid cartilage—a condition easily established by pressure with a finger; the lowest notes result from imitation with the hand, of the action of the crico-arytenoideus posticus. It is interesting to remark that the sounds issuing from the larynx in the dead subject are stronger and more natural during artificial inspiration than during expiration; the peculiar sound of the voice of the deceased is perfectly reproduced.

DISEASES SPECIAL TO PAPER-STAINERS, BY A. CHEVALLIER, Member of the Academy of Medicine, &c.—Workmen engaged in the preparation of arsenite of copper, and paper-stainers who use it in their trade, are exposed, from the action of the poison, to a papular eruption of the skin; to a remarkable anasarca of the face, bust, and scrotum; and to severe abdominal colic. M. Chevallier has attentively studied these symptoms, which are, it is true, not very common, on account of the very small number of persons occupied in that branch of the trade, and recommends the adoption of the following measures as calculated to preserve the men from the effects of the poison:—1st, large and well-ventilated rooms; 2nd, gloves for the protection of the hands during solution of the arsenious acid; 3rd, frequent lotions and sulphurous baths; 4th, the internal administration of the sesqui-oxide of iron.

THE ERGOT OF RYE—DR. PAROLLA.—Dr. Wright showed, in 1837, that the ethereal oil of ergot, at the dose of thirty drops, is as powerful as ʒj. of the powdered secale cornutum: in this Dr. Parolla fully agrees with Dr. Wright; but from the oil he has separated, by the assistance of alcohol, a resin which he conceives to be the real active principle of the drug, and which enjoys a powerfully-sedative action. According to the author, this resin might replace most antiphlogistic measures; at doses of six to eight grains daily, he has found it efficient in pneumonia, typhus, and uterine hemorrhage. And so enthusiastic is Dr. Parolla in the cause of the resin that he conceives it to be capable of curing pulmonary consumption; a case of *complete cure*, he brought before the Scientific Congress at Florence, *with the anatomical preparation* · a proof of a rather unsatisfactory sort of recovery. Dr. Parolla states that the ergot is not a cryptogamic formation, but a morbid secretion of the diseased grain.

ORGANIC CHEMISTRY.—M. Payen asserted some years since, that fecula contains an essential oil, to which is due its special odour, and which can be extracted by the action of pure spirit. Many chemists, and among others Professor Liebig, attributed the formation of this oil to alcoholic fermentation; Liebig further considered the presence of a fibrinous, putrescible substance in the pulp necessary to the special fermentation which generates the oil, and added that when, instead of acting on boiled tubers, fecula was saccharified by the action of sulphuric acid, the essential oil was no longer produced. M. Payen having repeated this experiment, and again obtained the oil, concludes that his former view was correct, and that the objection made to his statements must in consequence fall to the ground. He thinks that, by the same method of operation which he has employed, the peculiar aroma of wines, spirits, &c., can also be separated.

STRUCTURE OF THE LIVER.—An important anatomical memoir was read on this subject by Dr. N. Guillot. The microscopic researches of that anatomist fully confirm Mr. Kiernan's views. Mr. Kiernan had not succeeded in seeing the anastomosis of the smallest biliary divisions, and his injections were always made on the liver of the cat or pig. Dr. Guillot has successfully injected the human liver in its healthy and in its diseased states, and in numerous anatomical preparations and designs, clearly demonstrates the intimate structure of the viscus. We will in our next communication forward to the readers of the *Medical Times* an analysis of his memoir.

ACADEMY OF MEDICINE.

Meeting of Sept. 8; M. ROCHE in the Chair.

M. Huguier read a paper on the diseases of the sebaceous follicles of the organs of generation in women. The most striking part of this memoir referred to hypertrophy of the follicles, which, becoming inverted in consequence of the progress of acute or chronic inflammation, present the appearance of the syphilitic mucous tubercle, for which they are often mistaken. This affection can be removed only by a surgical operation; M. Huguier's researches led him to inquire more closely into the structure of these organs, and to find that sebaceous glands are not merely bags with a narrow orifice, but perfect glandular bodies lying in the structure of the dermis, on the surface of which they terminate by an excretory duct.

On a former occasion (see *Medical Times*, vol. xiii., p. 2) Dr. Huguier presented anatomical and physiological details on the vagino-vulvular glands. Having now completed his researches, he laid before the Academy an account of its diseases. These organs are frequently the seat of acute inflammation, the consequence of venereal indulgence; abscesses of the glands have been generally confounded with phlegmonous inflammations, pre-recto-vulvular and stercoro-vulvular abscess; from the latter they can be readily distinguished by the dark colour of the pus, its fetid odour, the possibility of the suppuration ulcerating the rectum, and the formation of a cylindrical cord by which the cicatrix of the labia is attached to the intestine after the cure.

HYSTERIA, BY DR. GENDRIN, Physician of the Hôpital de la Pitié.—In a letter addressed to the President of the Academy, M. Gendrin brings forward the following opinions on the nature, symptoms, and treatment of hysteria:—1. Hysteria does not merely consist in intermittent spasmodic attacks: it is a continuous malady which presents always characteristic symptoms in the intervals of the convulsive fits. 2. In all cases, without exception, from the beginning of the disorder to its termination, a general or partial loss of sensation may be observed; when the disease is mild in its form, anesthesia occupies only limited regions of the skin; when it is severe, on the contrary, it occupies the entire cutaneous surface, and the mucous membranes accessible to our means of exploration, such as the conjunctiva, the pituitary surface, the buccal mucous membrane, the rectum, urethra, vagina, and urinary bladder. It is not very uncommon to meet with this anesthesia in the organs of special sensation, and in deep-seated parts. Some patients lose the consciousness of the acts of locomotion and of the position of their limbs. 3. The degrees of anesthesia and of the violence of the fits do not bear any proportion to each other. 4. Most patients thus affected present in various regions, at least during the presence of the convulsive fits, a degree of pain, which is in general the proximate cause of the attack, and which furnishes the physician with a valuable practical indication. 5. In hysteria, paralysis, with flaccidity or contraction of the affected part, is a very frequent symptom which has often caused error of diagnosis, and which may last without peril for months, even when it occupies the bladder, rectum, or limbs. 6. It is a mistake to consider the sensation of the globus hystericus and asthma as phenomena constantly attendant upon hysteria. Two other forms of attack are very common or alternate with dyspnœa; Dr. Gendrin refers to paroxysms of ecstasy or mania. 7. All the apparently

marvellous peculiarities of animal magnetism may be spontaneously produced in hysteria. Thus, the insensibility which permits operations to be performed without pain exists in all the forms of the disease. In ecstatic hysteria it is observed in its highest degree. 8. The anomalies of enervation in hysterical subjects show themselves in the immediate action of medicines. Thus, patients who have no increased excitement of the digestive organs can take 12, 15, or 20 grains of opium without experiencing any narcotic results. If the stomach is in an irritated condition, the opium is rejected and no narcotism is observed. A few cases, not sufficiently numerous, however, to permit Dr. Gendrin to draw from them any positive conclusions, lead him to believe that in hysteria large doses of hyosciamus and of belladonna may be exhibited with impunity. 9. The most efficient drug in the treatment of hysteria is opium. The doses should be at first 6 grains daily, and be carried to 10 or 15 grains in the 24 hours. When a narcotic effect has been obtained, all the hysterical symptoms are observed to decrease, and the medicine should undergo a daily diminution. 10. Sulphuric ether, in doses of ℥ss., ʒvj., or ℥j. daily, is also very useful; but its beneficial action is not produced unless the patient takes these enormous quantities; no accident ever results from them.

A New Plan of Treatment of Urinary Calculi. By Dr. Dumesnil, late Interne of Hospitals, &c.

The extremely painful alternative of performing lithotomy, or of crushing the stone with lithotritic instruments, has, no doubt, long since suggested to many surgeons the idea of destroying calculus by the use of solvents; but the problem is so complex, the difficulties of execution so great, that all hope of obtaining that desirable result has been in some measure abandoned. The variable composition of calculi, the danger of placing irritating substances in contact with the lining membrane of the bladder, and the inanity of the researches previously made to attain the object, are fully set forth in Dr. Prout's excellent work ("Stomach and Urinary Diseases," p. 457). Dr. Dumesnil has not, however, been deterred by the failure of his predecessors, and in a communication replete with interest, which he has lately forwarded to the Academy of Medicine, proposes a new mode of treatment, of which we will endeavour to give a rapid description.

For the sake of lucidity, we may divide into three sections the memoir before us:—1. Composition of calculi; diagnosis of their nature. 2. Action of solvents upon them. 3. Possibility of dissolving the urinary concretions in the bladder without injury to its parietes.

Section 1.—For practical purposes calculi may be divided into three varieties,—lithic, phosphatic, and oxalic,—the two latter being most usually combined with alkalis; the former, on the contrary, remaining very frequently in its pure acid condition; hence the conclusion may be immediately drawn, that one solvent cannot possibly answer in all cases, but, as Dr. Prout very justly remarks, the substances which might act upon one set of concretions in such a manner as to disaggregate them, would, in all probability, have a contrary effect upon another series. It is, therefore, of indispensable necessity to recognise the *nature* of the stone before any operation be instituted; for this purpose the analysis of the patient's urine furnishes only very uncertain data; nor does its changeable appearance give the surgeon anything like positive information. Dr. Dumesnil seeks for the required knowledge by the application of Fourcroy's method, with the assistance of an instrument of which we will endeavour to give a description in the 3rd section. He places very dilated sulphuric acid in contact with the stone, and forms his opinion of the nature of the calculus by the examination of the liquid which returns: if it contain sulphate of lime, the calculus is a phosphate or an oxalate, and will yield to acids; if it contain no lime, it is most probably formed of uric acid, and can be dissolved only by alkalis. This plan of diagnosis does not, of course, exclude the study of functional disorder, nor authorize the surgeon to neglect the information to be gathered from the use of the catheter. The great object is to introduce without danger the acid solution, and that object Dr. Dumesnil seems to have attained.

Section 2.—When a fragment of phosphate of lime is placed in contact with muriatic or nitric acid, it is immediately dissolved; but a *calculus* of phosphate is not disaggregated by the action of these acids, because they have no power on the organic cement by which the elements of the stone are connected. This cement is readily dissolved in sulphuric acid, which also enjoys the advantage of forming soluble compounds with ammonia and magnesia. Muriatic acid, however, also destroys very rapidly the organic part of the concretion, and M. Dumesnil employs them both in equal quantities,—of each half a drachm to three ounces of distilled water at 40°. The agitation of the fluid adds considerably to its power.

Alkaline solutions are to lithic calculi what acids are to oxalates and phosphates. Gay-Lussac and Pelouze, Scheele and Prout, have given to alkaline carbonates a fair trial, and have recognised their complete inefficacy. Borax has appeared to Dr. Dumesnil to be a little more powerful; but a solution of two per cent. of potass in distilled water is the fluid which he has found most rapidly active: at 20° the alkaline solution dissolves the stone as well and as speedily as at 40°—a circumstance which may be, perhaps, explained by the ready formation of carbonates under the influence of heat. From his numerous experiments, Dr. Dumesnil thinks himself authorized to conclude that in seven or eight hours the largest phosphatic calculi may, by this method, be dissolved in the bladder; he is inclined to say the same of uric acid concretions; but oxalate of lime communicates to the stones of the other form a degree of density which would render a longer period necessary for their complete destruction.

Section 3.—The membrane which M. Dumesnil employs for the purpose of isolating the stone in the bladder consists of a piece of intestine, greased on both its surfaces to prevent exudation and exosmosis of the solvents through its parietes. The bag is introduced by means of a straight catheter, very slightly bent at its extremity, and is opened and closed with a steel spring. In manipulations repeated numberless times on the dead subject, the calculus was easily seized and thrown out of the sac; through the tube of the catheter the solvents were injected, and a continuous double stream was established. By numerous experiments the author proves that the acid or alkaline fluids, diluted, cannot by any means perforate the sac so as to come into contact with the walls of the bladder. The injection is continued for an hour and a half or two hours, according to the condition of the patient, and is repeated until the complete destruction of the stone has been obtained, or until the diminution of its size permits its extraction through the urethra. Such is the new method proposed by Dr. Dumesnil; and when it is recollected that lithotomy is one of the severest operations practised on the human frame,—that lithotrity is applicable only to chosen cases, in which the bladder is healthy, the stone small and friable, and that even with these favourable circumstances it is always attended with much pain, and not unfrequently with considerable danger,—it will be readily admitted that all efforts directed towards the laudable end of rendering these operations unnecessary are deserving of encouragement. The method proposed by Dr. Dumesnil, which he calls lithomenia (from λιθος, a stone, and υμην, a membrane), is undoubtedly imperfect in many of its details; but it is, to say the least, an ingenious application, and will, we trust, induce others to turn their attention towards the same subject.

Cæsarean Operation.—("Gazette Med. de Strasbourg.")—Dr. Sclater was called on the 15th of January, 1846, to the assistance of a deformed woman, aged 31, who had already been twelve hours in labour. The patient was primiparous, and not more than 1 m. 30c. (4 feet) in height. The pelvis was extremely oblique, the sacrum depressed, and the right crista ilii one inch higher than the corresponding part on the left side; the uterus was, besides, in a marked state of anteversion. On examination per vaginam, the ischia were found to be separated from each other only by an interval of four or five centimètres; and this was also the extent of the antero-posterior diameter of the brim. The waters had been discharged; the orifice was turned backwards, and dilated to the size of a crown piece. The pains succeeded each other at short intervals. Dr. Steinbrenner having been called in by Dr. Sclater, the operation of hysterotomy was agreed upon, and an incision fifteen inches in length was performed on the linea alba, one half above, the other half below, the umbilicus, and a second section having divided the peritoneum and aponeurosis, the uterus was cautiously incised and the placenta uncovered. The index and medius fingers of the left hand were then introduced, and the placenta detached in its superior part. The wound of the uterus was increased to the extent of the incision of the skin; the feet of the child were seized, and delivery performed without any further obstacle. Between the extraction of the infant and the removal of the placenta, a large quantity of blood was lost, but the hemorrhage was suddenly arrested by delivery, and, the uterus returning rapidly to its natural size, the greatest difficulty was experienced to maintain the intestines in the abdominal cavity. The wound was closed with six quilled sutures. The child was alive, well formed, and strong; one application of leeches on the abdomen was necessary, but the recovery was complete six weeks after the operation.

Digestion in 1846.—(From the "Journal de Médecine.")—At last the phenomena of digestion are enlightened: digestion is no more to be considered a simple but a complex function. There are as many digestions as organs. First, the stomach, by which animal food is dissolved; it is in carnivorous animals almost the only intestine, and they require no other; their digestion is gastric; it is intestinal in herbivorous tribes. After the incisors and cuspidati come the molares: in the same manner after the carnivorous intestine we find the intestines which digest grains and vegetables masticated by the molares. In the small intestine feculent substances are absorbed and saccharified—a fact proved by a simple experiment; fecula taken in the stomach immediately above the pylorus will become blue when placed in contact with iodine, and will, on the contrary, not change colour after its passage through the pyloric orifice. It is this, the principal phenomenon of digestion in the duodenum, which has led to the discovery of the saccharifying power of the pancreatic secretion. Hence not only a change in the theory of digestion, but in the pathology of diabetes; we can no longer admit that the kidneys secrete sugar, but that they allow the passage of the saccharine matter contained in the blood.

All these discoveries are in themselves important scientific acquisitions; but their importance is doubled when their practical consequences are reflected upon. The whole history of gastralgia, *rudis indigestaque moles*, must begin anew. No theories can be compared to the recent discovery of the following facts. Eat meat, the urine becomes acid; eat vegetables, it immediately becomes alkaline.

The gastric juice is a powerful acid, which readily gives birth by fermentation to gaseous products. In dyspepsia it is therefore a mistaken practice to recommend the use of alkaline salts, by which the digestion of animal food is retarded. The corrosive nature of the fluid accounts for gastric pain, pyrosis, &c., most probably the result of its contact with dry portions of the mucous membranes. By fermentation in the stomach, foul breath and flatulency will be produced; alkaline medicines will be of no avail, but mild laxatives are fully indicated. The digestive power of the gastric juice varies with its heat; below 10 deg. and above 55 deg., that power diminishes, and is completely lost beyond 50 deg. It is therefore not proper to eat very hot substances.

The stomach being the organ in which animal food is dissolved, meat should not be given in gastric affections; whereas feculent substances, digested in the jejunum, can be safely permitted.

Dan. M'Carthy, D.M.P.

PRACTICAL REMARKS ON FISSURES OF THE ANUS, AND THEIR TREATMENT.—M. Thiry has published in the "Journal of Medicine, Surgery, and Pharmacology of Brussels," a paper on the above subject. The following are the chief facts which the author has brought forward:—Uncomplicated fissures of the anus are kept up by a diminution of the contractility of the muscular fibres of the middle portion of the rectum which becomes excessively dilated, the fibres not having sufficient contractile power to expel the fæces, and to overcome the resistance opposed to their passage by a spasmodic contraction of the sphincter. This spasmodic contraction does not, therefore, according to M. Thiry, deserve the consideration which has been hitherto paid to it. Means should not be applied to remedy this contraction unless it be of extreme activity, in which case it should be treated as a complication. Injections of an infusion of ratany appear, in the opinion of M. Thiry, to be the most prompt and efficacious remedy in the treatment of these fissures. As the injections cannot act unless the rectum be empty, and the fæces do not habitually distend it, it is necessary to precede and accompany their use by the administration of gentle purgatives, emollients, and a severe regimen. Hip-baths, cold, and sedatives should be used, in order to relieve the pain, itching, and severe spasms which accompany fissures of the anus. If the fissure arise from any local or constitutional disease, of course such must be removed. Fissures of the anus seem so inherent in the constitutions of some patients as to be quite incurable; sometimes, too, they seem to be salutary emunctories, established by nature for the relief of congestion. Operations in cases of anal fissure should, according to M. Thiry, be entirely abandoned. If, however, any case should be met with, in which the operation should appear necessary, it should be done by the method of subcutaneous section; under such circumstances, however, the author insists that the operation relieves only a single symptom, and produces no effect on the origin of the disease; it is therefore necessary to assist it by other appropriate measures. Cauterization, dilatation, alteratives, and narcotics affect only one or more symptoms of the disease, and not its chief cause. These remedies are, therefore, simple adjuvants, which may indeed be used, but which must at the same time be combined with more active treatment. An apparatus, invented by M. Cazenave, of Bordeaux, may, when used in combination with the injections of infusion of ratany, previously recommended, be of some service, by its preventing the fæcal matters from coming in contact with the surface of the fissure.

ON THE WATERS OF BAREGES IN THE TREATMENT OF GOUT.—Dr. Koene has published, in the same journal, some remarks on the treatment of rheumatic and gouty affections which are worthy of our attention. After premising that rheumatic and gouty affections, and the different chronic diseases of the skin are "the result of the efforts which this principal emunctory makes to throw off acids from the system, in order to leave in the blood and other fluids a free alcali, especially soda, capable of holding fibrine, albumen, and proteine in solution, Dr. Koene goes on to say, that by saturating these acids, and introducing into the economy a solvent for the principles capable of nourishing the tissues, the system may be brought back into a state of health. The aluminate of soda, administered in baths, possesses considerable power in the treatment of gout; but, while being absorbed through the skin, the soda, in this remedy, leaves the aluminic acid, which, by obstructing the pores, at length opposes the absorption of the remedy, at the same time that it prevents cutaneous transpiration. Such of the sudorific medicaments as, from their affinity to oxygen, are at the same time capable of neutralizing the acids in the system, appear more fitted to fulfil the indications required. Such are the sulphuretted alkalies which possess the power of arresting, up to a certain point, the formation of the uric and phosphoric acids, of destroying the animalcules and cryptogamic vegetations which are so frequently met with, and of removing from the skin all that this organ eliminates from the blood. The most used of these sulphuretted alkalies is the trisulphuret of potass; but this compound excites considerable irritation of the skin, and is unable to yield to the constitution the required alkali; it also gives off a very disagreeable smell, and deposits, by the action of acids, more or less sulphur, which, like the alum before mentioned, must obstruct the pores, though perhaps in a less degree. This sulphur, indeed, is absorbed after a time; but the absorption itself is a source of annoyance to the patient, as it forms in the skin during the process of absorption, even a long time after the bath has been taken, hydro-sulphuric acid, the smell of which is very disagreeable. The proto-sulphuret of soda possesses only one of these inconveniences—it is that of disengaging hydro-sulphuric acid also, but this inconvenience may be avoided by mixing it with a solution of carbonate of soda, which produces a bicarbonate, water, and sulphur.

ON A VARIETY OF MALIGNANT PUSTULE NOT HITHERTO DESCRIBED IN NOSOLOGICAL CLASSIFICATIONS.—Dr. Van Swygenhoven reports in the same journal a case illustrative of a variety of malignant pustule which is never communicated, either directly or indirectly, to man by animals affected with it. The following are the principal characteristics he assigns to it:—Its attacks are much the same as those of the ordinary malignant pustule, from which it differs only in possessing less intensity. The form of the pustule is almost always oval, and seldom exceeds the size of a grain of maize. Sometimes, however, it inclines to a rounded form. The vesicle is always larger than the gangrenous point; the serosity is rarely of a reddish colour, generally white, slightly saline, and does not excoriate the neighbouring parts. This serosity, introduced into another animal by inoculation, does not produce any similar or analogous affection. The neighbouring parts redden, and become inflamed and swollen; the swelling increases, and much exceeds in size the point in which it first commenced, without being accompanied by phlyctenæ or crepitation. The gangrenous eschar does not increase, and does not extend deeply. The general symptoms are never severe, and seldom exceed a slight degree of irritation. A crucial incision with a lancet often cuts the disease short, but the actual cautery is injurious, and the application of caustics must be had recourse to only with great caution. A strict diet, and local and general bleeding, reduce the symptoms rapidly. At the expiration of three or four days the eschar is detached, and after this the cure proceeds rapidly.

The Nature, Causes, and Treatment of Mental Diseases.

By M. PINEL, M.D., Member of the Academy of Medicine, formerly Physician to the Bicêtre and Salpêtrière Asylums, Author of the "Traité Medico-Philosophique sur l'Aliénation Mentale," "Médicine Clinique," "Nosographie Philosophique," &c. &c. Translated, with Notes illustrative of some important Doctrines in Physiology, Phrenology, and Moral Education.

BY DR. COSTELLO,

Principal of Wyke House Asylum, Editor of the Cyclopædia of Practical Surgery, &c.

PARALYTIC CEREBRITIS.

From my own minute investigations into the nature of general paralysis, I think that four principal alterations characterize this disease—the acute inflammatory state, the chronic, the state of atrophy, and that of hypertrophy of the brain. Whether these alterations, which represent almost the entire acute pathological anatomy of the brain, can be distinguished from each other during life, or whether we can diagnosticate with such certainty as to enable us to apply the proper treatment to each, are questions which futurity must determine; for the present we have only to remark that in the general course of paralytic cerebritis we see that the symptoms are always the same, with the exception of some varieties inevitable in their commencement, progress, and violence, and which depend on the predisposition of each individual. I do not, however, doubt that we shall be able to distinguish the peculiar symptoms of inflammatory atrophy and inflammatory hypertrophy, these two alterations being too opposite not to depend on characteristic phenomena. But, in the absence of more precise data, we must hold to rational indications and the results of experience.

A most important point in general paralysis is to be alive to its earliest symptoms, if we have the good fortune to be consulted in time, and to act at once with as much energy and decision as if the disease was fully declared, it is at this period in reality that we can hope for success. I have stated that after repeated trials the curative method that I found to answer best was, the daily application for several months together of cupping-glasses to the nucha, abstracting not more than a tablespoonful of blood at a time; this with a scrupulous perseverance. Internally, I prescribe a light infusion of arnica rendered palatable with syrup of chicory. Regimen constitutes an essential part of this treatment; it should be nutritive and slightly tonic. A debilitating regimen, and especially bloodletting, will visibly accelerate the fatal progress.

When the disease is more advanced, the great point is hygienic care, and watching that excoriations are not allowed to spread, which they will do from the incontinence of urine, if not prevented. At this period the patient, no longer able to stand, is confined to bed or to a *chaise percée* for several hours in the day. The most grievous complications of this unfortunate situation arise from his inability to retain his excrements, which are passing off continually, and with the offensive smell of which the person and clothes become impregnated. To obviate this a leather couch has been employed, provided with a leather tube for the escape of the fæces and urine; but this soon becomes infected with the smell, while its use becomes an excuse for less care. The best thing is to have the means of changing the linen, the bed, and the posture as frequently as the patient's wants require, and by constantly persisting in this plan of management the sores are prevented, or healed, even in hospitals where such ample facilities do not exist as in private establishments. At this period the therapeutic treatment presents general indications only; the two most important are to obviate obstinate costiveness, or colliquative diarrhœa; constipation becomes the cause of general reaction. I have seen several cases where death, preceded by symptoms of tympanitis, was caused by an accumulation of hardened black fæces, and which could not be moved by the most powerful drastics. The evacuations should be kept in a solid state by a careful appropriation of food and medicine.

A careless and over-buttered cookery will often cause diarrhœa, and if it be allowed to proceed unchecked, the patient is reduced to a state of marasm in a week, and soon dies.

As regards the eschars that form about the sacrum, their dressing requires particular care. These sores, which are regarded as gangrenous, are supposed to require stimulant dressings, powdered bark, Goulard's ointment, and camphorated spirit of wine. Such treatment is improper: these sores are active, from the irritation caused by the patient's posture, his urine, and perhaps neglect. Emollients are therefore the best adapted to procure cicatrization. The constant change of position would of itself be sufficient to cause the sore to heal, but this cannot be done without in turn exposing the trochanters, knees, and elbows to excoriation. (a) I have seen at the Salpetrière a woman with general paralysis who presented a remarkable phenomenon in this respect, although still young, and with the appearance of *embonpoint*, she lapsed suddenly into the third and last stage of this disease, and wherever her skin was touched, even slightly, a gangrenous eschar formed the next day. She died promptly, as if struck with a general decomposition.

Delirium Tremens, which is scarcely more than a variety of the most common forms of general para-

(a) I have now a patient under my care who has used a water-bed for the last two years. She was placed on it at first for extensive sores, which have thus been cured.—TRANS.

lysis produced by the abuse of ardent spirits, when slight, is cured by regimen alone When more serious and chronic, it presents the symptoms of this disease, and requires, in addition to the means of treatment mentioned, the use of opiates under various forms and doses

Serous Congestions in the Brain—Œdema of the Brain—Œdema of the brain, with compression or infiltration of its tissue, is not an unfrequent complication of mania; it comes on suddenly in persons predisposed to lymphatic diseases, and gives rise to the series of symptoms already described under the head of acute stupor of the insane Its therapeutic treatment deserves attention

In this serous exhalation the general effect of which is to cause cerebral compression, the indication is obvious to disencumber the brain through the operation of diuretics and revulsives, and, as the direct effect of the compression is to suspend or benumb the nervous action of the brain, we may, in this case only administer diuretics and drastics in doses larger than usual, and the more so as they will act only in high doses I have administered fifteen drops of croton oil without procuring more than an ordinary evacuation The ordinary dose would prove inert, and the same may be said of irritants to the skin, the general insensibility being such as to require the most energetic irritants, and it is only when the patients recover in some degree that they begin to feel the pain of operations that had been practised on them weeks before, the sensibility and intellect then revive, and the pain of setons, moxas, or blisters becomes perceptible

Bloodletting increases the symptoms, doubtless, by favouring an increased serous exhalation, cold baths, and the applications of cold to the head, have not seemed to me to produce any good effect, but the *bain de surprise* might be employed effectively, as acting doubly, on the body as well as the mind, and producing a salutary commotion But as the disease is seldom dangerous, and as it consists merely in a brief suspension of the intellectual, sensitive, and motory functions, and as its duration may be abridged by diuretics and revulsives, it will be most prudent to limit our interference to these means

Acute and Chronic Hydrocephalus—As acute hydrocephalus, especially in very young children, presents in its progress all the symptoms of meningitis and encephalitis, of which it is often only the final one, it is necessary to employ all the means already recommended for the treatment of inflammatory congestion of the brain As regards the effusion itself, the treatment consists, like that of œdema, in the use of revulsives applied to the skin and derivatives to the intestinal canal, together with the exhibition of the most active diuretics Some caution may be necessary as regards purgatives in children, as in most of the acute cerebral affections there is an inflammatory complication of the gastro intestinal organs Tartar emetic given *en lavage*, or, according to the counter-stimulant plan of Rasori, if there be no disorder of the bowels may procure the absorption of the effusion, this was Laennec's plan Among the various diuretics the different preparations of squill and powder of digitalis, alone or in combination with calomel, may be advantageously employed. Local bleeding may be advisable when we have congestion of the brain or when a habitual hemorrhage has been suppressed If there should be any counter indication to their use internally, the strongest diuretics may be employed endermically. Some recommend dry aromatic fomentations, or plasters of soap and camphor, applied to the head In former times and even now, many recommend incisions caustics, nay, the actual cautery, the slow or prompt evacuation by means of an operation has also been recommended, but experience has shown that death has soon followed the sudden removal of the fluid

In chronic hydrocephalus, when all medicinal means have failed the perforation of the cranium has been frequently undertaken by anatomists and surgeons of eminence It is demonstrated that this evacuation causes death while, on the other and, the presence of the fluid becomes a habitual state, dangerous no doubt, but still compatible with the patient's continuing to live, and our art does not allow us to tamper knowingly with the lives of others. Gœlis's treatment is much extolled, although very complicated It consists of the use of calomel internally and of mercurial ointment externally The patient to wear a woollen cap, to use alkaline baths, and to open an issue, to be kept suppurating with carbonized antimonial ointment Inflammatory symptoms are combated with leeches, and the strength is kept up by combining the diuretics with tonics. According to this physician, calomel is the chief remedy, alone or in combination, it is proper in the first and second period, and may be given in the third as a palliative.

Irritant baths should be used, more particularly in chronic hydrocephalus, as their general action excites uniformly the organic activity over the entire surface of the body, and thus effects extensive revulsion The patient should live a good deal exposed to free air, but without being exposed too much to the sun

The preventive treatment of chronic hydrocephalus would be doubtless the best, if we could detect it in its incipient state but usually the disease exists before we are consulted We should, on the score of prevention—if we find cutaneous eruptions in children, oozings from the head, or the habitual formation of scales or crusts on the scalp—we should be cautious about meddling with them in any other way than by the administration internally of the mildest means and these only occasionally The intellectual education is also another important point of the preventive treatment Precocious children of lively reasoning, intellectual powers, are often urged forward by the vanity of parents or the speculation of their tutors this excitement, too great for the strength of the brain, and coinciding with the progress of development still going on in this organ, produces sanguineous or serous congestions that prove fatal and thus nips in the bud the most promising flower

Epilepsy—The principal hygienic indications, consisting of due surveillance and a proper shape of couch, have been already mentioned We have now to see, amongst the multitude of remedies that have been recommended in this disease, which are most worthy to be relied on

We may here repeat that it is only at the commencement of the epilepsy that treatment has any favourable chances of success, and we must act at the period as against an intermittent affection of the cerebral tissue Revulsives and derivatives, employed unsparingly, may determine a general shock, which may avert the disease When the epilepsy is confirmed, and the affection has deeply attacked the cerebral pulp art possesses but little resource, and we are forced to rely on empirical means only

In incurable epilepsy we have one certain fact, which is, that when the attacks are neither violent nor frequent the use of a new remedy always procures amendment, but it is of short duration I have found the belladonna to be one of the most effectual medicines of this kind, under its influence I have certainly seen the attacks become milder and fewer A cure has even been supposed to have taken place, when, after a considerable lapse of time, the disease has returned It should be given in the dose of one-fourth of a grain at first, increasing it successively to two or three grains It is often necessary to suspend it, owing to giddiness, illusions of sight, and vertigo We can readily imagine the effect of belladonna if we admit that the seat of epilepsy has anything to do with the optic tracts, but what can its action be, if the disease depend on an organic deformation in the nervous pulp, or a local induration?

Indigo, that has been so much extolled, has been tried at the Saltpetrière, without producing any other effect than dyeing the nails of the patients blue Carbonic acid and hydrocyanic acid, both dangerous remedies, have been also tried, resting on the physiological fact of their weakening the muscular energy, but without success, and the same may be said of ambergris The white oxide of antimony has also been spoken favourably of, but the tartarized antimony has been the most frequently employed in large doses, and again without success Nitrate of silver, which Biett used to employ at St Louis, has often given rise to the most formidable symptoms in the stomach. I opened, with Georget, the body of a person who died after undergoing this treatment during eighteen months, and we found the stomach corroded and pierced with holes in several places, and entirely denuded of mucous membrane towards the large extremity, and throughout the whole lower portion of the viscus.

Lombard has given this remedy with more caution, interrupting its administration from time to time, beginning by one-sixteenth of a grain, and augmenting to one-fourth of a grain, eight times in the twenty-four hours. This plan he tried in eleven cases, most of them experienced derangement of the digestive organs, in eight the violence of the attacks was diminished, and in one only did a cure seem to have been obtained It is, however, to be remarked that, given in these minute doses, and at intervals, the nitrate of silver did not cause that leaden colour of the skin which is sometimes found to occur after it has been too long employed. At best, however, it is like the others, but an empirical remedy, and extremely dangerous

Wormwood, digitalis, camphor, and castoreum have also been employed in vain Electricity, instead of doing good, has done harm by exciting still more the nervous system Tissot had a high opinion of musk and valerian, and the latter is the only remedy now in general use as a calmant, in powder, extract, or infusion

INSANITY IN GENERAL

I have already dwelt on the chief points in the treatment of acute maniacal delirium, and shall only here notice the views of therapeutic treatment propounded for insanity in the work of Sir William Ellis According to this author, we should, at the commencement of an attack, have recourse to bleeding proportioned to the strength of the patient he thinks this necessity still more urgent when the disease is complicated with congestion, in which case he recommends opening the temporal artery He acts at the same time vigorously on the bowels with strong doses of calomel and extract of colocynth, the head is shaved, and cold is applied morning and evening The patient is to drink night and day, barley or chicory water, in which a few grains of nitrate of potass or tartarized antimony are dissolved In the evening, sinapisms are to be applied to the soles of the feet, to be afterwards kept warm by being held over the hot steam of very hot water This course to be persevered in during several days If the general inflammatory action persist with the same violence, recourse should be had to local bleeding, by leeching and cupping, to the internal use of nitrate of potass and digitalis, the latter in small but long-continued doses, when given in very large doses, it sometimes produces, and suddenly such a prostration of strength that recovery becomes difficult.

If, from the first moment of the insanity, this perturbing treatment be persevered in, care being taken to adapt it to the strength of the patient, the cure may be rapid enough to admit of his being treated in his own house, provided the precaution be taken of employing servants that are strangers to him, and who will exact compliance with the directions of the physician The stomach is often weakened or irritated by this active treatment, and requires the exhibition of tonics with sedatives When the symptoms resist this treatment, the disease soon degenerates into confirmed insanity, from which the cure is often long deferred and doubtful.

In this second period of the disease, bloodletting must no longer be employed in quantity beyond what may be necessary to prevent serious cerebral mischief, the head may be shaved, and cupping employed on the scalp Dr. Ellis thinks he can discern the precise place for the application—the seat of pain and of greater heat We do not share in this opinion, nor do we think it so easy a matter to apply cupping-glasses to the scalp of an agitated maniac. In chronic mania he recommends, in addition to general means, the use of opium, combined with ipecacuanha, the extract of henbane, with digitalis and camphor, he particularly dwells on the attention that is to be given to the urinary and cutaneous secretions, both of which are to be stimulated by the use of nitrate of potass combined with tartarized antimony. The treatment here recommended has made some noise in France, and,

although it contains some instructions useful, especially as regards the commencement of insanity, it shows us very clearly the polypharmaceutic notions that still prevail in England in the treatment of affections of the nervous system.

But it is certain that our treatment in the beginning must be active, as any method of mere expectancy would be out of place as regards a disease which may for once be cured spontaneously, but in which, if neglected, relapse is inevitable; and it is on account of the liability to relapse that a very active treatment at first is chiefly to be insisted on.

A Course of Lectures on Diseases of the Skin.

By JAMES STARTIN, Esq., Surgeon to the London Cutaneous Institution.

LECTURE XXIV.

ROSEOLA, ERYTHEMA.

According to Willan and others.

GENTLEMEN,—A malady very closely allied, both in its nature, appearance, and attendant symptoms, to urticaria, is termed Roseola; it consists, like that disease, in a red efflorescence on the whole or any part of the body, without, however, any elevation of the patches above the surrounding skin, and with no appearance of wheals or obvious increase of density in the affected parts. By the common people it has been called bastard measles, or rose-rash, and various medical authorities have deemed it a true exanthematous fever; yet without sufficient reason, as it is undoubtedly witnessed in a chronic as well as acute form, which is never the case in the true exanthemata. The definition of this disease given by Willan, from which I shall not depart, is, "that it consists in a bright red or rose-coloured efflorescence variously figured, mostly circular or oval, without wheals or papulæ, occasionally fading and reviving: not contagious"; to which I would add, that it may appear on one part or extend to the whole body, its usual progress being from the limbs to the face and trunk.

This cutaneous disorder, like urticaria, which lately occupied our attention, exhibits the heat and redness common to diffused inflammation, which never advance to the effusive or suppurative stages, nor produce any of the abnormal products of those diseases of the skin previously described. It may occur in an idiopathic or symptomatic form, though the latter is by far its more frequent manifestation; thus it is in infantile febrile complaints, and particularly dentition (the *roseola infantilis* of Willan), that it is most frequently noticed; the greater tenuity and vascularity of the skin in young subjects being especially favourable to the development of the malady. It is not, however, confined to this period of life, but may attack mature or advanced age, and in these instances may more commonly be regarded as an idiopathic affection, constituting a true chronic disease of the skin. Roseola, however, would hold a very unimportant rank amid such affections in a practical point of view, as its nature, to use the words of an old author, "is rather a ludicrous spectacle than an ill symptom," were it not that the appearance of the eruption is apt to occasion its being confounded with scarlatina and measles, as well as with urticaria and erythema, the malady I have next to speak of.

Dermatologists, for the most part, have been content to adopt Willan's mode of considering this disease, assigning to it seven species or varieties, which I have only to recapitulate to convince you that no practical utility can attach to such minuteness of subdivision. The three first species are named *R. æstiva*, *R. autumnalis*, and *R. infantilis*, which are evidently the same affection modified by the season of the year, or by the age of the patient; the fourth is termed *R. annulata*, which is a mere form that may be assumed by any species of the disease; the fifth, sixth, and seventh on the list are designated *R. variolosa*, *R. vaccina*, *R. miliaris*, which, in fact, are but complications of the three first species with smallpox, cowpox, or miliary fever: the inflammatory action of which diseases in an irritable skin may give rise to roseola in any of its forms. This being my view of the subject, you may perceive by the chart that I propose to consider roseola under two species only, which I have named *R. simplex*, and *R. ab irritatione vel complicata*; two divisions, *localis* and *generalis*; and five forms or varieties, *sparsa*, *diffusa*, *annulata*, *acuta*, and *chronica*.

I shall now give you a brief description of these two species, which may manifest themselves in either of the divisions or in any of the forms I have indicated. *R. simplex*, which comprehends the three first species of Willan's arrangement, appears commonly in the form of scattered or diffuse red patches of irregular shapes, but mostly assuming a circular figure (sometimes so as to form rings or bands in a horseshoe form), which are not raised above the surrounding skin, and first show themselves on the limbs, suddenly or after a day or two of indisposition or febrile disorder; the summer and autumn being the seasons, and the youthful, or those whose skins are fair and vascular, being the subjects of its attacks. After a few hours the redness extends to the face and trunk, and it is sometimes so violent as to produce a general bright red tint all over the body, whilst the mouth, fauces, and throat may be at the same time invaded by the disease, constituting so great a resemblance to scarlatina that nothing but the previous history of the roseola can determine the distinction between the two affections—when the absence of a distinct fever, at least proportionate to the manifestations of the eruption, and the appearance, in the first instance, of the rash on the extremities (scarlatina primarily showing itself on the chest, face, and trunk), will determine the nature of the efflorescence. There is seldom much local irritation in roseola, unless indulgence in stimulants or improper food may give rise to it; nor is the disorder attended with constitutional symptoms beyond slight headache and restlessness, with more or less disorder of the digestive organs, all of which are usually relieved by the appearance of the eruption. The duration of this complaint varies from a few hours to a week, much irregularity existing in this respect, and exacerbations or renewals of the efflorescence being in such cases constantly observable. Some constitutions would appear to be particularly susceptible of roseola, so that the indulgence of the appetite with nearly any kind of food to a degree that slightly distends the stomach will produce it; of course the vegetable acids, wine, spices, and sweets or pastry, will be particularly obnoxious in such cases. The teething process, as must be familiar to all, is another very usual exciting cause of this rash (many infants manifesting more or less of it on cutting every tooth) which commonly subsides directly the gum has given exit to the cause of the irritation. In this, as in all other varieties of roseola, little or no desquamation of the cuticle is to be observed, which again is a distinctive circumstance, marking a difference between it and scarlatina or rubeola.

That variety of roseola to which Willan has given the name of *annulata* is the most likely to appear in a chronic form: it consists in the diffused rosy redness above described, assuming a circular or ring-like shape; indeed these roseolous flushings are almost protean in their nature—bands, horseshoes, stripes, crescents, &c., being observable, often in the same case, at different periods of the attacks of the disease. Amongst ladies of the *beau monde* this otherwise trivial malady constitutes a veritable torment, as the flutter and agitation of the fair one, in the performance of the toilet or in the anticipation of a fashionable *réunion*, is quite sufficient to bring forth the lurking blush, and as the face and neck offers the most vascular surfaces it is in these situations that the vagaries of the disorder are more annoying than hurtful to the fair votary, an indelible mark being imprinted for some hours on those charms which most meet the eye; thus, as it were, exhibiting an hieroglyphic intimation of the baneful effects of late hours and crowded apartments

Roseola ab irritatione vel complicata cannot be said to differ in any of its external manifestations from the simple species of the disease I have now described; it is the frequent accompaniment of many cutaneous eruptions; variola, vaccina, and miliaria have been especially cited by Willan as those maladies from the irritation of which it is most commonly witnessed. It is also often attendant upon rheumatism, gout, burns or scalds, or other excitements of the corporeal surface; yet under all these circumstances it presents the same unimportant and transient nature, constituting the first evidence of cutaneous inflammation, no effusion having taken place, and the mere pressure of the hand being sufficient for the moment to dissipate all signs of the disease.

I must mention, however, that in this species of roseola a degeneration into erythema, or œdema, to be presently noticed, will be most commonly found; indeed the resemblance between the complaint under consideration and erythema is such that authors have hesitated when describing them as separate maladies, which has been done only from a deference to the opinions of Willan, who so deservedly has exercised an undisputed sway over this department of medical science. I think, as I have said before, when speaking of lepra and psoriasis, of impetigo and eczema, of lichen and prurigo, of acne and sycosis, of ecthyma and rupia, and of other maladies of the skin separately considered, that a union of two or more under one common description and definition would be attended with useful results, theoretical as well as practical; and I am inclined to extend this observation to roseola, erythema, and perhaps œdema—the latter name not being applied by me as a synonymous term with anasarca, but to a peculiarly inflammatory state of the skin and subjacent cellular tissue, to be presently mentioned. With regard to the causes of roseola, it may be gathered from the remarks already made, as was said of urticaria, that they may be very commonly assigned, and are found to consist in errors of diet, in disorder of the digestive organs, or in the irritation of some other local disease; in a few instances, however, the affection would appear to be idiopathic, and then no reason can be adduced for its appearance. This is the case with an epidemic form of the complaint which now and then prevails in hot weather or during the fruit season; though in the latter instance gastric derangement, common at such periods from indulgence in food to which the stomach is unaccustomed, and the natural determination of blood to the skin owing to the high temperature of the atmosphere, may be regarded as the proximate causes in predisposed constitutions.

It must be obvious that the treatment required for roseola must be of the simplest kind; indeed the disease may be regarded as a salutary effort of nature, which in the majority of instances needs no medical interference.

In the acute forms the causes must be sought for and removed either by gentle aperients or

emetics, whilst a few drops of some mineral acid combined with the bitter of orange peel, or other stomachic, will be all that is necessary to restore tone to the digestive organs.

Where much pain attends, colchicum, or the iodide of potassium in small doses, will be found of much service, and the latter remedy has seldom disappointed me in the more chronic forms of the complaint; of course it may be variously combined to meet the exigencies of the case, and the vapour or tepid bath should be used as an auxiliary. The external means consist in spirit lotions containing a little borax or distilled vinegar, and eau de Cologne diluted with water in the proportions sanctioned by the custom of the patient, is the most usual domestic remedy, and commonly fulfils all the indications required. I have occasioned models of roseola to be prepared for your inspection, but I certainly shall not waste your time in the detail of cases of this evanescent affection, which is rare amongst the patients presenting themselves here for relief; indeed, I think that, contrary to what is observed of most cutaneous diseases, roseola may be said to occur ten times in the higher to once in the lower ranks of society; hence it is of some importance that a correct diagnosis should be formed of the disease, as a mistake, even upon so simple a subject, is always better avoided.

The constitutional disturbance attending the more important maladies with which it may be confounded—as, for instance, measles and scarlet fever—and the comparatively regular progress of the latter affections, connected with the previous history of the eruption, as I have already detailed, will seldom or never fail to furnish data preventing an erroneous conclusion. The difficulty of diagnosis is, however, considerably augmented when determining whether the patient may not be a sufferer from erythema in its early stages; but I should hope I have said enough to settle the diagnosis if ordinary attention be granted. Yet the models I hand round may serve better than any language to make you acquainted with the manifestations of the disease. You must, if you please, make a little allowance for the exuberance of colour in some of those recently prepared, as, were they kept in strict accordance with nature, they would be useless a twelvemonth hence.

Erythema was treated of, under the name of erysipelas, by Galen and Celsus; and it still retains this designation, amongst non-professional persons, in common with any other eruption which has heat, redness, and some degree of swelling, for its more prominent signs. By medical men, also, the term erythema is often applied under the same circumstances; as, for instance, to lichen, or to eczema in some of its forms, particularly that which is occasionally produced by mercury. I am sure I need not comment on the incorrectness of this mode of considering the disease, as no papules or vesicles are ever found, unless they exist in complications with other complaints to which they properly appertain. Erythema may be defined to consist in a non-contagious, circumscribed, bright-red, inflammatory eruption on the skin, of variable extent (which is slightly raised above the healthy parts, whilst more or less increased density of the affected portions is always observable), attended with heat, tingling, and burning pain, and sometimes with considerable pruritus. This state may terminate in cuticular desquamation, and disappear after a short period; or it may become chronic, and be accompanied by excoriations, ulcerations, and even gangrene.

It will be perceived, from this statement, that here are all the common products of simple inflammation, and, in fact, erythema may be regarded as the lowest type of true phlegmonous action in the human skin; it is a degree more violent than roseola, which may rather be compared to a permanent blush than a genuine inflammation, as there is no swelling consequent upon the effusion which so constantly marks the early stages of that phenomenon. Willan gave six species to erythema, and his followers have added others, of which the seven most important are thus named:—E. fugax, E. læve, E. marginatum, E. papulatum, E. tuberculatum, E. nodosum, and E. intertrigo; but I am disposed to refer the first on the list to roseola, and the second to œdema, of which I shall presently speak, whilst the others will be distributed, as I have written them on the chart, into five species, viz., *E. simplex*, simple papular erythema; *E. excoriatum*, abraded or excoriated erythema; *E. nodosum*, nodose erythema; *E. tuberculatum*, tubercular erythema; and *E. ulceratum*, ulcerated erythema. Each of these species may be local or general, or distributed into the five forms I have written as scattered, diffused or confluent, marginate, between contiguous surfaces, or chronic. This disease, in any of the divisions I have specified, is much more frequently an idiopathic affection than roseola, of which it would almost appear an advanced stage; it may also, like that affection, be a symptomatic manifestation of various visceral disorders, or of local irritation on the skin. There is seldom or never any constitutional disturbance arising from the presence of erythema, but, on the contrary, this state may be the cause of the eruption, and disappear or be much mitigated when the external symptoms are most severe. I shall trouble you with a concise description of the species of the disease laid down in the chart, which you will find illustrated by the models I have caused to be prepared for your inspection.

E. simplex, which, in its papulated form, is exemplified by the model No. 6,134, taken from the leg of a gasfitter, it is unnecessary to describe, as it perfectly corresponds with the general definition given of the complaint. I shall only inform you, therefore, that the appearances presented may be local or general, and may be manifested in any of the forms I have indicated. You observe it there in a chronic state, as it had occupied the locality on which it is situated some months. I have before told you there is a little elevation of the inflamed portions above the surrounding skin, and you will notice the markings of the cuticle to be more conspicuous from this circumstance, and as it were grooved here and there, whilst desquamation of the epidermis is going on, giving the inflamed spots a rough irregular surface, manifest both to the eye and touch.

E. excoriatum is a name I have ventured to apply to a species of the disease attended with excoriation of the surface, which, though most frequently witnessed in the flexures of the joints, constituting there the E. intertrigo of Willan, yet is to be observed very commonly on the lower extremities, on the insides of the thighs, and in patches on various parts of the person, not subject to "the attrition of contiguous surfaces." It commences by a red blush, as E. simplex, which in a short time becomes raised a little above the skin, when its surface appears moist, and the cuticle is found detached. If close attention be paid to this process, it does not appear that vesicles are formed as in eczema, but that the portions of the cuticle covering the quadrilateral spaces enclosed in the lines which mark the part become loose and are detached, from a little fluid effused beneath them, when the surface is left red and raw, secreting a yellowish serum that does not form crusts, but which possesses a faint unpleasant odour. It is in this species of erythema that ulcerations and sloughing are occasionally observed; but this is chiefly the case in the lower extremities, though it may occur on any part of the body, and when in this advanced stage would be referred with more propriety to a species of œdema. The portions of the integument affected with E. excoriatum, are of a dark red tint, and often pit when pressed with the finger, leaving a whitish mark, from the pressure having partially emptied the loaded vessels. This species of erythema is observed in the bedridden, on those parts subjected to pressure, or when the urine, fæces, &c., have irritated the skin by constant contact.

E. nodosum is not a very uncommon complaint; I perhaps witness it twice a month; and, though females are liable to it in twenty instances to one of males, yet the latter are occasionally affected. It consists in the somewhat sudden eruption of painful swellings, resembling nodes, of a pale red colour, and occurring chiefly on those portions of the integument which immediately cover the bones—the shins are, by *far*, its most frequent position; but the forearm, the forehead, the scalp, the lower jaw, the clavicles, or over some of the ribs, are its occasional situations, according to my experience. It is not unfrequently preceded for a day or two by pains like rheumatism, a white tongue, and constitutional disturbance, whilst the pain is much augmented by motion, or by the heat of the bed-clothes. In my opinion it is a species of rheumatism, attended with an erythematous or roseolous blush: and, like that disease, yields to colchicum and diaphoretics. The chlorotic state in young girls, and the debility attending pubescence in boys, appear to be predisposing causes. I have once or twice seen E. nodosum after the age of thirty, and that in females; consequently it would appear, as Shakspere has it, "a malady most incident to maids."

E. tuberculatum is a very rare disease, yet I have seen it many times, and show you not only a model of it, but a living example: you will observe that this man's condition very well agrees with the description given by Willan,—"that it is accompanied with great languor and debility, and that the patches are raised above the skin, are harder than the surrounding integuments, and present a dark livid hue, with (at the present time) a slight desquamation of the cuticle. When this man first applied, about a fortnight ago, the tumours interspersed amongst the patches, as mentioned by Bateman, were also observable and readily to be distinguished by the hand; at the present time they have nearly, if not quite, disappeared, though the erythema remains. My experience in this disease corresponds with that of Willan, who only witnessed it three times—"that remedies appear to be of little avail," either in averting the present symptoms, or in preventing the subsequent hectic that commonly supervenes in this rare and little-understood malady. I have seen E. tuberculatum assume the form Willan has described as E. marginatum, and then it has appeared to me to be connected with disease in the circulatory system. I show you a remarkable model of this disease—I mean *E. marginatum* of Willan—which I should call E. simplex marginatum; and, as most of the body of this poor girl was similarly affected, I may add the division *generalis* to the species and form of the affection. I shall speak of this case again presently, when you will find that the erythema was symptomatic of disease of the heart.

The last variety of erythema on the chart, to which I have affixed the name of *E. ulceratum*, I shall not here particularize, beyond mentioning that it is the not unusual termination of E. simplex and E. excoriatum. When I have to speak of ulcers, I trust you will find that this division of the disease under our notice, will meet with all the consideration it deserves.

The causes of erythema, as I have already observed, are more obscure than those of roseola, but where they can be traced, they may be said to be very nearly, if not quite, identical. As the complaint consists of little more than a subacute form of common inflammation, manifesting itself on the surface of the body, any cause to which inflammation may be assigned will be found to prove an origin of erythema; thus atmospheric vicissitudes, errors of diet, disturbances of the circulation, and local irritation, constitute the most usual sources to which the complaint is to be attributed. These causes once discovered, the treatment becomes most simple, as it consists in an endeavour to remove them upon the general principles which actuate us in the treatment of inflammatory diseases having no specific nature, which, I need not tell you, are soothing and antiphlogistic. In the chronic forms only of erythema it may be necessary to recourse occasionally to the system of internal external counter-irritation I have so consta advocated; but this system must be confined such cases only. I will, however, relate an instance or two, in the belief that I shall thus at once present you with an insight into my views, and with examples of the good or bad effects of carrying them out; so that you will be able to let the matter rest upon your own conclusions.

As on former occasions, I shall keep to those cases from which models have been taken, as far as they will serve, but I have no casts of the acute forms of the disease; their transient nature, and the little there is to represent, beyond the redness of the

surface, preventing my employing the services of the modeller. The first instance to which I have to request your attention is a case of *erythema simplex*. Henry Axelby (9), of Princes-street, Stamford-street, applied on the 31st of last October, having suffered two weeks from an eruption of red blotches on his forehead, face, and one side of his neck; they were of a bright red colour, and there was considerable swelling of the parts affected, so as nearly to constitute erysipelas, from which, however, the complaint was to be distinguished by greater chronicity in the inflammation, and by the papular form of the blotches, which revived and declined frequently. Some degree of constitutional disturbance attended this disease, but by the patient's account he had been better since the appearance of the eruption, though much pain and burning were experienced in the situations of the erythema. He had a white tongue, as seen in rheumatism, and his bowels were inactive. His parents attributed the eruption to their child having got wet and chilled, which brought on a pain in all his limbs, attended with shivering and feverish symptoms. This was a well-marked case of simple acute papular erythema, and the cause assigned for its appearance is the common origin of inflammatory action in any part of the body, which no doubt gave rise to the disease in this delicate boy. The treatment was therefore similar to what would have been directed had any other part or organ been affected instead of the integument, and consisted in a brisk calomel purgative, followed by a diaphoretic mixture, containing tartar emetic, every four hours, and an evaporating lotion to the parts affected; low diet and repose. In three or four days there was very evident decrease of the erythema, and the general health, as regards the feverish state attending the disease, was improved. An acidulated saline aperient, containing a few drops, for a dose, of the wine of colchicum, was therefore substituted for the antimonial diaphoretic, whilst the lotion was rendered slightly stimulating as well as evaporating by the addition of borax. A week's perseverance in this change removed all the symptoms, save a little roughness of the parts affected from desquamation of the cuticle.

The next case I shall read is a chronic form of the same affection, which is represented by the model numbered 6,530. The patient from whom it was taken was a gasfitter, named Charles Lewis, aged thirty-five, residing Princes-street, Drury lane. He had suffered nine weeks from this *Erythema papulatum chronicum*, and it had occasioned him so much burning pain and uneasiness that he had been a patient of a neighbouring hospital for some weeks before his application here, which was on the 14th of November. The leg from which the cast is taken was the only seat of the disease, and no cause could be assigned for its origin, unless standing constantly at the bench, filing, &c., may be considered one, in a constitution somewhat injured by excesses, and with an incipient varicose state of the veins of the affected limb. I have before described the appearances presented in this man's case; the treatment adopted consisted in the local application of a weak mercurial ointment, which was covered by a compress, wet with warm water, and supported by a bandage. The internal remedies consisted in a dose of calomel and opium, at bedtime, every night, and a dose of colchicum and liquor potassæ, in a draught of mint-water, twice a day. On the 1st of December, after these means had been used a fortnight, he presented himself much relieved; and he was directed to persist in the same remedies; gradually, however, diminishing the doses and the frequency of taking them. As the erythema disappeared, he absented himself till the 2nd of January (last month), about seven weeks from his first admission, when he was quite free from the disease; no occasion for changing the remedies first employed having been called for. If this model be attentively observed, it will be perceived that there is an appearance of abrasion or excoriation here and there, as though ulceration were about to commence. Nor is such appearance illusory, as ulcers on the legs are preceded by this kind of appearance, as I shall have occasion to repeat when treating on that subject. The wet compress and bandage were recommended in this case as the most effectual means of averting such an occurrence, and they appeared to have the desired effect. The state of erythema presented by this model may also be considered to indicate the transition of E. simplex to the next species of the disease I shall illustrate by a case, which is an instance of *Erythema excoriatum intertrigo* that had assumed the chronic form, and is exemplified by the model of the elbow-joint of Sarah Slate, at this time a patient of the institution, having been admitted on the 12th of December last. The age of this individual is seventy-two, and she has suffered ten months from her erythema, which she states commenced from poverty and bad living; to which causes I may add, that of neglect of fitting ablutions, so common at her advanced period of life. The first manifestations of the disease, as is usually the case, were in the hams, at the back of the knee-joints; and they appeared as a red patch, attended with heat and tingling, which soon became moist, and extended to other parts of the body subjected to the attrition of contiguous surfaces. The discharges from this disease were most disagreeable, and resembled decaying wood, or a damp cellar inhabited by cats. There was much constitutional disturbance occasioned by the irritation and the want of sleep, which it naturally produced.

This patient had considerable *embonpoint* remaining, notwithstanding all her sufferings, and this much contributed to her discomfort and the continuance of her erythema. An examination of the affected parts showed no pimples or vesicles, but a smooth, red, shining surface, intersected with deep grooves, which were the natural markings of the parts appearing more conspicuous from the swelling and tension of the effusive inflammation. The whole surface was kept moist by the discharge I have mentioned, and seemed deprived of its epidermis. The treatment adopted to relieve this poor woman was strictly palliative. The tepid bath; a lotion of milk, containing half an ounce of liquor plumbi acetatis to the pint; alterative mercurials at bedtime, and diaphoretic aperients during the day. She has attended weekly since her admission, and the erythema has continued to amend under this treatment, so that at the present time all constitutional symptoms may be said to have left her; consequently, on the 7th of this month, when I last saw her, there were visible the mere remains of her complaint only, consisting in a little redness, and dry desquamation of the cuticle in one or two situations—appearances I have found yield to a few drops of Fowler's solution, combined with an alkali, which I accordingly prescribed. The model now presented to your attention represents a very rare form of erythema, that I have very constantly found attendant upon disease of the heart or circulatory apparatus, and, consequently, to resist all means of cure. Sophia Collings, aged twenty-one (of Green-street, Stepney), admitted June 25, 1845, is the name of the young woman from whom it was taken; she had suffered six months the appearances exhibited on the cast of her face, which very accurately represents the disease; the hands, arms, and legs were also affected, but not the body. I should mention that on the latter situations the erythema was papular; it also seemed here and there to assume a circular figure, and on passing the hand over the part it gave the sensation of irregular bands firmer than the healthy integument being spread beneath the surface, which was very slightly raised where these patches or papulæ were situated: they very much kept to one position, but often faded and revived, sometimes assuming a livid or purple hue.

The statement of this patient would lead me to believe that this eruption had been rather sudden in its attack, not having been preceded by any remarked indisposition beyond slight occasional dyspnœa after exertion or walking up stairs. The pulse was fluttering and irregular (about 75), the heart's action being very diffused, and its pulsations not so audible as is natural—an irregularity not amounting to an intermission occurring every fourth or fifth beat, when I thought I could distinguish a *bruit de soufflet*. Various constitutional means were essayed for the relief of these symptoms without any marked benefit; and, as the case was curious and interesting, I obtained on several occasions the valuable opinion of my friend and colleague Dr. Southwood Smith upon it; but, though five or six months have passed over since she first attended here, I do not think any improvement has occurred; indeed, latterly, she has become anasarcous, and I have detected fluctuation in the abdomen, so that I fear her case may be regarded as affording little reasonable hopes of recovery. I have not entered into a minute detail of the treatment employed in this case, inasmuch as I regard this erythema as entirely symptomatic, and I do not profess to enter into the general principles which direct our remedies under such circumstances; yet, as I have witnessed this variety of the disease I have endeavoured to describe on several occasions, I considered it necessary to bring the present illustration of it before you.

Erythema nodosum I have been unable to exemplify by a model for two reasons: the first is, the rare occurrence of the affection at this season of the year; and the second, that, as it occurs for the most part in young delicate women, they have a considerable reluctance to allow a cast to be taken of their legs—on the shins of which, you are aware, the erythema is commonly situated. I have indulged this feeling of delicacy until an opportunity should present where it did not exist in a marked degree; and, as this has not occurred, I therefore shall briefly recount the course of one of the latter instances of the affection, to show you that parties in adult age may be the occasional subjects of its attacks, and that it may supervene during the existence of other maladies of the skin.

E. Trebble, aged 38, residing opposite the Almshouses, Hoxton, was admitted during the summer a patient of this institution, suffering from lepra vulgaris, which manifested itself only on the elbows and knees. This in a month or two yielded to the remedies employed, and I lost sight of the patient for some time; and she discontinued taking medicine or using the baths.

About a month ago I was summoned by her husband to visit her, with what was considered an attack of erysipelas, as she was confined to her bed. The case proved to be one of *erythema nodosum*. It would appear that she had been suffering from influenza, as she termed it, and the great debility characterizing that complaint was very evident; when suddenly both shins began to swell as though they had been struck here and there, and contused. These swellings, which were irregularly scattered on the fronts and sides of the tibiæ, were prominent, red, and painful to the touch; somewhat oval in shape, varying from the size of a gravy spoon to that of a dessert spoon. The lepra also had begun to show itself again; an occurrence, no doubt, arising from the cutaneous irritation present, which, you have been informed, very commonly excites or revives an old morbid habit, of whatever kind that may happen to be.

The constitutional derangement in this case was considerable, the tongue being loaded with a white coat, and great prostration of the vital powers being present; I, therefore, directed a light tonic, combined with a mineral acid, twice or three times a day; a dose of colchicum, and an opiate at bedtime, and a little wine with the meals, which were to be light and nutritious. The local pains and inflammation were assuaged by an evaporating lotion applied warm, and by rest in the horizontal position. These measures had the desired effect, so that in ten days this patient was enabled to attend here, and she is now under treatment for the leprous disorder for which she originally applied, all remains of her erythema nodosum having vanished. The last example of erythema I have to cite is that very rare form of it represented by the model 6,944, labelled *E. tuberculatum*, cast from the leg of Morris Conroy, aged forty-nine, of Bayswater. I shall, when we next meet, show you this patient, so that you can compare his disease with its representation. His statement is that the eruption appeared on his arms and legs; three months ago, like small hard lumps or tubercles, which soon became livid; but that he had been otherwise ill, and, having had no regular employment, his diet had been very bad,

which his appearance—that of an asthenic individual of sixty (his age being forty-nine)—completely verified. The treatment adopted has been tonic; the vapour bath being the local means resorted to. He attended on Tuesday last, as I understand, improved in health; but, as I did not see him, his attendance to-day was not arranged. I will take care, however, that you shall witness this disease, which is so rare as never to have been seen by Bateman, and three times only by Willan.

The next subjects I shall consider will be *Œdema* and *Erysipelas*.

ORIGINAL CONTRIBUTIONS.

REPORTS ON THE DISEASES OF FEMALES.

By EDWARD RIGBY, M.D.,

Fellow of the Royal College of Physicians, Senior Physician to the General Lying-in Hospital, Lecturer on Midwifery at St. Bartholomew's Hospital, Examiner on Midwifery to the University of London, &c.

I think it will be better not to illustrate the subject of cephaloma by cases until I have offered a few remarks on the principal features of hæmatoma, or fungus hæmatodes, as it is more commonly called. It is a soft, organized, vascular, and somewhat spongy mass of a dark livid or purplish hue, arising by a broad base usually from the body or fundus of the uterus, and irregularly divided into numerous lobes and nodules, having an appearance, consistence, and feel of loose cellular tissue, into which blood has been extravasated from a powerful vessel, and has solidified; when cut into, it resembles a mass of coagulated blood which is divided into irregular portions by an interstitial cellular tissue, and, like cephaloma, its surface is covered by a ragged vascular membrane, which is probably a production of the lining membrane of the uterus. It exhibits a much greater degree of vascularity than in cephaloma, although the vessels occur in the same sort of patches on the surface, and between the lobes of which the mass consists.

Although its progress is usually more rapid than that of cephaloma, it does not seem to pervade the uterine tissue so generally in the early stages of its course, but is then more isolated, and appears to be more immediately surrounded by structure which is healthy, or nearly so. Dr. Hooper, in his beautiful plates on the morbid anatomy of the uterus, says that it is very rarely found assuming a tubercular form; but if I may judge from those cases where, from having its commencement on the os uteri, I have been able to see the disease during life, and at an early stage of its progress, I should certainly come to the conclusion that it frequently begins as an isolated nodule or tubercle—in fact, much as it is usually observed to commence in other parts of the body where it can be more readily examined, as the lip, breast, &c. When seated in the cavity of the uterus, its precise condition at an early period can never be ascertained, for the very existence of the disease can scarcely be decided upon until its extent has become so considerable as to be reached by the finger through the os uteri. Like cephaloma, it assumes a polypoid form when it projects into the vagina, but it is much softer and more brittle; whereas a polypoid mass of cephaloma is tolerably firm. When occupying the uterine cavity its structure is very delicate, for it bleeds profusely on the slightest touch, and severe attacks of hemorrhage are not unfrequently induced by any sudden shock, as coughing, &c. It makes its way with great rapidity into the bladder and rectum, forming in these cavities a similar irregularly lobulated tumour as in the uterus, the whole consolidated into one mass of disease.

The symptoms of hæmatoma are so much the same with those of cephaloma that it might be fairly asked, how can the one be distinguished from the other? There are the same derangements of the menses, the same profuse discharges, gastric irritation, and gradually increasing state of general cachexy. Still, however, there are some points of diagnosis which are, perhaps, worthy of note. The os uteri is not gradually destroyed by the peculiar pulpy softening, as in cephaloma, but it becomes obliterated and lost in fungoid swelling and growths, &c. The body of the uterus is usually larger than in cephaloma; the attacks of hemorrhage are far more profuse; the slightest touch is followed by blood, and the most gentle and cursory examination frequently produces a severe discharge. The course of the disease, as I have already remarked, is more rapid than that of cephaloma; so that, if the symptoms and characteristics now enumerated be compared with those which I have given in my description of cephaloma, I think that a sufficient mass of evidence may be obtained in most cases for forming a tolerably correct diagnosis.

The general treatment is precisely the same as that of cephaloma—mild alteratives and laxatives, combined with, or followed by, chalybeate medicines, seem to be the means best adapted for assisting the powers of the system in their struggle with the disease. The same lotion of the ferri sulph. c. extr. conii, I have found also serviceable in hæmatoma.

From the irregularly lobulated character of its form, its broad base, and brittle structure, it seldom gives any chance of a portion of the mass being removed by ligature; on the other hand, when it occurs as an isolated tubercle on the os uteri, and therefore within reach of the speculum, it may be successfully removed by escharotic applications. These cases, however, are rather the exceptions than the rule.

I am sorry to acknowledge that I have recorded but few cases of fungoid disease; but the majority of these I have seen have been hospital cases, which have come before me at a very advanced stage, and that only for a short time; in many instances they have been admitted in a dying state; in others, where the system was still capable of deriving benefit from remedies, they have again returned home on feeling themselves better.

A. M., aged 44, mother of four children.

June 11, 1840. Continued watery discharge, with occasional severe pain about the uterus; bowels confined; pain on evacuation of the rectum and bladder.

Her last labour was sixteen years ago, and until lately her health has been always good, and the menstruation regular; subject to slight leucorrhœa occasionally; has been accustomed to walk a great deal. At the beginning of the present year the catamenia continued for five weeks without stopping, followed by leucorrhœa and bearing-down pains, which she attributes to over-exertion, great exposure to cold, and excessive drinking at that time.

Exam. per Vaginam.—Uterus large and apparently immoveable; os uteri nearly resting on the perineum; much enlarged and open; lips thick and swollen, firm, but not hard,—surface smooth; cervix very short. The finger passes into a large cavity, the sides of which are pulpy and fungoid. The examination produced much suffering, but no hemorrhage; a fragment of soft brain-like matter, which was very fetid, came away with the finger.

℞. Ferri. sulph., extr. conii, aa. gr. viij.; aq. distill. ℥j.; ft. lotio. Semicup. calid. alternis noctibus.

June 22. Less pain; discharge thick, and occasionally lumpy; greater difficulty in passing water.

℞. Sp. ammon. arom. m. xx.; infus. gentianæ, aq. menth. pip., aa. ℥vj.; ft. haustus. ter die sumend.

℞. Morphiæ hydrochlor, gr. ¼ o. n.

We are still a good deal in the dark as to the manner in which malignant diseases commence; perhaps the only facts of any certainty which we possess on this subject are that vascular congestion, usually of an atonic character, had existed for some time previously in the part; and that this congestion was the result of, or at any rate connected with, long-standing derangement of the assimilating functions. The patient had confessedly lived a hard life, in every sense of the word, and was now coming to the age at which the menses begin to disappear—a period peculiarly liable to uterine disease.

The large and immoveable uterus, the short cervix, tumid lips, and open mouth, with the cavity beyond filled with pulpy structure—the previous hemorrhage and history of her case—would leave little doubt that malignant disease existed. The absence of nodular growths from the inferior segment of the uterus, the capacity of its cavity not blocked up by irregular lobulated masses of fungoid structure as in hæmatoma; the absence of any amount of hemorrhage after the examination; and above all, the appearance of a portion of brain-like matter, leave little doubt that this was a case of cephaloma. As no serious derangement of the general health existed, I merely prescribed a little simple medicine to regulate the bowels, and the lotio ferri c. conio, to which I have already alluded. The discharge became thicker, and, as a usual consequence, the pain was mitigated; but the increasing difficulty in passing water, showed too surely the progress of the disease. Feeling a temporary improvement she left the hospital.

M. J., aged forty-six, mother of eight children; has had two abortions, the last was about three years ago, at the third month of her pregnancy.

Feb. 15, 1840. Pain around the hips and loins, with difficulty in evacuating the bladder and rectum; general health not much affected; has a sanguineous watery discharge. The catamenia became irregular about a twelvemonth after her last abortion, both as to the intervals and duration of the periods, the former being sometimes five weeks, the latter a fortnight.

Exam. per Vaginam.—Os uteri low down in the vagina, its edge nearly indistinguishable from a complete fringe of soft excrescences growing from it, and from the canal of the cervix. As far as the finger can reach is a quantity of fungoid growth to be felt, which easily breaks down and bleeds.

℞. Pil. hydrarg., extr. hyosc, a.a. gr. v., o.n.

℞. Ferri. sulph., zinziberis, a.a. gr. j.; extr. gentianæ, gr. iij. m. f. pil. j. mitte tales xij.; sumat ij. bis. die. Lotio plumbi.

Feb. 22. The discharge is no longer coloured with blood, but has a yellowish tinge. Omit pil. hydr. c. hyosc. Rep. alia.

March 7. Much pain and difficulty in passing water; bowels confined, with bearing down, and apparent obstruction in passing fæces; the discharge is yellow and but little diminished in quantity; latterly it has been again mixed with blood; gets little or no rest; has been obliged to take laudanum twice a day to relieve pain.

℞. Pil. ferri sulph.; extr. hyosc, a.a. gr. v., o.n.

℞. Aq. menthæ viridis, aquæ distillatæ a.a. ft. ℥vss.; acidi sulph. dil. m. x.; syrupi rhœad. ℥ss. m.; adde magnes. sulphatis ℥ij. solve; ft haust bis. die. Rep. lotio.

April 25. Not so well in general health and feeling; much bloody discharge, with clots during the last week; much pain and difficulty in passing water. Rep. med.

May 23. Occasional bloody discharge; at other times it is thin and watery; much pain and difficulty in evacuating the bowels and bladder; general health is tolerable. Rep.

I would not have selected this case, the report of which is rather imperfect, had I taken notes more frequently of malignant disease when considerably advanced. It suffices, however, to illustrate a point to which I am desirous of directing attention, viz., that malignant disease frequently exists to a very great extent without seriously breaking up the general health immediately, and that although we know it is incurable, and will, of a certainty, ultimately destroy the patient, it is exceedingly difficult and hazardous to give any very decided opinion as to the duration of the patient's life. In the above case the rectum and bladder were evidently becoming implicated in the disease, and at one time there was a suspicion for a while that she could no longer retain her water. From the condition of the os and cervix uteri, and the history of the symptoms, I presume that this was also a case of cephaloma.

A druggist and his pupil have recently been brought up before the tribunal of Correctional Police of Paris, on a charge of manslaughter for having sold syrup of poppies to a woman for administration to her infant. The child died, and the accused have been remanded

ON THE ABSORPTION OF URINE IN THE BLADDER.

By M. BOUCHARDAT.

Translated for the MEDICAL TIMES by ALFRED MARKWICK, Esq., Surgeon to the Western German Dispensary, and formerly Externe to the Venereal Hospital, Paris, &c.

Is there any absorption of the urine that passes into the bladder and remains there during a longer or shorter period? Is the portion absorbed richer in water than the urine remaining in the bladder?

The solution of these questions is interesting in a physiological point of view, and still more so as regards hygienics: for if the urine be absorbed, and the principles destined to be climinated from the body be again carried into the circulation, we can easily understand how disorders of more than one description can result. There are two ways of solving these questions:—1st, by analysing separately the urine that escapes from one of the ureters before it has been allowed to remain in the bladder, and that which has remained in the bladder, and which has passed into it through the other ureter; 2nd, a salt that can be easily found in the blood may be injected into the bladder of an animal. I shall relate at the end of this article the experiments I have performed on the subject, and will now allude to the analysis of the urine passed by each ureter, and collected—the one after it had remained in the bladder, and the other immediately it escaped—by means of a urethro vaginal fistula. This interesting case was communicated to me by M. Trifet, House Surgeon, under Professor A. Berard. It is as follows:—

Jeanne Bolvent, aged 40, charwoman, living at Terré (Ille et Vilaine), entered the Hospital of La Pitié on the 5th of March, 1845. She is of a good constitution, and has always enjoyed excellent health up to the time of the confinement that occasioned the accident for which she came into the hospital. She married at the age of thirty-two, and remained four years before she became a mother. The labour was natural, and, after lasting from two to three hours, ended in the birth of a daughter. Two years elapsed, and she again became pregnant; the labour, however, was this time both much longer and more difficult, and lasted nearly three days. The child, a female, which presented by the head, was stillborn. The patient says the forceps were not employed, in consequence of the head of the child pressing on the symphysis of the pubes, and of the difficulty, as the accoucheur stated, of introducing them at this distance. Nevertheless, the lochial discharge took place regularly, and, everything appeared to be going on favourably. She got up at the end of the fourth or fifth day, and began to eat, but was still perfectly ignorant of the infirmity under which she now labours; and it was ten or twelve days before she noticed that the urine oozed out involuntarily. The medical men of the district recognised the nature of the disease, and sent the unfortunate patient to Paris with a certificate declaring her to be affected with a vesico-vaginal fistula. She came with a full determination to undergo any operation calculated to relieve her of the infirmity.

When she entered the hospital, the urine was observed to be continually making its escape from the vagina, and the patient declared that she experienced several times a day a desire to make water, and that she was able to excrete a tolerably large quantity at a time. Moreover, a rather large tumour could be felt in the hypogastric region, and on the introduction of a catheter into the bladder, three or four centilitres of urine were drawn off. It being very evident that the fluid which constantly escaped from the vagina was urine, that the bladder was capable of containing a pretty good quantity, and that the patient voided it voluntarily, expected to find a very minute aperture on the vesico-vaginal partition; but, notwithstanding the most careful examination of this partition, it was impossible to discover the smallest opening. An injection was thrown into the bladder through the urethra; none of the fluid, however, was observed to pass into the vagina, neither could the opening be found out by means of the catheter; and it was necessary to discontinue this first examination without discovering anything.

On March 6 she was examined a second time, but with no better success than on the preceding day. All that could be ascertained was, that a certain quantity of urine was constantly escaping from the vulva, where it produced a very painful irritation, and an exanthematous and vesicular eruption, extending as far as on the buttocks. It was also ascertained, as on the first occasion, that a portion of the urine collected in the bladder, and was evacuated by the natural passages and by the sole efforts of the patient.

On the 17th we again sought for the fistula, a large *speculum brisé* being used for the purpose, and, after a careful examination, were about to give up all hopes of finding it, when we perceived a limpid and apparently urinous fluid ooze through the orifice of the neck of the uterus. From that moment the idea of a vaginal fistula was entirely abandoned, and a uterine fistula alone thought of. M. Berard tried to discover the opening in a direct manner by introducing a stilette into the orifice of the uterine neck, and a catheter into the bladder, and then attempted to bring them into contact, but failed; the two instruments being separated by the whole thickness of the vesico-uterine wall. The patient being now fatigued, and complaining of very acute pain in the hypogastrium, the examination of the parts could no longer be continued.

18. In consequence of these exploratory trials, the patient experienced slight shiverings, general uneasiness, headache, and pains in the abdomen. (Abstinence, seidlitz water, cataplasms.) (a)

19. The pain in the hypogastrium increases and extends to the left lumbar region. The tongue is clammy, the mouth bitter, and the thirst excessive; there is also anorexia and nausea; the sleep is agitated and the pulse frequent. (Ten cucurbitulæ cruentæ on the painful part; poultices, lemonade, abstinence.)

21 and 22. The symptoms still continuing, the cupping was again had recourse to.

23. The pain is less acute, the pulse less frequent, the nausea is disappearing, and the reparatory sleep returning.

26. The amelioration continues, and the appetite has considerably increased; food is now given to the patient.

April 6. The patient's health being completely restored, M. Berard, still believing he had to do with a vesico-uterine fistula, and hoping to obtain a cure by preventing the urine from coming in contact with the edges of the opening, introduced a double-current catheter in the bladder through the urethra, for the purpose of producing a continued irrigation of cold water. The fluid entered the bladder through one of the canals of the catheter, and escaped with the urine through the other. This remedy, however, was obliged to be discontinued, as the accidents became again developed after two days' perseverance in its application.

8. Shivering, headache, anorexia, nausea, and pains in the abdomen, particularly in the left lumbar region, so acute as to cause the patient to cry out when the least pressure was made on the part; the tongue was white and the mouth clammy. (Seidlitz water.)

In a few days these symptoms entirely disappeared.

On the 13th the patient appeared completely restored, when suddenly, and without any known cause, she experienced very acute pain in the left lumbar region; the urine no longer escaped through the fistula, and collected in the bladder in about the same quantity as on the previous days; after three or four hours the urine again flowed by the vagina, when the pain disappeared as if by enchantment. The patient informed us that she had several times noticed that the urine did not flow from the vagina, and that each time she had been attacked by pain in the left lumbar region, which disappeared immediately the excretion of the urine by the genital organs became restored. The idea then immediately occurred to M. Berard of there being a communication between the left ureter and the uterus. According to this hypothesis, the urine secreted by the left kidney would be poured into the cavity of the uterus through the urethro-uterine communication; and, as it is probable that the vesical extremity of the ureter is obliterated, if the uterine orifice becomes obstructed, the urine, no longer being able to escape, accumulates in the ureter, which it distends, and, reaching as far as the kidney, occasions the pain to which we have just alluded. In order to ascertain whether the quantity of urine that passed was the same as that which accumulated in the bladder, each was collected in a separate vessel, in the following manner:—The bladder having been completely emptied by a catheter, the patient was placed on a close-stool,

(a) [It is, I think, acknowledged by all that cataplasms or poultices are the most disagreeable, the most filthy, and indeed the most disgusting epithems that can be applied to the human body; and when it is considered that, together with these objectionable qualities, they are, from their composition, by no means calculated to produce the effects for which they are applied—effects solely dependent on the heat and moisture they are capable of containing—it is not to be wondered at that they should have been in a great measure abandoned.

A poultice should contain a large quantity of fluid, not in a state of combination, as is the case with linseed-meal and bread, but free, so that it may come into direct contact with the part to which the epithem is applied, and produce the whole of its beneficial, soothing, and relaxing action, and retain its temperature for a considerable time. It should also be clean and light, and free from anything likely to enter into decomposition. It ought not to be bulky, and should admit of being easily retained in its place.

An article answering to this description will, I believe, be now shortly introduced, and, from the numerous successful trials that have been made of it, both by myself and other professional men, I am convinced it will be found a very valuable and effectual medium for applying moist heat, and one far superior to the ordinary poultices and fomentations. In proof of this I may mention the two following cases.

C. E., aged 16, applied for advice, in consequence of a phlegmonous mammary abscess, to a medical man of the neighbourhood in which she resided, who advised bread and water or linseed-meal poultices. She persevered in these remedies for some time; but finding no benefit, and being told that the abscess must break, she became very uneasy. On examining the part, this termination appeared inevitable. I recommended her to discontinue the poultices, and gave her one of the epithems above alluded to, with instructions to saturate it with hot water and keep it constantly applied to the part, taking care to change it once in twelve hours. She called again a few days afterwards and thanked me for having afforded her so much relief. She stated that the epithem was always warm and moist when taken off, and was much more comfortable to the part than the poultices. On examining the breast, I found it considerably reduced in size, much less tense, and the pain greatly diminished. I advised her to continue for a short time longer, which she did, and the abscess entirely disappeared.

In this case I have not the slightest doubt that, had the patient continued in the application of the bread and water or linseed-meal, the abscess must have broken; whereas with this article resolution was speedily effected.

The next was a case of peritonitis. Here, in addition, of course, to other remedies, poultices and fomentations had been applied, and of both of which the patient continually complained. The first, he said, annoyed him by their weight and offensive smell, by the "mess they made him in," and by their so soon getting cold and dry, and requiring to be so frequently renewed; the second he objected to from the constant and necessary repetition of the flannels. I gave him one of the epithems, which he was much delighted with. It was light and soothing to the part, did not get cold or dry, and required changing but once or twice in the day. I might mention various other instances of cutaneous eruptions on the head and face, of bruises, inflammation, abscess, &c., in which this newly-invented material has been used, but the above will be sufficient to prove its advantages and superiority.—TRANS.]

the pan of which was to receive the fluid that flowed from the genital organs. At the expiration of two hours the urine that had collected in the bladder was drawn off by a catheter, and compared with that that had passed by the vagina. The quantity was found to be exactly the same, but that which had remained in the bladder was much darker than that which had passed through the fistula. This experiment was repeated several times, its duration being varied, and always with a similar result.

On the 23rd, in order to ascertain whether the communication exists between the bladder and the uterus, or between the ureter and the uterus, an injection, coloured blue by indigo, was thrown into the bladder, and its escape prevented by placing the finger exactly over the meatus urinarius. By then opening the vagina so as to expose the orifice of the neck of the uterus, we readily convinced ourselves that the fluid which escaped through this passage was not that which had been injected into the bladder, inasmuch as it was perfectly transparent and colourless, and had both the smell and the taste of urine. Two or three spoonfuls were collected, that it might be better judged of.

There exists, therefore, no communication between the bladder and the uterus; and as there is a constant dribbling of urine through the orifice of the neck of the uterus—as the quantity of fluid which thus escapes is always equal to that which collects in the bladder—and lastly, as the patient experiences severe pain in the left kidney whenever the dribbling becomes stopped—it is probable, if not certain, that there is a communication between the uterus and the left ureter, and that the vesical extremity of this passage is obliterated. Not being able to cure this patient, we had made for her a urinal, to be adapted to the neck of the uterus, and kept in its place by means of a curved stem fixed to a truss. This apparatus she could not endure, and therefore was obliged to make use of a common urinal, fixed upon the thigh, and adapted to the vulva. She left the hospital at the beginning of the month of July.

I analysed, on two different occasions, the urine from the ureter that empties itself into the bladder, and that from the one that empties itself into the vagina. Both specimens were collected by M. Triflet, who brought them to me himself. The results of this examination are as follows:—

May 25, 1845.—1st. The urine collected in the bladder is limpid, and of a yellow colour; has a strong smell, a specific gravity of 1·021 at the temperature of 15 deg., and an acid reaction. By evaporation over a water bath, 1,000 grammes were found to yield 37·8 of a residue composed as follows:—Urea, 23·3, uric acid, 0·61; mucus, 0·17; fixed salts, 13·73. This urine contains, besides, traces of hippuric acid which I do not estimate.

2nd. The urine passed by the ureter that empties itself into the vagina is limpid, very light coloured, and has but little smell; its density is 1·015; it is but slightly mucous, and reddens litmus paper faintly. It was carefully evaporated over a water bath, and the quantity of dry residue obtained was in the proportion of 20·25 to 1,000 of urine. This residue was composed of—urea, 12·2; uric acid, 0·14; mucus, 0 1; fixed salts, 7 81. This urine also contained traces of hippuric acid.

June 11.—3rd. The urine collected in the bladder is thick and high-coloured; its specific gravity is tolerably high, namely, 1,025 at the temperature of 15 deg. It has a powerfully acid reaction, and lets fall, on standing, a large quantity of mucus and uric acid, of a reddish-yellow colour. On careful evaporation over a water bath it yielded 46·42 per 1,000 of dry residue, composed of—urea, 30·54; uric acid, 0·86; mucus, 0 42; inorganic salts, 15·30. This urine contained traces of hippuric acid.

4th. The urine passed by the ureter that empties itself into the vagina has but little colour, but contains a tolerably abundant mucous deposit. It reddens litmus paper, and is of specific gravity 1·018 at 15 deg. It yielded 26 90 per 1,000 of dry residue, composed as follows:—Urea, 10 42; uric acid, 0·16; mucus, 0·21; inorganic salts, 12; and traces of hippuric acid.

The results of the preceding analysis prove that the specimens of urine that were examined differed only in the proportion of water they contain; the urine collected in the bladder containing less than that passed per vaginam. This may depend either on a different secretion of the two kidneys, or on a special absorption by the orifices of the veins arising from the bladder. This opinion appears to be much the more probable one, and is founded on an experiment, the results of which I will now briefly relate.

I injected 2 grammes of prussiate of potash, dissolved in 20 grammes of water, into the bladder of a strong male rabbit. A strong ligature was afterwards placed round the penis so as to prevent the urine from escaping. Two hours afterwards the rabbit was killed by opening the carotid artery. A solution of persulphate of iron placed over the course of the principal veins of the abdomen produced, by its absorption, a very evident blue colour. The same re-agent also produced a blue colour when poured on the internal surface of the heart. This effect, however, was not so sensible in the serum of the blood. Notwithstanding this latter result, it appears to me evident that the prussiate of potash was absorbed and carried into the blood. And considering the results of the foregoing case, and those of the experiment I have just related, we may, I think, conclude—

1. That the urine that enters the bladder, and remains there a greater or less length of time, is partially absorbed.

2. That the portion which is absorbed is richer in water than that which remains in the bladder, and which becomes more and more concentrated.

In a hygienical point of view it is of great importance to retain the urine in the bladder as little as possible; and it has been remarked by the old observers that this is more particularly indispensable when the perspiration, after having been very abundant, becomes suddenly checked. In this case, to retain the urine in the bladder would be, they say, to expose ourselves much more to the various accidents and diseases that occur after sudden chills and suppression of the perspiration.

19, Langhalm-place.

ON CHOLERA.

By EDWARD MONKS, Esq., Surgeon.

Cholera, cholera European, sporadic cholera, or choleric diarrhœa, are the names which we apply to the following collective symptoms, viz.: vomiting and purging, with great prostration of the circulatory and nervous functions, attended with cramps, &c., occurring as a sporadic or epidemic malady.

The vomiting is frequent, and often the most troublesome and persistent symptom, all fluids received into the stomach being soon rejected, the vomited matters being a thin muco-bilious-looking fluid, or a thin coffee-ground-looking fluid.

The diarrhœa consists of a thin, copious, dirty, or greenish-looking pea-soup discharge, often very offensive; or a pale gruelly-looking fluid, and then with little or no fæcal odour; at times the discharge contains a quantity of a bottle-green admixture; in many cases the diarrhœa is arrested while the vomiting is urgent, or *vice versa*.

The Collapse, or dangerous Prostration of the Circulatory and Nervous Functions. Here you have a small feeble pulse; often not perceptible pulse at the wrist; a general sub-heat of surface; the extremities being cold, clammy, and of a leaden-blue colour, from venous capillary congestion.

The expired air is of a sub-heat, or cold; the tongue is moist, cold, paler, and perhaps furred; the aspect collapsedf or sunken, being of a grey or venous-like pallor, with blue lips, and a sunken state cellular tissue beneath the inferior eyelids, which latter are also of a bluish grey or leaden tint. The patient complains of the feeling of heat all over, notwithstanding the external reduction of temperature, and endeavours to throw off the clothes, to lie as much as possible uncovered. There is an intense thirst and a constant desire for cold water, which desire is no sooner gratified than it is again vomited, and the desire is as urgent as before. The breathing is quicker and shorter, and chiefly thoracic, with a sense of weight or constriction across the chest. The pupils are natural, or slightly contracted, and the mind unaffected. There is a restlessness and anxiety, with an occasional deep sigh and a disposition to sleep; but the patient is unable to do so, and the eyelids remain only partially closed during this short seeming disposition. The voice is faint and whispering; the urine, is suppressed in some cases, diminished in most with at times detention. The cramps mostly complained of are those of the abdomen and calves of the legs.

Treatment.—With a view of relieving the vomiting, cramps, &c., the following draught answers best in my hands:—

℞. Sp. æther. nit. ʒj.; [illegible] ℈j. vel [illegible]; tinct. opii. *m.* xx.; aquæ aromat. ad ℥j. M. [illegible] should be added to ℥ss. of hot water, and given immediately, after which a warm mustard cataplasm should be applied to the abdomen or back, which should be allowed to remain on about ten to twenty minutes, or until a degree of pain or redness follows.

Heat also should be applied to the feet by the means of hot water contained in bottles or some metallic vessel; and, if my patient does not object, I employ in addition the following enema:—

℞. Tinct. opii *m.* xx.; potassæ chlorat. ʒj; creosoti *m.* ij.; aquæ aromat. ʒj. M. To be added ℥x. of warm beef-tea, or some mucilaginous vehicle, and used as an enema. If there be very great collapse I add ʒij. of the oleum terebinth. to the clyster.

The above means being employed are followed by the most happy results; and, in many cases of dangerous choleric diarrhœas or collapse, even in a few hours, or by the following day, a convalescing state is evident. If, however, on your next visit, which should not be protracted beyond eight or twelve hours, and you find your patient still in collapse, or only partially rallied, and the vomiting still troublesome, you must now give gr. j. of calomel every hour (or every two hours), which should be washed down by only two tablespoonful quantitus of warm wine and water, arrowroot, or wine and beef-tea, in the proportion of about ℥ij. of wine to ten of the before-named fluid, and repeat the enema, cataplasm, and calor pedibus.

The above line of treatment, with such modification as individual cases suggest, is that which has proved very successful in my hands, and I do, therefore, confidentially recommend it to my professional brethren, to which I desire to add the following observations.

Ammonia *does not* prove a useful medicine in these cases, and seldom indeed in other cases in which vomiting or diarrhœa is an urgent symptom. The sp. æther. nit., potass chlorat., and t. opii *are* the best stimuli.

Cold water, or large quantities of fluid, indulged in, with few exceptions, add to the danger of the patient, or at least my first cases so indulged ended in more deaths than recoveries; the thirst, vomiting, or diarrhœa and collapse, were more or less increased by it.

A fuller pulse, a return of natural warmth, with a disposition to sleep, and less urgent thirst, are among the earlier symptoms of recovery.

To youths about fourteen about half the quantities of the several therapeutics named may be given, or even the same doses I occasionally employ.

During the convalescing periods, draughts, containing the sp. æther. nit. and potass chlorat. in an aromatic water, are sometimes useful.

Beef-tea enemata, with or without medication, are, I am sure, a valuable means of rallying the vis vitæ, by its mechanical influence upon th viscera, as well as by its dietetic properties.

Friday, P.M., Sept. 4.

The following gentlemen have been appointed Chevaliers of the Legion of Honour:—M. Salleson, Surgeon-Major of the Ambulances in Algeria; Dr. Santi, Assistant-Surgeon of the First Class to the Ambulances in Algeria; Delpecq, Assistant-Surgeon of the First Class to the Ambulances in Algeria; Lebrun, Assistant-Surgeon of the Second Class to the Ambulances in Algeria.

HOSPITAL REPORTS.

MEDICAL TIMES PRIZE REPORTS.

THIRD SERIES.

Reported by WILLIAM ANDERSON, Esq., Student at St. George's Hospital.

MEDICAL CASES.

SUBJECT—DROPSY.

CASE I.—Thomas Silk, aged sixty, shoemaker. Admitted May 21, 1845. Under Dr. Nairne. [illegible]; tongue white and moist; bowels con- [illegible]gh-coloured; pulse 96, full and [illegible] much swollen; has had a cough [illegible]toration for two months; has no [illegible] and can draw a deep breath without [illegible] began to swell six weeks ago. Ordinary diet.

℞. Pulv. jalapæ C. ℈ij. o.m.; cat. sinapis thoraci; mist. oxymellis scillæ, ℥j. 6tis horis.

24. Less swelling in legs; large crepitation at [illegible]er part of left lung; snoring; rhonchus under [illegible]ht clavicle; there is a loud valvular murmur.

℞. Pil. digitalis C. gr. v, ter die.

Haust. sennæ, ℥iss. statim. Omit pulv.

26. Has still a good deal of pain in the chest; does not make much water. Cat. sinapis pect.; spirit. genevæ, ℥ij.

27. Pain in chest relieved; makes more water.

29. Better; makes a good deal more water, can lie down at night; legs less swollen.

31. Makes more water; less swelling; breathing difficult.

June 1. More difficulty of breathing; coughs much; less swelling of legs; cannot sleep.

℞. Haust. morphiæ c., oxymell. scillæ, spir. ætheris nitrici aa. ʒj. o.n.

3. Breathing better, but still difficult; complains of fluttering in left side. Cat. sinapis regione cordis.

5. Feels better; cough easier.

7. Breathing easier; makes more water; legs much less œdematous.

10. Gums affected by the mercury; still troubled with hacking cough. Omit. pil.

℞. Potassæ. bitart. ʒiv. cras et o.n m.

12. Has still a good deal of cough, but is otherwise better; swellings nearly gone

14. Makes plenty of water; bowels open; swellings have entirely disappeared.

17. Went out relieved.

CASE 2.—Elizabeth Campion, aged fifty-three; married; eight children.

Admitted August 14, 1845. Under Dr. Nairne.

Feels thirsty; appetite bad; bowels open; pulse 96, sharp, not easily compressible; complains of palpitation of the heart; there is excessive dyspnœa, and she has not been able to lie down in bed for three weeks; respiration quick and oppressed; has had difficulty of breathing only five or six weeks; has often had rheumatism (chiefly in right leg and hip); the legs are much swollen, and the abdomen is said to be so, but is not in that state at present; she complains of pain across the lower part of the chest, chiefly on the left side; and she has a slight cough. Ordinary diet.

℞. Mist. camphoræ, ℥j.; liq. ammon. acet. ℥iss.; tinct. hyoscyami, m. xxx.; spir. æther. nit. ʒj. ter die.

℞. Haust. morphiæ, ʒxj.; spir. æther. nit., ʒj. o.n.

15. Has had no sleep; pulse 100, sharp and jerking. Emp. belladonnæ pect.

16. Specks of bloods in sputa. Catap. sinapis.

℞. Ext. hyoscyami, gr. v., o.n. Omit. haust. morphiæ.

17. Much relieved by mustard poultice; complains now of great pain between the shoulders; has cold perspirations; feet and hands very cold. Catap. sinapis. int. scap.

℞. Spir. æther. s.c., m. xxx.; mist. camphoræ, ʒxj.; tinct. lavandulæ. c. m xxx. stat.

℞. Haust. sennæ, ℥js. cras.; spir. vin. gall. ℥js. subinde.

18. Pulse 84, full, not easily compressed; has spit up a good deal of blood to-day; tongue brown and dry; pain in region of heart in drawing a deep breath; feels composed and relieved by the draught. Cat. sinapis sterno.

℞. Potassæ nitratis, gr. x; spir. æther. nit.; spir. juniperi, aa. ʒj.; aquæ distill., ʒix.

19. Has had no sleep last night; seems sleepy this morning; breathes more easily.

20. Much the same.

21. Had a bad night, is sleepy this morning; has violent pain in the chest.

22. No sleep; excessive dyspnœa

℞. Haust. opiates, ℥js.; spir. æther. s.c., m. xx. o.n.

The dyspnœa continued unrelieved; she spat up a considerable quantity of blood, and died suffocated in the evening.

SECTIO CADAVERIS.

Body well formed, but spare; anasarca of the lower extremeties.

Thorax.—A small quantity of fluid in the pericardium; heart much enlarged by dilatation of all its cavities, especially those of the left side, the walls of which were somewhat thinner than natural. Tricuspid, mitral, and pulmonary valves healthy; aortic valves thickened, contracted, and extensively adherent to the walls of the artery. The whole of the thoracic aorta was dilated, especially at its arch, where it formed a kind of pouch. The internal surface of this vessel was roughened by an extensive deposition of atheromatous patches throughout the greater part of its extent. The cavities of the heart and all the vessels were extensively blood-stained. The coagula contained in these parts were large, firm, and of a very dark colour. Some fluid, of a dark colour, was found in the cavities of both pleuræ, but there was a much larger quantity in the right than in the left. The right lung contained several patches of pulmonary apoplexy, one of which, a very large one, was situated at the back part of the inferior lobe. The posterior part of this lung was loaded, with the exception of the apoplectic patches, with large quantities of red, frothy serum; its tissue was soft and easily torn. The whole of the posterior part of the left lung was also loaded with large quantities of red, frothy fluid, and also contained some patches of an apoplectic nature. The anterior part of both lungs was healthy.

Abdomen.—A small quantity of dark-coloured bile-tinged fluid was found in the cavity of the peritoneum, the capsule of the liver was opaque and slightly thickened, but the tissue of the organ appeared healthy: it presented venous hepatic congestion of the second degree to a great amount. The other viscera presented nothing remarkable.

CASE 3.—Wm. Brinkworth, aged 27.

Admitted March 20, 1845. Under Dr. Nairne.

Pulse 84, sharp; bowels confined; urine tolerably free and highly albuminous; sleeps well; tongue pretty clean.

There is great œdema of the whole body, especially of the penis, scrotum and lower extremities; there is some cough and crepitation in the chest; there is no pain, but a sensation of fulness in the chest, which interferes with respiration; this came on suddenly ten weeks ago, before which time he was perfectly well, and has increased ever since; sounds of the heart are natural. Fish diet.

℞. Pulv. jalapæ C. ʒss. o. m.

27. Much the same; V. S. ad. ʒxij.

℞. Infus. digitalis, ʒiv.; tinct. scillæ, m. xv.; spir. æther. nit., ʒj.; potas. acet., ℈j.; aq. menthæ virid., ℥vjss. ter die.

28. Bowels not open.

℞. Olei ricini, ℥ss. statim.

29. Had a rigor last night, and another this morning.

30. Bowels not open; urine scanty.

℞. Pulv. jalapæ C. ℈ij. cras.

April 1. Face less swollen; bowels quite open; watery motions. Ordinary diet.

Rep. pulv. o. a. m.

3. Much the same.

Rep. pulv. o. m.

5. Rather more colour in the face; swellings no less; urine very scanty.

℞. Ext. colocynth. C. gr. vij.; ext. scillæ, gr. ij.; hydrarg. chloridi, gr. j. o. n.

8. Bowels open twice a day; motions watery; the left hand is more œdematous; complains of feeling very tight.

10. Makes no more water; the swelling of the right arm and hand is increased. To have six acupunctures in the abdomen.

12. A great quantity of clear fluid has oozed from the punctures, which have given great relief; the thighs and legs are still enormously swollen, and the skin very tense; urine very scanty, and more than half of it appears to consist of albumen.

℞. Potassæ bitart., ʒvj. o. m.

13. Bowels not open; the thighs and legs more painful from tension. To have twelve acupunctures made in the thighs.

℞. Pil. colocynth. c. hyoscyamo, gr. x. M. Rep. potassæ bitart.

14. Has been sick to-day; the last punctures have not discharged so much as those in the abdomen. Beef-tea and arrowroot, milk, ℈j.

16. Complains of pain in both sides of the chest in coughing; cough most troublesome in the evening; feels thirsty; makes rather more water.

Emp. lyttæ lat. thor. utraque.

℞. Haust. salini c., ant. pot. tart. gr. ¼; 6tis horis.

℞. Ext. colocynth. C. gr. x.; olei tiglii, m. j. o. s. m.

19. The pain much relieved by the blisters, which have discharged a great deal; the body and face less swollen; feels sick after taking the pills; bowels well open; motions watery.

Rep. mist. Mutton chop. Rep. pil. sine ol. tig.

22. Cough very troublesome at night, and accompanied with a large quantity of expectoration; urine less; bowels open well. Omit. pil.

Rep. Mist.; pulv. jalapæ, C. ℈ij. o. n.

There is great mucous crepitation heard over greater part of the chest.

26. Bowels open; has been sick this morning.

29. Coughs much less; bowels not open.

℞. Ext. jalapæ, ext. colocynth. C. aa. gr. v. o.n.

May 1. Complains of great soreness of scrotum, the skin of which is chafed by the bedclothes, and discharges much watery fluid. Videat. chirurg. de scroto.

3. Feels more comfortable, and not so tight; swellings of the legs and body are diminished; bowels opened freely by the pills without griping.

6. Complains of much tightness and tension of legs; bowels open about four times daily; legs to be punctured again.

8. Makes more water, but complains of griping in the bowels after taking the powder; the legs discharge freely from the punctures. Omit. pulv.

10. More comfortable; swellings less; bowels open; makes more water; griping in bowels has left him. Roast slice.

13. Feels easier; makes more water; bowels open; swellings diminishing.

15. Cough rather troublesome; the calves of the legs are rather red and tender from rubbing against the bedclothes.

17. Does not feel so well, and complains of a sensation of pressure in the right side of the chest; bowels not so open. Olei ricini, ℥ss. statim.

20. Complains of a sensation of pressure in the right side of the abdomen, where the skin is very tense from the œdema; bowels open only twice; makes less water. Omit. pil.; twelve acupunctures to be made in the abdomen.

℞. Pulv. jalapæ C. ℈ij., o.m.

24. Coughs very much; is troubled with sickness, and griped very much. Haust sennæ, o.n.; loco pulv.

27. Still very sick; bowels very open; makes less water.

29. Sickness still continues; bowels open.

Rep. haust sennæ. Rep. pil. colocynth. C. jalap. o.n.

30. Sickness has left him.

31. Bowels very open; motions watery; makes less water, which is highly albuminous.

June 3. Has had no return of sickness; bowels well open; stools not so watery.

Rep. pil. iij. o.n.

Spir. vin. gal., ℥ij. quotidie.

5. Feels a pain in the left lumbar region; bowels very open; motions very watery; face not quite so white.

7. Complains of tightness across the chest; has less expectoration; makes less water; bowels open.

10. No return of sickness; pain in side returned.
12. Bowels confined; feels tightness of abdomen. Beef-tea.
℞. Haust. sennæ, ℥jss. statim.
℞. Elaterii, gr. ½ in form. pil. o.m.
Rep. spir. vin. gal. Omit. m̄ia.
14. Bowels have not acted until to-day, when he took haust. sennæ, ℥jss.
℞. Elaterii. gr. ss. o.m.
17. Purged well; does not feel quite so tight in the abdomen.
21. Bowels confined; swellings increasing. Haust. sennæ, ℥jss. statim.
℞. Elaterii, gr. j. o.m.
24. Has watery motions; feels a little easier.
26. Pill sometimes produces sickness; is purged freely.
28. Very sick; abdomen much softer.
Rep. pil. o.a.m.
July 1. Continues vomiting for about two hours after the pill.
2. Still vomiting as before. Omit. pil.
3. Sickness has ceased.
℞. Ext. jalapæ; ext. colocynth, a.a. gr. v. o.n. Haust. sennæ, o.a.n.
5. Is rather griped.
Rep. pil. et haust. adde sing. haust. spir. myristicæ, ʒj.
8. Feels better; says "he feels more himself," but is very weak.
℞. Haust. cinchonæ, ℥jss.; acid. sulph, dil. ♏. xv. bis. die.
10. Appetite better; feels a little stronger.
12. Much the same.
15. Makes more water, but feels very tight, especially up the right side. Twelve acupuntures to be made in the part complained of.
17. A large quantity of fluid runs away from the punctures; cheeks and hands more swollen; a slight erythematous blush on the left side of the abdomen.
18. Fluid still continues to flow from the punctures; bowels not open. Olei ricini, ℥ss. statim.
19. Face and hands much more swollen; legs and body less tense; fluid is still flowing; left side of abdomen is very tender; feels very drowsy, and is very hungry.
Rep. haust. ter die. Extra diet.
Rep. Olei ricini, si opus sit.
22. The redness on the abdomen has disappeared; abdomen much more flaccid; fluid has ceased to flow; bowels freely open; very weak. Vini Xerici, ℥jv. Omitte spir. vin. gal.
24. Face much less swollen; arms still much swollen; complains of tenderness of abdomen.
26. Has vomited this morning; has more colour in his face; bowels regular; takes oil occasionally; the pills failing to act. Omit. pil.
Rep. olei ricini, o.a.m.
29. Vomiting continues; he is not so drowsy; has cough, with slight expectoration; less swelling of hands and face; abdomen getting tight again; bowels not open.
℞. Potassæ bitart, ʒjv. o.m.
31. Seems very weak after the powder; cough worse.
℞. Potassæ tart., ʒjv.; haust. pimentæ, ʒxj.; spir. myristicæ, ʒj. o.m.
Rep. haust. cinchon. et vin.
August. 2. Last night he was seized with severe pain low down in the right side, extending up to the shoulder; increased by deep inspiration and coughing; great pain on pressure over ribs; was ordered poppy fomentations and opium draught, which sent him to sleep; the pain is very acute this morning, obliging him to take very shallow inspirations. Pulse 120; bowels open. Hirudines, xviij. lat. dext. Omit. mist.
Rep. Haust. opiat. h.m.
℞. Pil. hydrarg., gr. iij.; opii, gr. ¼.; pulv. scillæ, gr. j. 6tis horis.
3. Passed a good night; pulse 84, weaker; tongue cleaner; bowels open; pain much relieved; cough worse. Emp. lyttæ lat. thor. dext.
4. Very sick; still a little pain in the right side on deep inspiration; blister rose well; gums rather tender; makes more water; bowels not open.
Rep. oleum ricini cras.

5. Bowels have not yet acted; still very sick and drowsy.
Rep. olei ricini, ℥ss.
6. Mouth sore; makes plenty of water; still a little pain on deep inspiration; still sick; very weak. Omit pil. Arrowroot.
7. No pain in chest; bowels open; no appetite; swellings legs; mouth less sore.
℞. Haust. cinchonæ, ℥jss.; acid. nit. dil. ♏. xx. bis die.
8. A little return of pain in the chest; bowels not open; still sick.
℞. Acid. nit. dil., ♏. xx.; tinct. lavand. C. ♏ xxx.; aq. distill., ʒxj. ter die.
11. Retains the medicine; bowels well open; throws up the arrowroot. Roast slice.
12. Bowels open; still sick. Spir. vin. gal. loco vini.
16. Much the same.
℞ Pil. gambogiæ. C. gr. x., o.a.n.
19. Bowels not open; constant sickness.
℞. Mist. camphoræ, mist. ferri C. aa., ʒvj.; pulv. jalapæ C. ℈ij., o.a.n.
20. Powder makes him sick. Omit. pulv.
℞ Ext. colocynth C.; ext. jalapæ, aa., gr. iv.; ext. hyoscyami, gr. ij. o. n.
21. Bowels have not been open for three days; integument of right leg has given way and discharges freely.
Rep. pil. nocte maneque. Enema catharticum statim.
23. Right leg discharges from the front of the knee and lower part of the calf; bowels confined.
℞. Decoct. aloes C.; inf. sennæ, aa., ʒvj., o. m. Omit. pulv.
26. Constant sickness; bowels not open. Omit. mist.
℞. Pil. aloes C.; ext. colocynth. C., aa., gr. v., o. m.
28. Very sick; bowels confined. Olei ricini, ℥ss. stat.
30. Leg discharges a great deal. P.
Sept. 2. Was seized with excessive difficulty of breathing in the night; coughs and spits frequently; face shrunk; is very drowsy; bowels not open to-day. Cat. sinapis. thor.
℞. Spir. æther. s. c.; tinct. lavandulæ c. aa. ʒss. mist. camphoræ., ʒxj. ter die.
3. Breathes more easily.
4. Much the same. P.
7. Breathing became more laborious, and he died at eleven A.M. The friends would not allow the body to be examined.
Case 4.—Charlotte Brookes, aged twenty-three, dressmaker.
Admitted August 15, 1845. Under Dr. Nairne.
Tongue pale and dry; pulse 96; good strength; feels thirsty; bowels generally confined; does not make water freely; there is ascites and anasarca of both legs; she complains of pain in the head; pupils dilated; sees very badly; feels uncomfortable when lying down; pain in head worse at night and when she wakes; appetite bad; legs began to swell eight months ago; abdomen was a little swollen, but has increased a good deal in the last three weeks; dimness of sight came on ten months ago; urine acid, pale and highly albuminous. She left the hospital three weeks ago, having been in for seven weeks.
℞. Mist. ferri C.; mist. camphoræ aa., ʒvj. ter die; pulv. jalapæ C. ʒss., cras mane.
16. Pulse 96, feeble.
19. Abdomen less swollen; contains more flatus than fluid; feels better; makes plenty of water; has taken the powder every morning.
℞. Mist. ferri C., ℥j. ter die.
Rep. pulv. o.a.m.
21. A little less swollen; does not make so much water; has been very sick.
Rep pulv. tertiâ quaque mane.
23. Has the globus hystericus occasionally; breathing short; does not make much water.
℞. Potass. bitart., ʒjv. o.a.m.
25. Feels very low; has great pain in the epigastrium; pulse weak; feet cold; no appetite; sick incessantly, bowels confined. Spir. vin. gal., ℥ss. subinde. Cat. sinapis epigastrio. Omit. pulv. Olei ricini, ℥ss., si opus sit.

26. Worse; pulse feeble; bowels open; countenance anxious; breathing short. Vini Xerici, ℥iv. Loco spiritûs vini gallici.
℞. Spir. æth. s. c., ♏. xx.; spir. lavand., ♏. xl.; aq. distill., ʒxj. ter die.
27. Feels better; makes very little water; bowels open.
28. Had a morphia draught last night; slept better; pulse rather stronger; no appetite; strong beef-tea.
℞. Haust. salin., ℥jss.; pulv ipecac. C. gr. v. o. n.
30. Great difficulty of breathing came on in the afternoon, which continued till the evening; faculties entire to the last. Died at ten P.M.

Sectio Cadaveris.

General Anasarca of the Whole Body.

Abdomen.—The peritoneal cavity contained a very large quantity of serum, of a dark yellow colour; both kidneys were much increased in size and in weight. The cellular tissue round the capsules of these organs was condensed, and firmly adhered to them, so that it was difficult to separate it from them. The cortical structure in both kidneys presented well-marked specimens of mottling degeneration, and their surfaces were granular. The disease in the left kidney appeared to be somewhat more advanced than it did in the right kidney. In the calices of both kidneys were several small calculi and some sand, and the mucous membrane lining these parts was inflamed. The peritoneal covering of the liver was thickened and opaque, and the edge of the liver was thickened and rounded off. Venous hepatic congestion of the second degree existed to a great extent. The spleen was of its natural size, but congested and hard. Uterus and ovaria were natural. Intestinal canal healthy.

Thorax.—Large quantities of yellow-coloured serum were found in the cavities of both pleuræ; both lungs were towards their posterior part loaded with large quantities of red frothy serum, and in the lower lobes there were several patches of red hepatization; these patches were greater and in a more advanced stage of hepatization in the right than in the left lung. Pericardium distended with yellow-coloured serum; heart enlarged by hypertrophy of the walls of the left ventricle; valves healthy; slight atheromatous patches at the root of the aorta, immediately above the valves; large loose coagula of blood, for the most part fibrinous, in the right cavities; small loose fibrinous coagula in the left. Cranium not examined.

Case 5.—Joseph Dean, aged thirty-four, baker.
Admitted June 21, 1845. Under Dr. Nairne.
Tongue white; pulse 84; skin cool; bowels open; motions white; urine scanty, and of a deep saffron colour, staining his linen yellow; skin and conjunctiva of a greenish-yellow hue; appetite pretty good; complains of pinching pain just above the umbilicus, which comes on towards evening and continues all night, but during the daytime he is tolerably free from it; the abdomen is much swollen, with evident fluctuation, a dull sound being given out at the upper part; the feet and ancles are œdematous; there is occasional itching above the umbilicus; he sleeps badly, and has fallen away for the last eight months; has no cough, but is troubled with wind in the stomach and acid eructations; eight weeks ago he first experienced pain in the abdomen accompanied with vomiting; in a few days the skin became yellow; about six weeks ago the abdomen began to swell, and three weeks afterwards the feet became œdematous; for the last twelve months he has had occasional pain in the region of the liver.
℞. Pil. hydrargyri, gr. iij.; scillæ contritæ gr. j. ter die.
℞. haust. opiatus c.; spir. æther. nit. ʒj. o. n.
22. Slept well; has less pain in the abdomen; bowels well open.
23. More pain in the abdomen; passed a bad night; makes more water, which is of a dark colour.
Rep. haust. omni nocte et mane si opus sit.
26. Pain in the abdomen very bad at times; urine very dark-coloured; motions white; bowels regular; he has not required the draught in the morning.
27. Vomited this morning.

28. Somewhat better; urine not so dark; still vomits occasionally. Fish diet.

July 1. Vomiting has ceased; seems more cheerful; makes very little water; motions of darker colour.

Haust. seunte cras.

2. Very weak; has no appetite; bowels not open; is troubled much with wind; gums rather sore. Omit. pil.

℞. Olei ricini, ℥ss.; ap. menthæ pip. ℥j. statim.

3. Abdomen more swollen; still sick; bowels well open; motions of darker colour. Beef-tea.

℞. Pulv. jalapæ c. ℈j. o. m.

5. Abdomen blown up with flatus; pain increased after meals; makes more water, which is not so high-coloured; bowels well open.

8. Much more emaciated; still has occasional vomiting; makes less water; bowels well open; no complaint of pain in the abdomen; œdema of legs extending higher up; is very weak.

Spir. geneveæ, ℥iij.

10. The abdomen is more swollen, there is no tympanitis at the upper part; bowels open; no appetite; pulse very irregular. Mutton chop.

12. Still vomiting; bowels not open; only has occasional fits of pain in the abdomen.

15. Bowels confined; is much emaciated; countenance haggard.

℞. Olei ricini, ℥ss. cras et p. r. n.

17. Still vomits; the matter brought up is of a dark green colour.

19. Abdomen much distended; there is more swelling of the legs and thighs; he is very weak; has no appetite, and his countenance is dreadfully sunk. Vini rub., ℥vj. loco spir. gen.

22. Complains of great pain and tightness across the abdomen, which is painful on pressure; tongue red and glazed; sordes on teeth; bowels not open. Takes nothing but the wine.

Half-past ten P.M., died.

SECTIO CADAVERIS.

Thorax.—Universal adhesions of the pleuræ on left side of chest, not of recent formation, but easily separable; left lung healthy, slightly congested at the posterior part; some old adhesions at the anterior part of the right side of the chest; right lung healthy, also congested at the posterior part: heart small; coagula in right ventricle.

Abdomen.—The peritoneal cavity contained a large quantity of dark brown coloured fluid, tinged with bile, with some loose flakes of lymph floating in it. Stomach much contracted, especially the right half, from extensive scirrhous deposit in the subperitoneal cellular tissue. Intestines contracted and drawn together from the same cause; but here the disease was deposited in tubercles, instead of implicating the whole of the cellular tissue surrounding the gut, as in the stomach where the parts had become much thickened. The omentum was drawn up and converted into a scirrhous mass, exactly resembling the stomach. The peritoneum covering the liver was similarly affected; and the cellular tissue around the duct, and the gall bladder itself, were considerably thickened, preventing the escape of bile or its entrance into it. Gall bladder much contracted. Liver larger than usual: the ducts were much dilated and full of watery fluid tinged with bile. Spleen very small. Peritoneum much thickened. Mesenteric glands universally affected with deposits of scirrhous matter. The whole surface of the peritoneum was much thickened, and in the region of the bladder it was nearly a quarter of an inch thick from the same cause.

CASE 6.—Hannah George, aged thirty-eight; married.

Admitted June 18, 1845. Under Dr. Nairne.

Skin cool; tongue clean; bowels open; appetite bad; sleeps well.

She was in the hospital three months ago under Dr. Nairne, when six gallons of fluid were drawn off from the abdomen, which is now again enormously enlarged, very tense and hard, fluctuation being plainly perceptible; there is drawing pain in the groins; general health good.

June 20. Mr. Tatum drew off forty-nine pints of a thick, gelatinous, straw-coloured fluid, exceedingly tenacious, from an enormous cyst in the left ovary.

℞. Tinct. opii, ♏. xx.; spir. æther. s. c. ♏. xx.; mist. camphoræ, ℥xj. statim.

21. Slept well; no tenderness of abdomen; bowels not open.

℞. Olei ricini, ℥ss. cras mane si opus sit.

24. Feels very weak; bowels open. Ordinary diet.

℞. Infus. cascarillæ ℥xjss.; acid. nitrici dil. ♏. xx.; spir. æther. s. c. ♏. x. bis die.

26. Getting stronger; complains of some pain in the right lumbar region, increased by pressure. Fotus abdom.

28. Still pain in the right side of the abdomen; tongue clean. Rep. fotus.

July 1. No pain or tenderness of abdomen.

To go out relieved *pro tem.*

SURREY DISPENSARY.

INFLAMMATION OF THE BRAIN.

William Pyne, aged five, residing in Great Guildford-street, was admitted under the care of Dr. Aldis, March 3d, 1846. Pulse quick; tongue dry, not protruded; bowels open to-day and yesterday; pupils contracted; keeps raising his hands to the head; constantly screaming and moaning; deafness; attacked with vomiting two days ago; afterwards took some jalap; had a fit; was convulsed, and countenance distorted; four leeches and a blister were applied yesterday, the leeches bled for seven hours; was better after their application; the surface is now cold and the face pale; has taken some grey and white powders; vomited yesterday.

℞. Hydrarg. chlorid. gr. ij.; 2dis horis ad quinque vices.

℞. H. nitri, ℥ss. 4tis horis.

4. Bowels not open; better, and more sensible.

℞. Ol. ricini, ℨij.; terebinth., ℨij.; statim injiciend.

℞. Pulv. aloes, gr. iij.; potass. sulphat. gr. iv., attere bene, vespere sumend; abradat. capellitium. Applic. ung. iodin. C.; emp. vesicat. auribus.

Rep. mistura.

5. Fell asleep about a quarter of an hour ago; skin hot; screams occasionally; still deaf; bowels moved once; tongue clean; only one blister took effect.

Rep. hyd. chlorid, gr. ij., 6tis horis.

Rep. pulv. aloes c. potass. sulphat.

7. Pulse quick; skin hot; tongue clean; bowels open; motion to-day very black; moaning; deafness, head hot; pupils dilated; urine scanty, passed rather more yesterday; mouth tender.

℞. Pulv. colchic., gr. ijss. 6tis horis. Hirud., ij. pone aurem; postea, catap. lini. per horam ¼.

Rep. ung. iodinii, C.

℞. Ol. ricini, ℨj., alt. man.

10. Continues deaf; face flushed; urine very free and abundant; much easier; skin hot; slept comfortably for eight hours last night. App. emp vesicat. pone aures.

Rep. pulv. colchici et ung.

12. Tongue white; bowels open; urine very free; pupils contractile; seems very easy. P.

19. The patient took iodide of potassium until the 28th, when, from a recurrence of febrile symptoms, the nitre was again exhibited. On the 31st a great amendment had taken place; and on the 14th of April the patient attended at the dispensary, the hearing being slightly improved; on the 28th in other respects he had quite recovered. The colchicum was employed in the above case in consequence of the praise bestowed upon it by certain German writers, in cases of hydrocephalus. The urine appears to have become much more abundant during its exhibition.

The "Gazette Médicale de Paris" states that the same state of the system prevails in Holland as in France, and that the cholera has been very prevalent at Amsterdam and Rotterdam. No fatal cases, however, have as yet occurred.

A paper from Constantinople states that the cholera up to the 20th of July had made great ravages in Teheran; one of the Schah's sons had died of the disease, and the whole inhabitants of the city had been seized with terror. The King, the Ministers, and the Court had quitted Teheran; the diplomatic body was about to follow, and all those not then attacked were about to leave the city. The capital of Persia would be completely deserted.

REVIEWS.

The Why and the Wherefore; or the Philosophy of Life, Health, and Disease. By CHARLES SEARLE, M.D. 8vo. London, 1846. Pp. 200.

The author of this work is clearly an oddity, and one very much inclined to think and express himself as he likes. The queer, quaint commencement of the title shows him to be little obedient to the conventional ceremonies of sedate English composition. We rather like this, we are fond of a liberal, free sort of phraseology, when good taste presides over it; but we think Dr. Searle might have made choice of a better form of head-piece for his book. The preface, again, has something original about it; expressed, however, without any cant, or courting of critical favour. "All that I solicit on the occasion," says he, "I have a right to expect—fair play and no favour. The bats and the sharks will doubtless attack me; and brick-bats and mire I am fully prepared to expect will be showered at me; but to these I am invulnerable. Candid criticism and well-authenticated facts I respectfully invite; but to attacks of interested malevolence, or inapprehensive ignorance, I am, in the support of my own bosom, supremely indifferent." This is bold enough, but it has a little of swagger about it. An author should always exhibit something of that humility which is inseparable from a consciousness of fallibility; and, instead of posturizing fistically at the critics, telling them to come on, do their worst, &c., it is in far better taste neither to anticipate nor invite their severity, lest the fact of doing so should be construed into a conviction of deserving it.

This is not the case, however, with Dr. Searle, for his book, in the main, is excellent. There is very little theory about it that is novel, and very few facts that were not known aforetime; and yet, the *tout ensemble* has an air of freshness that makes it as entertaining as it is instructive. This compliment we pay to the industry and ingenuity of the author; but still with a certain degree of qualification, for he sometimes lets his imagination get the better of his judgment, and betray him into error. In many places we find him losing sight altogether of the grand principles of inductive philosophy, and generalizing with much positiveness in the absence of the facts necessary to substantiate his doctrine. Thus, he says, "We perceive or deduce the fact that all disease or derangements of health consist intrinsically and virtually in the disorder or derangement of this the primary organic action, that is to say, that of the capillary vessels and the functions they fulfil." (Pp. xix., xx.) Were we inclined to indulge in severity upon this passage, we should comment at length upon the desirableness of precision in the use of language, and acquaint our author that to *perceive a fact* is one thing, and that to *deduce* is something very *different*. What we chiefly complain of in the sentence is, that there is no foundation whatever for the general law it embraces. Though many, perhaps the majority of diseases, are more or less connected with abnormal capillary circulation, pathology has never yet demonstrated whether this be a *consequence* or a *cause*; and to decide, sweepingly and exclusively, for the latter is to do much more than established facts justify, and, in our opinion, to be very much at variance with probability. Such theory would completely exclude the nervous system and function from any direct influence in the production of disease, and make it completely subservient to the blood and vascular apparatus. This, however, would be to wage a decided war against some of the most important truths of pathology. If Dr. Searle will reflect deliberately upon the phenomena of certain affections of the nervous system, as tic douloureux, tetanus, hysteria, hydrophobia, chorea, catalepsy, and some forms of paralysis, he will see the propriety of not limiting the *fons et origo mali* to the capillaries and the fluid they contain.

Some of the author's observations upon electricity, as an active agent in the production of certain important effects in the living system, are very comprehensive and clear. Here again, however, he is not satisfied with the facts, merely as such, which experiment has provided in proof of how

useful an agent electricity is in our vital frame, but he forthwith comes to the conclusion that man is nothing more than an electrical machine, and the life that is in him is none other than electricity! Because certain electrical phenomena are consequent upon respiration, digestion, and other chemico-vital processes, Dr. Searle infers that electricity is the grand cause of these, and of all the other actions in the living system.

"In conclusion," says our author, "if it be admitted that electricity is evolved by the chemical actions going on in the animal system,—which the evidence adduced and Matteucci's experiments pretty satisfactorily prove, and that electricity is equal to fulfil all the purposes of the nervous power, which numerous experiments establish also to be the case; and that living muscular fibre is the most sensitive of all electroscopes, and that there is an electric discharge in all muscles at the moment of their contraction, as Matteucci has shown,—I will ask whether it be at all probable that Nature, with her universal economy of means, would provide any second agency to fulfil the requirements of what this one alone is quite equal to accomplish; which second power exists only in imagination—there being not a shadow of evidence to prove its existence? And as the 'vital force' of Leibig unites in its manifestations all the peculiarities of chemical forces, and of the not less wonderful cause which we regard as the ultimate origin of electrical phenomena, I may, with the facts adduced, venture to call it by its proper name, and at once affirm it to be what it really is—electricity." (P. 21.)

So, the noblest work of God's creation is a compound of certain atoms and electricity! This is man! At least, Dr. Searle's man! We are humbly satisfied to entertain a different notion of the race of humanity.

Our author's opinion is, that the chief electricity, or *life*, of an animal, is derived from the combustion in his capillary system. Of course, then, the *life*, or *electricity*, of an animal will bear some ratio to his respiratory process, and be ample in proportion as this is ample. Unfortunately, however, for this theory, the *gymnotus*, the most electrical animal known, is cold-blooded, and, consequently, can absorb and apply very little oxygen; whilst birds, whose respiratory apparatus is the largest of any animal for their size, and whose circulation is extremely rapid, and blood amply supplied with oxygen, evolve very little electricity! Our author ought to have known, again, that the *gymnotas*, *torpedo*, and other electrical fishes, are provided with a peculiar nervous apparatus for discharging electricity; and that the disposal of it is at the animal's will. Irritating them, and especially irritating their brain, causes them, in a few minutes, to evolve more electricity than the process of respiration in an eagle would be able to supply in a month! There can be no doubt whatever that the organs that accumulate the electricity are also the organs that *generate* it.

On the subject of mercury, our author is a little at discount:—"Whatever be the preparation of mercury administered," he says, "the condition in which it is received into the stomach I believe to be that of a chloride, seeing that it must be first subjected to the influence of the hydro-chloric acid of the stomach's secretion, and dissolved before it can be received into the circulation." (P. 86.) What, then, does he make of the administration of metallic mercury by mouthfuls, without a single instance being known of its *chloridification* in the stomach? How will he reconcile salivation and poisoning, by sub-sulphate and nitrate of mercury, for he cannot imagine these salts to be decomposable by muriatic acid!! These appear to us to be instances of very unstudied opinion.

We could select sundry more evidences of want of discrimination on the part of our author, but space will not permit us. There are a great many faults in his book, which, perhaps, are more the result of haste in getting it up than of anything else. But we must candidly say that it contains many excellencies of which any man might be proud. No common man could have written such a book; and we hope we have not met Dr. Searle for the last time.

TO CORRESPONDENTS.

A Handsome Portfolio *for holding the* "Medical Times"—*very desirable to those who would keep the numbers clean for binding, and easy of reference—may be had, by order of any Bookseller, or at the Office, price 6s. An allowance is made to the trade.*

S. S. S. H. D. *should apply to Sir William Burnett, the Director-General of the Medical Department of the Navy. The duties are those of assistant-surgeon, and the same qualifications are required.*

C. E V. Goate *is duly qualified according to the last regulations issued by the Poor-Law Commissioners.*

A Retired Practitioner *suggests, in reference to Mr. Smith's case, of wound of the kidney, "that the probe is a dangerous explorer, when not used with caution"; and adds, "that minus the probe, the treatment was judicious."*

J. O. T. A. *expresses his opinion of the matriculation examination of the University of London as follows.—"To cut the matter short, the examination is worthless, and no test whatever." We don't agree with him.*

H. R.—*Any well-informed practitioner will give H. R. the information he requires.*

Erinensis.—*The Apothecaries' Act gives the Society power to prosecute all persons practising as apothecaries in England and Wales, without possessing the Society's licenses; but the Court of Examiners have recently expressed their intention of abstaining from instituting proceedings against gentlemen qualified by examination before any licensing body in the United Kingdom.* Erinensis *must read both Gregory and Celsus. Irish apothecaries are eligible.*

An Old Subscriber.—*The* Medical Times *has not always been under its present management. An* Old Subscriber *will readily admit this fact on comparing the first four volumes with those of later date. The second volume is out of print.*

. R.—*The information may be found in our report of the meeting of the National Institute in our last number.*

Vindex, *on the Marylebone business, is quite illegible.*

Fairplay, *on the same subject, suggests "that Mr. C— probably aspires to a cellar martyrdom," and adds, that "his aspirations are likely to be gratified."*

Pathologicus *animadverts forcibly on the ignorance, or worse, of connecting the disease of the soldier, White, with those arising as the remote effects of injury of the d rims. "In such cases (burns and the like),"* Pathologicus *justly continues, "the mucous membrane of the intestinal tube is always found ulcerated when death occurs at a remote period from the injury, whereas," he continues, "no such change is recorded as having been present in the soldier."*

M. D., Liverpool.—*We think the license is a sufficient qualification for membership of the Institute.*

O. H. *would fall under the regulations previous to 1835, and would require twelve months surgical practice. It would require a column to answer all our correspondent's queries, the basis of an answer being at times wanting.* O. H. *should see our Almanac for 1846.*

Mr. S., *who writes on the Hounslow case, should have given the name of his informant.*

Hibernicus —*The fees for surgery usually rate at three guineas in London. The London schools are a month earlier than those of Dublin. The last day in London is October 8.*

A Naval Surgeon's *remarks are quite true; but is any further proof wanted of the absurdity of the medical testimony?*

M. R. C. S.—1. *We think he can be elected.* 2. *We know of no subsequent statute to that effect.*

The correspondent who sends us Lord Redesdale's speech corrected is thanked.

J. D.—*We believe there is no agent of the National Institute at Glasgow. Communications should be addressed to Mr. Ross, at the Institute's Rooms, Regent-street.*

THE MEDICAL TIMES *is the only Medical Journal published at its own Office, and which is free from the control of all Booksellers and Publishers. Gentlemen may procure it by an order on any Newsman or Bookseller, or it will be sent direct from the Office of the* Medical Times *to Annual Subscribers sending by a Post-office order, directed James Angerstein Carfrae, or an order on some party in town, One Guinea IN ADVANCE, which will free them for twelve; Half-yearly Subscription, 13s.; Quarterly. No number of the* Medical Times *can be fr. except to gentlemen paying in advance.*

THE MEDICAL TIMES.

SATURDAY, SEPTEMBER 19, 1846.

"Regnum tibi cum paraveris sis eo dignus."

The National Institute is established. The meeting recorded in our last number constitutes it a thing *de facto*—an Institution to stand for the future on as sure and independent basis as any of the existing colleges or universities in the realm. Its tenure of life is the strongest known to incorporate societies: its necessity in the first place, its popularity in the second. These qualifications it possesses in plenitude; and, of all the medical institutions we know, is the only one of which so much can be said.

Medical men have found by no very favourable experience that the old colleges do not answer the public need, nor fulfil the purposes of their endowment. The Colleges of Physicians insist on rules and regulations that must for ever keep from their portals the vast mass of the profession. They are governed as though it were a fundamental rule of their charters that they should provide medical attendants only for the aristocracy of our country. To be truly of them is to be at once behind the spirit of the age, and unsuited to the varying emergencies of the public weal.

Of our Colleges of Surgeons not more of eulogium can be pronounced. That in England demands even sterner rebuke. With all the inefficiency, all the negative demerits of the very worst-charactered of its sisterhood, it has shown in the face of day an unprincipled betrayal of its best supporters which can be fortunately predicated of no other corporate body, with which time has made us acquainted.

The general practitioners of Great Britain are, thus not only excluded from all the honours, comforts, and amenities of a respectable collegiateship—but excluded with terms of reproach by men often their inferiors in scientific desert, and under circumstances of gross and unprovoked betrayal.

They made the colleges all they have been; they have erected and supported splendid establishments, which, by a species of legislative juggle, now belong to other people; they have, thus paid in shame as in hard cash—and both in vain—for the trumpery distinction of being connected with colleges sinking into disrepute and annihilation under the very load of their overtopping mediocrity. Is this state of things to be continued? Will the general practitioners be for ever content with feathering nests which they are not allowed to sit in? We shrewdly suspect that this is a sort of game they will hardly like to play longer. Then what remains but to organize in concentrated force, by

themselves, and joining, one and all, hand, purse, and purpose, erect an Institution worthy of a free and enlightened and an independent profession—an Institution which, both in its governmental and educational relations, shall mirror at once the activity and liberality that characterize our age, and place English medicine before Europe in that honourable position among the sciences which English skill has already achieved for so many other branches of mental enterprise?

This is the mission of "The National Institute."

"Ars medica tota est in observationibus."—BAGLIVI.

IN nothing is the science of medicine of the present age more distinguished from that of all preceding ages, than in the accumulation of *facts*. Perhaps we shall never collect these in quantity sufficient to give to medicine a title to certainty or absolute exactitude, because of the many varieties and exceptions to generalities which changeable bodies, such as those endowed with life, necessarily exhibit. The conditions of the inorganic world come within the limitations of a few laws, and these are invariable. The properties of inorganic matter admit of classification, and they can be calculated upon with precision; because, as matter in any shape is indestructible, and in an unorganized form can take upon itself only a certain number of types and characters, these are not only demonstrable and definite, but they are unvarying. Thus, the general properties of inorganic bodies are the same whenever subjected to the conditions or modes of influence under which those said properties first came to be announced. It is a law that, at certain temperatures, water rises into vapour, and maintains its increase of volume and of elasticity; that at other temperatures it continues permanently fluid; and that at others it remains a solid, resistant mass. These facts have been so often confirmed, and, moreover, furnish such evidence of not being capable of exception, that they pass into generalities, and are at last arranged as absolute laws. So it is with the other bodies composing the organic kingdom: in so far as their powers and properties have been examined, they are found to be constant and uniform in their operations. It can always be said of them that they will answer in such and such a manner when placed under such and such circumstances. With the living world the case is altogether different. Everything composing it is subject, not only to the laws which govern the lesser kingdom of nature, but to these, certain others are superadded, which are by no means constant. We see this superaddition in the lowest animals and vegetables, which betray a tendency to change, both vital and chemical, such as is never met with in inorganic bodies. The higher we ascend in the scale of vitality, the more compound becomes the individual, and the more variable and various its functions. In man, these conditions are more fully expressed than in any other living creature; and it is for this reason that every moment of his physical and intellectual existence is one of uncertainty. As one man differs from another in stature, stamina, and intelligence, so do we find as great a dissimilitude in all the functions of which life is made up. A certain organic action may be slow in one individual, and correspondently quick in another; healthy in this, diseased in that; resistant and of long endurance here, weak and shortlived there! These are the things that make a calculation upon human strength, health, and longevity, at the best but a matter of hazard. For the same reason, also, there is no certainty concerning the influence of external agents upon the living frame. What one can endure with impunity, another will die from. Though the statistics of disease and death would seem to indicate something like regularity in the occurrence of these at certain seasons, yet the exceptions, on the other hand are so numerous as to make calculation and tabular comparison of little worth. Nevertheless, it is only by statistical inquiry, and the careful registration of facts, whether uniform or contradictory, that we can ever hope to *approach* to anything like precision in the science of medicine.

It is to this collection of *facts*, as we said at the commencement, that is owing the superiority and comparative certainty of the profession in the present day, over the profession of old. We have more data and better, to go upon, than they had; and it is to be hoped that our successors will find themselves still further advanced than we are in the scale of correct knowledge. To this most desirable end it is necessary that we transmit to them whatever our experience enables us to record, that bears any, the slightest, promise of usefulness. We particularly wish to impress this serious fact upon the mind of the practitioner. In the language of our motto, the whole art of medicine lies in observation. Nothing ought to be taken for granted in it, but all ought to be the result of experience. As knowledge is progressive, however, and as there is yet much to learn in the science and art of healing, it cannot be wondered at that the professors thereof are frequently compelled to fight in the dark. Our readers will remember an old anathema by Voltaire against us, on this score. He represents a physician as a blind man, with a club, contending with disease *in the dark*. He supposes him to strike lustily in all directions, in the hope of hitting his foe. Sometimes, Voltaire says, he does hit him, and then, he is said to have cured the patient; as often, however, he hits the latter, and then it is said that the disease has killed him. No doubt there was a time when this terrible sarcasm suited us: that time was when our profession was ruled and guarded rather by theory, than by practice and fact. We hope that in the present day we less deserve the censure than did those who lived before us; and, for the honour of our calling, we trust that those who come after us will less merit it than we do. We have a right to love our profession, as well for its sake as for our own! Having committed ourselves to its working, it becomes us to labour for it with whatever capability we have. It is a common notion—alas! much too common—that if a man get his living by physic, he need care nothing more about it. We beg to tell all such men, that they are under a contemptible mistake. Were physic like a problem in Euclid,—decided, definite, and incapable of disproof, and a man could maintain himself by demonstrating the fact of this said problem—it need not concern him to prosecute it any further. And this, for the simple reason that there would be a clear boundary to the further advance of knowledge on the subject. But with our profession the case is just the reverse—there is still too much of uncertainty in it to justify any man in a feeling of indifference on its behalf. Only by accumulating evidence, and carefully-registered facts, can it hope to be made better than it is. *Nihil temere credendum, nihil negligendum*, ought to be the leading rule of every man amongst us. Let each and every of us follow out this glorious maxim, and we should soon relieve the science of medicine of the painful uncertainty that at present oppresses it. It can never become *exact*, for the obvious reasons we have pointed out; but it can make much, much nearer approaches to this grand desideratum than it has already made. What it now is, it owes to *recorded observation*; let this be further increased in amplitude and accuracy, and our profession will rise in the selfsame ratio. We have often been pained on listening to the cool indifference with which practitioners will speak of their interesting cases—those, we mean, which confirm or constitute marked exceptions to great general principles. We have heard these serious things talked of as if they concerned only the patient and the doctor for the time being; instead of being regarded, as they really ought, matters of information for the profession at large. Many are the instances we have met with of the fruits of half a century's experience dropping into the grave with the possessor, and affording just as much service to the profession as the breath that last left him. There is a wickedness in this! Knowledge was not given to be concealed or hoarded for individual welfare—it was sent, like sunshine, to fall alike on the evil and the good. He who possesses it has no right to hesitate and wonder whether it will answer this end or that; he ought to know that it was sent to be distributed, and that, whatever the results, it becomes him to scatter it. It would ill suit the husbandman to pause in sowing until he could satisfy himself what the reaping might be.

It does not fall to the lot of every one amongst us to have much to say; it is only a few men who have much to discourse upon that is worth listening to; but, we apprehend, there are not many who cannot tell their fellow-practitioners *something*. It is impossible for a man to go over even a few years of practice without meeting with certain facts that will bear being recorded. If these things occur to him, in this wise, he has no right to keep them! He ought to remember that they are not his own, but given him to use and apply for the benefit of his fellow-creatures. An item of successful practice, told faithfully, is a guide to another to "go and do likewise"—an item of the opposite is a warning to one's neighbour to avoid danger. The road of the profession has many

dark paths in it. Who would grudge a light to a traveller on the same enterprise as himself? To him who would do so, we emphatically hold out the suggestion that he may hereafter be made responsible for the fate of his fellow-creature. We have no love of cases recorded blindfold. Many men leave volumes of manuscript behind them, that finally turn out to be only good for shaving-paper! This is ridiculous! But it cannot fail to happen to a practitioner, at all successful, that he has now and then something to say for his compeers. Let him put this down with all care, honesty, and precision—it may happen that ere long it gets a companion that adds to its character—several of these make an approach to *generality*. This is most valuable; but, if there be only a *solitary fact*, it is a significant something in the great treasury it becomes each and all of us to endeavour to fill. *Non vi sed sæpe cadendo.*

OFFER OF A BRIBE FOR A GOOD REVIEW.

15, Liverpool-street, City.

Edward Miles presents his respects to the Editor of the *Medical Times*, if he sends his work to him, which he has recently published, will it be reviewed in the *next or following number?* E. M.'s reason for inquiry is this: he has been disappointed in some cases; the review has been put off, or else some trifling notice *only* has been taken of it, from which *no extract could be taken*. All E. M. asks for is an immediate, a fair, conscientious, and honest report of it. The title is "Health, Comfort, and Longevity promoted, &c." Sixty pages. £10 will be enclosed.

The principle on which E. M. encloses a trifling sum is because he does not consider it reasonable to suppose that an editor can give up his valuable time without some small remuneration. At the same time E. M. acknowledges it would be more agreeable to his feelings, if it would answer as well, if he engaged for six insertions of an advertisement following the review. In that case the ten shillings which would be sent might be placed to E. M.'s credit.

A word, per return of post, will very much oblige, just to say whether, if E. M. sends the book, it will be reviewed *per very next number of the Medical Times*.

My plan is to take an extract from the review, if it is so favourable to allow me, and to *then* advertise the work.

Thy friend, very respectfully.

ix. month, 16, 46. EDWD. MILES.

THE BRITISH ASSOCIATION OF SCIENCE.

[*From our own Reporter.*]

The officers and council for the present year are appointed as follows:—

OFFICERS AND COUNCIL, 1845-6.

Trustees (permanent).—Sir Roderick Impey Murchison, G.C.St. S., F.R.S., John Taylor, Esq., F.R.S., Treas. G.S., the Very Rev. G. Peacock, D.D., Dean of Ely, F.R.S.

President.—Sir R. I. Murchison, G.C.St.S., F.R.S.

Vice-Presidents.—The Marquis of Winchester, the Earl of Yarborough, D.C.L., Viscount Palmerston, M.P., Lord Ashburton, D.C.L., the Right Rev. Bishop of Oxford, F.R.S., the Right Hon. the Speaker C. S. Lefevre, M.P., F.G.S., Sir G. Staunton, Bart., M.P., D.C.L., Professor Owen, F.R.S., Rev. Professor Powell, F.R.S.

General Secretary.—Lieutenant-Colonel Sabine, F.R.S., Woolwich.

Assistant General Secretary.—John Phillips, Esq., F.R.S., York.

General Treasurer.—John Taylor, Esq., F.R.S., 2, Duke-street, Adelphi, London.

Secretaries for the meeting in 1846.—Henry Clark, M.D., T. H. C. Moody, Esq.

Treasurer to the meeting in 1846.—John Sadlier Moody, Esq.

Council.—Professor Anstead, Sir H. T. De la Beche, Dr Daubeny, Professor E. Forbes, Professor T. Graham, H. Hallam, Esq., Rev. W. V. Harcourt, James Heywood, Esq., Dr. Hodgkin, Eaton Hodgkinson, Esq., W Hopkins, Esq., Leonard Horner, Esq., Robert Hutton, Esq., Sir Charles Lemon, Bart., the Marquis of Northampton, Sir John Richardson, M.D., the Very Rev. G. Peacock, D.D., Dean of Ely, Dr. Roget, Captain Sir James Ross, R.N., Professor J. Forbes Royle, M.D.H., E. Strickland, Esq., Lieut.-Col. Sykes, William Thompson, Esq., H. Warburton, Esq., Professor Wheatstone, C. J. B. Williams, M.D., Professor Willis.

Local Treasurers.—W. Gray, jun., Esq., York; Dr. Daubeny, Oxford; C. C. Babington, Esq., Cambridge; J. H. Orpen, LL.D., Dublin; Charles Forbes, Esq., Edinburgh; Professor Ramsay, Glasgow; William Sanders, Esq., Bristol; Samuel Turner, Esq., Liverpool, G. W. Ormerod, Esq., Manchester; James Russell, Esq., Birmingham, William Hutton, Esq., Newcastle-on-Tyne; Henry Woollcombe, Esq., Plymouth; James Roche, Esq., Cork.

Auditors.—Professor Austed, Leonard Horner, Esq., Lieut.-Colonel Sykes.

PROCEEDINGS OF THE SECTIONS.

SECT. B.—Chemical Science, including its Application to Agriculture and to the Arts.

POLYTECHNIC INSTITUTION.

President.—Michael Faraday, D.C.L., F.R.S.

Vice-Presidents.—Professor Graham, F.R.S., Sir R. Kane, M.D., M.R.I.A., Professer Johnston, F.R.S., Dr. Daubeny, F.R.S.

Secretaries.—Dr. Miller, F.R.S., Robert Hunt, Esq., William Randall, Esq.

Committee.—Professor Rosé, M. Dumas, Professor Oersted, Professor Way, Dr. L. Playfair, Professor E. Solly, F.R.S., J. Prideaux, Esq., Professor W. H. Grove, F.R.S., Professor Schonbein, Professor Forchammer, Robert Mallet, Esq., Henry Osborn, Esq., William West, Esq., F.R.S., Dr. Andrews, Robert Warington, Esq., Dr. Leeson, F.R.S., J. Wilson, Esq., W. Lucas, Esq., Thomas J. Pearsall, Esq., Thomas Ward, Esq., Captain B. Ibbetson, K.R.E., Dr. Percy.

THURSDAY.

Mr. Osborne "On the Action of Water in the Suburbs of Southampton on Lead."

W. West, Esq., F.R.S., now read a valuable paper on stating "The Methods as well as Results of Analyses."

Mr. R. Hunt's "Report on the Actinograph" was then read.

This instrument, intended for registering the amount of chemical influence associated with the solar rays, was exhibited last year at Cambridge, since which time, however, it has undergone some few unimportant alterations. Although the registrations are obtained upon a determinate kind of photographic paper, upon which a constancy of result was expected, it appears that the influence of the solar rays produces not merely a difference in the depth of colour but an actual variety in the colour at different times, which renders it exceedingly uncertain to determine the point of maximum action. Several curious facts connected with the solar radiations during the past summer were mentioned, particularly the peculiar condition of many flowers, in which a very remarkable development of leaves within the flower had been observed, arising from the influence of intense light and heat accelerating the vegetative process, and thus interfering with the reproductive functions of the plant. It was also stated that during the extremely hot weather of June and July practical photographists found the greatest difficulties in procuring any good daguerréotype portraits, notwithstanding the clearness of the sky and the intensity of sunlight. It was observed, during this period, that the actinograph, so far from registering as might have been expected, the maximum power of the actinic rays indicated an influence far inferior to it. If the maximum was represented by 120, the resulting effect during the brightest [illegible]s of June and July never exceeded 100, and o[illegible] tell to 80. This indicated some peculiar absorptive power in the atmosphere, due to some cause which has not been yet observed, and which, in all probability, materially influences many meteoric phenomena, and some of the great principles directing the processes of organization and life. The importance of endeavouring to arrive at the laws of this interference was pointed out, and the attention of philosophers called to the numerous curious facts developed by the agency of the discovery of photography, but which, up to the present moment, are without even a theoretical explanation.

"Notices of the Progress of Experiments on the Influence of Light on the Growth of Plants," by Mr. Hunt.

SECT. E.—Physiology.

This section held its meetings in the large room of a vacated old house in Bugle-street. The apartment was commodiously provided, and was attended by nearly a hundred persons, notwithstanding its being separated by the distance of nearly a mile from the scene of the other discussions. The following is the "administration":—

President.—Professor Owen, F.R.S.

Vice-Presidents.—Sir James Clarke, F.R.S., Dr. Roget, Dr. J. Forbes, Dr. Fowler.

Secretaries.—Dr. Sargent, Dr. Laycock, C. P. Keele, Esq.

Committee.—Sig Matteucci, Dr. Clark, Dr. J. Bullar, Dr. Engledue, Dr. R. Lee, Sir J. Richardson, Dr. J. C. B. Williams, Dr. W. Carpenter, Professor Clarke, Dr. King, Dr. Latham.

THE SENSE OF TOUCH REFERABLE TO THE BLIND AND THE DEAF.—Dr. Fowler read a paper on this subject, affirming that conceptions are stronger than sensations, and adducing, among other instances, the case of the person who, having his foot amputated, though he felt days afterwards a sensation in his toe.

"The Cause of the Blood's Circulation through the Liver," a paper by Mr. Searle, was then read.

Professor Owen and Mr. Alder also read papers.

FRIDAY.

SECT. F.—Statistics.

This section sat in a small apartment of the Victoria Rooms, and was not fully attended.

POOR-LAW RELIEF.—Dr. Alison, of Edinburgh, read a report on this subject in reference to the medical relief to the parochial poor of Scotland under the former law. Dr. Alison considered that this inquiry would supply the best test of the efficiency of the voluntary system of relief which had prevailed in Scotland until the new poor-law. Returns had been obtained from 40 towns, and it was found that in 16 of them the parochial authorities had supplied no medical relief at all, and in the rest only trifling occasional payments had been made, chiefly during the prevalence of some epidemic. Twenty-five practitioners had made a return of the estimated money value of their unrequited professional labour bestowed on sick paupers; the average was £10 5s. 7d. a year. In 33 out of the 40 towns in question no alteration had yet taken place. Of 325 professional men in the country districts of Scotland who had been applied to, 305 had furnished information respecting their remuneration for attending sick paupers; 94 of them had been receiving some remuneration, 39 of them an annual one varying from a few shillings for drugs up to £20, but only 13 received above £5 a year; among those who had received no regular annual sum, two had been paid 3s. each; in one case that was the sole remuneration received during 12 years of attendance on a number of paupers averaging 70 constant, and 13 occasional; in the other instance it was given for attendance on passing paupers to other parishes, and the medical gentleman in that case had received nothing for 21 years' attendance on paupers numbering 14 constant patients. Of the 305, 211 had never received any remuneration of any

kind for their professional attendance upon the parochial poor, or for drugs; one of these had attended 400 paupers for 8 years. Another calculated his loss by this at £70 a year; 208 had had occasion to give wine, food, clothing, &c., to the sick poor, from their own limited incomes, or to beg such things from their wealthy neighbours for them; one had known the session sell the effects of his deceased pauper patient, and appropriate the proceeds without paying him. One hundred and thirty-six returns had been obtained of the estimated value of unrequited professional labour in the country districts; on an average the parties had been ten years in practice, and the sum total given by them to the poor in professional labour and outlay was £31,417, or about £253 each on an average; they calculated the average for each pauper, including drugs, at 4s. a year. Four fifths of these practitioners reported their opinion to be in favour of giving the poor the right of applying to any medical man in the district, instead of being compelled to resort to such as had been appointed for them by the parochial boards.

MINING IN BELGIUM.—This was a review, by Mr. R. Valpy, of the mines and mining industry of Belgium, founded on the report of the Belgian Minister of Public Works.

As a coal-providing country, Belgium ranks the second in Europe; the entire ratio of the coal districts to the total area of the three principal coal countries being, in—

Great Britain.	1-20th
Belgium.	1-22d
France	1-210th

the area of the coal districts in the above countries being, in—

Great Britain .	2,930,000 acres
Belgium. . .	335,060 "
France . .	630,000 "

and the annual produce was calculated to amount to, in—

Great Britain . .	31,000,000 tons
Belgium . .	4,500,000 "
France . .	3,980,000 "
Germanic Union	3,000,000 "

The number of coalpits, which in 1829 was about 422, increased in 1830 to 652, being a very considerable addition to this branch of mining and industrious occupation.

The accidents, during the last twenty years, were 1,352, or 100 per cent. The Belgian Government, however, has excited itself with praiseworthy energy to diminish the number of accidents by establishing enactments for the careful inspection of the works in the mines, directing the particular attention of the engineers to the maintenance of efficient ventilation, encouraging the means for the discovery of better prevention from the danger of firedamp explosion, and various other ways; and they also contribute largely to the local charitable institutions, for the benefit of the miners and their families.

SECT. A.—Mathematical and Physical Science.

THURSDAY.

President—Sir J. F. W. Herschel, Bart. Secretaries—Dr. Stevelly, and Messrs. Drew and Stokes.

The President read Professor Erman's report "On Gauss's Magnetic Constants." The president observed, that, from the careful consideration which the subject required, it would, of course, be impossible to enter on any discussion of the merits at present.

Professor Powell, "On the Bands formed by Partial Interception of the Prismatic Spectrum."

Mr. Richard Laming, "On the Constitution and Forces of the Molecules of Matter." The author's propositions, if founded on truth, involve an entirely new theory of the universe, different from any which has yet been suggested, and would entirely destroy the system of electricity supported by modern philosophers. It is, in fact, a new universal theory of physical causation, which regards electricity as the sole cause of gravitation, by reason of an attraction in exercise between the atoms of electricity for one another. Electricity is thus made to be a material body, and to exist, in combination with the molecules of matter, in different and definite quantities, thereby giving to them their respective weights, cohesion, and affinities. The molecule of matter is represented as composed of a central basic atom, which has no action on similar basic atoms, but attracts around it atoms of electricity and caloric. The atoms of electricity attract around them atoms of caloric, and repulsion as a force is excluded from nature altogether; and thus the whole mechanism of creation is made to depend upon an attractive force only. The theory was illustrated by diagrams; and the demonstrations proceeding upon numerical calculations and geometrical measurements of the most simple kind, embracing the greater part of the phenomena of electricity with the leading facts in chemistry. The memoir excited considerable interest; but, as the president, Sir John Herschel, remarked, its subject was of too vast a character, and the propositions too numerous, to be followed out into all their consequences during a morning meeting. The memoir is to be followed by an experiment suggested by it, in order to prove the fact that electricity is a ponderable body. Mr. Laming said, what he contended for was, that instead of their being two electricities in nature, there was only one; and that a body being negative implied that it was charged with a greater quantity of electricity than it naturally attracted, the excess being the electrical complement, or the excess of electricity over the electrical equivalent of the atom, which excess arose from the disengaged electricity uniting with the atom near it which happened to have the least diameter in its electrical equivalent. He added, that he brought forward the subject only after many years of study and experiment.

The other papers read at this section were, "On the Variation of the Magnetic Needle," by Mr. J. G. Hartley; and "On Magnetic Causation and Intrinsic Forces," by Mr. G. Fowler.

SECT. C.—Geology and Physical Geography.

President, Leonard Horner, Esq., F.R.S., Pres. of Geolog. Society.

Vice-Presidents—The Very Rev. Dr. Buckland, Dean of Westminster; Sir Henry De la Beche, F.R.S., Director-General of the Geological Survey of the United Kingdom; William Henry Fitton, M.D., F.R.S.; William Hopkins, F.R.S. (For Geography) G. B. Greenough, Esq., F.R.S.

Secretaries.—Robert A. Austen, Esq., F.R.S.; Professor Oldham, M.R.I.A.; J. H. Norton, M.D. (For Geography) Charles T. Beke, Esq., Ph. D.

Committee.—Professor Agassiz; Professor Ansted, F.R.S.; Monsieur Le Blanc; Major Shadwell Clerke, F.G.S.; Charles Darwin, Esq., F.R.S.; Mr. Duncan (the African traveller); Professor Edward Forbes, F.R.S.; G. W. Featherstonhaugh, Esq., F.G.S., Monsieur Graves; Robert Hutton, Esq., F.G.S.; W. J. Hamilton, Esq., Sec. G.S.; J. Boscawen Ibbetson, Esq., F.G.S.; W. King, Esq.; Monsieur de Koninck; Charles Lyell, Esq., F.R.S.; Professor Von Middendorf; Robert Mallett, Esq., Pres. G.S., Dublin; Marquis of Northampton, Pres. R.S.; Monsieur Puteville; W. Sanders, Esq.; William Sharpe, Esq., F.R.S.; Rev. — Walker; James Yates, Esq., F.R.S.; Lieut.-Colonel Colby, R.E., F.R.S.; G. W. Ormerod, Esq., M.A., F.G.S.; John Phillips, Esq., F.R.S.

THURSDAY.

Mr. Keele, "On the Artesian Well, Southampton," was the first paper read.

The other papers read were—

Goeppert, professor, of Breslau, communicated by Sir R. I. Murchison, "On the Origin of the Coal in the Silesian Coal Fields." The professor thinks the origin to be by deposit of vegetables on the spot where they had existed after the manner of our peat moors.

Ormerod, Esq., communicated a paper, "On the Northwich Salt Field," which was illustrated by diagrams.

W. Sharp, Esq., who had a paper "On the Salt Mines of Cheshire," withdrew it, considering that the subject had been fully treated by Mr. Ormerod. Mr. Sharp said the principal mine was well worthy of a visit. It was 112 yards deep, but was easy and safe of descent. At the bottom was a vast area, one mile in circumference, and fifteen yards high, supported by pillars of salt twelve yards square. This space, when illumininated with blue lights, formed a splendid exhibition.

Sub-section of Ethnology.

BUGLE-HALL.

President.—Admiral Sir Charles Malcolm, K.C.B., P.E.H. Soc.

Vice-Presidents.—Dr. Prichard, Dr. R. G. Latham, Dr. Hodgkin.

Secretary.—Dr. King.

Committee.—Rugendaz, W. Ogilvy, Esq., J. B. Jukes, Esq., Dr. Beke.

"On the Comanche Indians." By W. Bollaert, Esq.

"On the Indians of Texas." By W. Bollaert, Esq.

"Remarks on a Comanche Vocabulary." By Dr. G. Latham. According to the evidence of language, the Comanches were disconnected with the other tribes both of Texas and the United States. Their specific affinities were with the Shoshonie, or Snake Indians, on the boundaries of the Oregon territory, New Mexico, and California.

THURSDAY.

SECT. D.—Zoology and Botany.

VICTORIA ROOMS.

President.—Sir John Richardson, M.D., F.R.S.

Vice-Presidents.—Charles Darwin, M.A., F.R.S.; Dr. Robert Brown, F.R.S., V.P.L.S., Professor E. Forbes, F.R.S.; H. E. Strickland, Esq.

Secretaries.—Dr. Lankester, F.R.S. T. V. Woollaston, Esq., B.A., F.C.P.S.; H. Wooldridge, Esq.

Committee.—W. Spence, F.L.S.; — Priaulx, Esq.; Dr. W. Carpenter, F.R.S.; G. T. Fox, Esq., F.R.S.; John Hogg, Esq., F.L.S.; Von Middendorf; Robert Ball, Esq., M.R.I.A.; William Thompson, Esq.; Robert M'Andrew, Esq.; Professor Ansted, F.R.S.; Professor Agassiz; Hewitt Watson, Esq.; C. C. Babington, Esq., M.A., F.L.S.; George Newport, Esq., F.R.S.; Professor Owen, F.R.S.; Rev. Leonard Jenyns; W. Yarrell, Esq., F.L.S.; Professor Bell, F.R.S.; Professor Balfour; R. Patterson, Esq.; J. Gould, Esq., F.R.S.

Hogg, John, Esq., F.L.S.—"Additions to a Synopsis of the Classification of the Genera of British Birds."

A paper was read from Mr. J. Blackwall, containing a "List of Periodic Birds at Llanwst."

"An Account of some Shells and other Invertebrate Forms found on the Coast of Northumberland and of Durham. By Wm. King, Curator of the Newcastle Museum." Most of the objects treated of in this paper were obtained at different times from the cobbles and decked boats which frequent the fishing-grounds between the Dogger bank and the coast stretching from the Tweed to the Tees. The following are the principal shells and corals, &c., obtained:—Halicondria mammillaris, Halicondria nov. sp., Retepora Beaniana, Hypothyris psittacea, Pecten radiatus, Crenella decussata, Crenella nigra, Modiola vulgaris, Leda minuta, Astarte Scotica, Axinus flexuosus, Cyprina Islandica, Myris undata, Mya Truncata, Panopaeda Arctica, Rimula Noachina, Tuochus Millegranus, Scalaria Trevelyaniana, Natica Gadenlandica, Fusus Antiquus, Fusus Norvegicus, Fusus Turtoni, Fusus Islandicus, F. Berniciensis; and Buccinum Undatum. The animals were brought up

by dredging, and found in the pleistocene beds of the tertiary strata. He confirmed Captain Laskey's observations, which announced the discovery of these animals many years ago. One of the species found by the captain, the terebratula cetacea, had been found by Mr. King. The statement of the existense of such animals on our seas when made by Laskey was doubted.

Professor E. Forbes pointed out, on a map of the British isles, the localities where the bodies had been dredged. He said that the extinct species spread over the greater part of the tertiary strata, but many of them were identical with existing species. Most of these animals which now existed were found only in the northern seas, not farther south than the North Cape, though on the coast of America they extended as far south as Cape Cod. They were entirely unknown in the British seas. Some of the living specimens were also extremely curious and very rare. They were particularly interesting as serving to clear the reputation of Captain Laskey, a Scotch naturalist, who had described a number of new shells found in the Scottish seas, many of which were believed not to be natives of our seas. He was supposed to have fraudulently inserted them in his catalogue, and he was consequently alluded to in modern works of conchology as being no authority whatever. It could not be doubted, however, that some of the species which Captain Laskey mentioned were washed out of ballast heaps, and were in reality only natives of the West Indies.

Professor Owen read his paper "On the Homologies of the Vertebræ, and on the Temporal Bone." He said his object was to establish ideal type of the skeletons of vertibrated animals, by which the homology of one bone in one animal with another bone in another animal might be fixed. He employed the word "homology" as it was used by German writers in contradistinction to "analogy." The bones of the fore limb of a lizard, for instance, were homologous to those of the fore limb of a mammal, while those in the wing of a bird would be only analogous to them. He might add that the term had a directly different signification in the sense in which he used it from what it had in logic. A bone might have three different kinds of homologous relations — namely, special, general or ultimate, and serial. What was one bone in one animal might constitute five or six distinct bones in another, as single bones in the human skeleton were often compound bones in other animals; but the definition which he attached to the word "bone" might be understood when he stated that he took the temporal bone in the human skull as being one bone, and not as being composed of several bones united together. The learned professor then proceeded, by reference to a number of well-executed diagrams, to explain his theory by a comparison between the temporal bone of human anatomists with corresponding bones in the skeletons of the echidna or ovo-viviparous mammal, the ostrich, the crocodile, the amphibian, and the fish.

Professor Forbes next read a paper on the "Pulmograde Medusæ of the British Seas," with notices of the Medusæ at present abundant in the Southampton Water. The learned professor, previous to delivering his paper on the Medusæ, drew the attention of his auditors to an exhibition in a glass of a Mortella, and two small Lancelletts. Both were found on the Cornish coast; the latter was considered the most curious species in British zoology, burying itself in the sand, with its head only appearing; and if disturbed would swim about with great rapidity, and then again bury itself in the sand, as was shown by the glass case in which it was exhibited. The professor stated that the Mertella had been placed in a glass globe, with two other Lancelletts, and, although a much smaller animal, he had found means to devour both, commencing his attacks in an Abyssinian fashion—namely, in the parts not vital. He then proceeded to treat of the Medusæ, commonly known as the Jelly Fish, and no where more abundant than in the Southampton Water. He then proceeded to enumerate and describe the varieties, which he had condensed, in opposition to the opinions of previous naturalists, into three species. The professor was listened to with great attention, and received at the close of his address much applause.

MISCELLANEOUS CORRESPONDENCE.

CURRICULA OF STUDY REQUIRED BY THE COLLEGE OF SURGEONS AND THE APOTHECARIES' SOCIETY.

[To the Editor of the Medical Times.]

SIR,—Permit me, by means of your extensive circulation, to publish the following comparison of the respective qualifications required—1st. For the diploma of the College of Surgeons of London, from gentlemen who commenced their professional studies previous to 1838. 2ndly. By the Society of Apothecaries, for their license, from gentlemen who commenced their professional studies on or after the 1st of October, 1835.

COLLEGE OF SURGEONS	APOTHECARIES' SOCIETY.
Age, twenty-two years.	Age, twenty-one years.
Five years engaged in acquirements of professional knowledge.	Apprenticeship, five years.
Lectures.	*Lectures.*
Anatomy and Physiology—Two sessions.	Anatomy and Physiology—Two sessions.
Dissections—Two sessions.	Dissections Two sessions.
Surgery—Two sessions.	Principle and Practice of Medicine—Two sessions.
Physic—One session.	
Chemistry—One session.	Chemistry—One session.
Midwifery—One session.	Midwifery - Two sessions.
Materia Medica and Botany—Three months.	Materica Medica and Therapeutics — One session.
	Botany—Three months.
	Forensic Medicine—Three months.
Surgical practice of a hospital—12 months.	*Medical* practice of a hospital -18 months.
The lectures to occupy two winter, and one summer session.	These lectures to be attended in a certain order, and to occupy three winter, and two summer, sessions.

Such, Sir, are the different qualifications requisite: a single glance suffices to show which course of study affords the candidate the more useful and available knowledge in the necessities of everyday practice, as well as which embraces the more extended range of scientific acquirements. I should add, that the regulation requiring attendance on lectures on midwifery by the College of Surgeons is practically a dead letter, the candidate's knowledge of the subject never being tested by examination; and that, although the Apothecaries' Society do not require attendance on surgical lectures, the student, at his examination for the license, is expected to answer questions on that subject; such, indeed, being often more severe than the questions proposed by the College of Surgeons for their *higher grade of Fellow*. After an acquaintance with these facts, Mr. Editor, is it not extraordinary, to say the least, that in a recent attempt at medical legislation, a deliberate trial should have been made to deprive the legally-qualified apothecary of the universally-adopted title of surgeon? For the future, however, we shall possess in the Institute, a body ever on the alert to watch the attempts of such so-called medical reformers. To the care of that body I leave the subject, with all confidence in their integrity and ability.

A GENERAL PRACTITIONER.

EFFECTS OF HYDRO-SULPHURET OF AMMONIA ON THE BLOOD.

SIR,—The last number of your periodical contains an article headed, "Researches on the Human Blood" (by M. Bonnet, of Lyons), the concluding paragraph of which is as follows:—

"M. Bonnet has further remarked, that the hydro-sulphuret of ammonia destroys the globules completely, and deprives the blood of the faculty of assuming the bright scarlet colour of arterialisation." (See page 421.)

In June, 1843, you published a communication from me, in which are to be found the following inquiries:—

"Would it not, then, be of importance if any means could be suggested whereby the red globules alone might be diminished, while the other constituents of the blood remained unaffected? Could this be accomplished by the hydro-sulphuret of ammonia?" (See *Medical Times*, vol. viii., p. 201.)

I then proceeded to express my belief in the two-fold possibility that such end might be effected, and that the hydro-sulphuret of ammonia might be possessed of the power of depriving the red globules of an essential constituent—"appropriating to itself a portion of that iron which would otherwise have contributed to the formation of the red globules."

My grounds for such belief were, conjointly, the known affinity between iron and sulphur; the observed effects of hydro-sulphuret of ammonia on the economy; and the supposed function of iron in the globules?

Your very obedient servant,

HENRY FREKE.

Stevens's Hospital, Dublin, Sept. 2.

GOSSIP OF THE WEEK.

APOTHECARIES' HALL.—Gentlemen admitted members September 3:—George Todd, William Lewis Dudley, Robert Farrer.—Sept. 10: William Forster Fotherby, Edward Lowe Webb, William Edward Wright, Gordon Kenmure Hardie, George Burnside Bryden, William Hankes Day.

WAR OFFICE, September 11.—1st Regiment of Foot—Staff Surgeon of the Second Class Alexander Knox, M.D., to be Surgeon, vice Carson, who exchanges. 3rd West India Regiment—William Browne, gent., to be Assistant-Surgeon, vice Thompson, appointed to the 85th Foot.

MORTALITY TABLE.

For the Week ending Saturday, Sept. 19, 1846.

Causes of Death.	Total.	Average of 5 summers.	Average of 5 years.
ALL CAUSES	944	898	968
SPECIFIED CAUSES...	943	892	961
Zymotic (or Epidemic, Endemic, and Contagious) Diseases	200	201	188

No. **SUMMARY.** Sept. 20

STUDENTS' NUMBER.

THE RULES AND REGULATIONS OF EXAMINING MEDICAL BODIES IN ENGLAND, SCOTLAND, IRELAND, AND FRANCE.

UNIVERSITY OF LONDON.

EXAMINERS. -*Faculty of Medicine. Intellectual Philosophy, Logic, and Moral Philosophy*, Rev. Henry Alford, M.A., T. B. Burcham, Esq., M.A. *Medicine*, Arch. Billing, M.D., Alexander Tweedie, M.D., F.R.S. *Surgery*, John Bacot, Esq., Sir Stephen L. Hammick, Bart. *Anatomy and Physiology*, Francis Kiernan, Esq., F.R.S., Professor Sharpey, M.D., F.R.S. *Physiology and Comparative Anatomy*, Professor Rymer Jones, F.R.S. *Midwifery*, Edw. Rigby, M.D. *Chemistry*, W. T. Brande, Esq., F.R.S. *Botany*, Rev. Professor Henslow, M.A. *Materia Medica and Pharmacy*, Jonathan Pereira, M.D., F.R.S. *Forensic Medicine*, W. T. Brande, Esq., F.R.S., Edw. Rigby, M.D., Jonathan Pereira, M.D., F.R.S.

Examinations for the Degree of Bachelor of Medicine.—Candidates for the degree of Bachelor of Medicine shall be required, 1. To have been engaged during four years in their professional studies at one or more of the institutions or schools recognised by this university. 2. To have spent one year at least of the four in one or more of the recognised institutions or schools in the United Kingdom. 3. To pass two examinations.

The first examination shall take place once a year, and commence on the first Monday in August. No candidate shall be admitted to this examination unless he have produced certificates to the following effect:—1. Of having completed his nineteenth year. 2. Of having taken a degree in arts in this university, or in a university the degrees granted by which are recognised by the senate of this university; or of having passed the matriculation examination. 3. Of having been a student during two years at one or more of the medical institutions or schools recognised by this university, subsequently to having taken a degree in arts, or passed the matriculation examination. 4. Of having attended a course of lectures on each of four of the subjects in the following list:—Descriptive and Surgical Anatomy, General Anatomy and Physiology, Comparative Anatomy, Pathological Anatomy, Chemistry, Botany, Materia Medica and Pharmacy, General Pathology, General Therapeutics, Forensic Medicine, Hygiene, Midwifery and Diseases peculiar to Women and Infants, Surgery, Medicine. 5. Of having dissected during nine months. 6. Of having attended a course of Practical Chemistry, comprehending practical exercises in conducting the more important processes of general and pharmaceutical chemistry; in applying tests for discovering the adulteration of articles of the materia medica, and the presence and nature of poisons; and in the examination of mineral waters, animal secretions, urinary deposits, calculi, &c. 7. Of having attended to practical pharmacy during a sufficient length of time to enable him to acquire a practical knowledge in the preparation of medicines.

These certificates must be transmitted to the registrar at least fourteen days before the commencement of the examination. The fee for this examination is five pounds. No candidate can be admitted to the examination unless he have previously paid this fee to the registrar; and if he fail to pass the examination, the fee will be returned to him.

The candidates are examined in the following subjects:—Anatomy, Physiology, Chemistry, Structural and Physiological Botany, Materia Medica, and Pharmacy.

The examinations are conducted in the following order:—Morning, 10 to 1: Monday, Anatomy and and Physiology, by printed papers; Tuesday, Chemistry, by experiment and printed papers. Afternoon, 3 to 6: Monday, Anatomy and Physiology, by printed papers; Tuesday, Botany, Materia Medica, and Pharmacy, by printed papers. To commence on Friday at 10. Chemistry, Materia Medica, and Pharmacy, by *viva voce*, and demonstration from specimens. To commence on Monday, in the following week, at 10: Anatomy and Physiology, by *viva voce*, demonstration from preparations, and dissection.

On the Wednesday morning in the week following the commencement of the examination, the examiners will arrange, in two divisions, each in alphabetical order, such of the candidates as have passed: and a pass certificate, signed by the registrar, will be delivered to each candidate. Such candidates only as in the opinion of the examiners are admissible to the examination for honours, shall be placed in the first division.

Examination for Honours.—Any candidate who has been placed in the first division at the first examination, may be examined for honours in any or all of the following subjects:—Anatomy and Physiology (candidates may illustrate their answers by sketching the parts they describe), Chemistry, Materia Medica, and Pharmaceutical Chemistry.

These examinations take place in the week following the commencement of the first examination. They are conducted by means of printed papers; but the examiners are not precluded from putting *viva voce* questions upon the written answers of the candidates when they appear to require explanation. The examinations for honours are conducted in the following order:—Morning 10 to 1: Thursday, Anatomy and Physiology; Friday, Chemistry. Afternoon, 3 to 6: Thursday, Anatomy and Physiology; Friday, Materia Medica and Pharmaceutical Chemistry.

If in the opinion of the examiners sufficient merit be evinced, the candidate who shall distinguish himself the most in Anatomy and Physiology, the candidate who shall distinguish himself the most in Chemistry, and the candidate who shall distinguish himself the most in Materia Medica and Pharmaceutical Chemistry, shall each receive an exhibition of thirty pounds per annum for the next two years. Under the same circumstances, the first and second candidates in each subject shall each receive a gold medal of the value of five pounds.

Second Examination.—The second examination takes place once a year, and commences on the first Monday in November. No candidate can be admitted to this examination within two academical years of the time of his passing the first examination, nor unless he have produced certificates to the following effect:—1. Of having passed the first examination. 2. Of having, subsequently to having passed the first examination, attended a course of lectures on each of two of the subjects comprehended in the foregoing list, and for which the candidate had not presented certificates at the first examination. 3. Of having, subsequently to having passed the first examination, dissected during six months. 4. Of having conducted at least six labours. (Certificates on this subject will be received from any legally-qualified practitioner in medicine.) 5. Of having attended the surgical practice of a recognised hospital or hospitals during twelve months, and lectures on clinical surgery. 6. Of having attended the medical practice of a recognised hospital or hospitals during other twelve months, and lectures on clinical medicine. 7. Of having, subsequently to the completion of his attendance on surgical and medical hospital practice, attended to practical medicine in a recognised hospital, infirmary, or dispensary, during six months. (Certificates on this subject will be received from any legally-qualified practitioner having the care of the poor of a parish.) The candidate must also produce a certificate of moral character from a teacher in the last school or institution at which he has studied, as far as the teacher's opportunity of knowledge has extended.

The certificates must be transmitted to the registrar at least fourteen days before the examination begins. The fee for this examination is five pounds.

Candidates are examined in the following subjects:—Physiology (the papers in Physiology including questions in Comparative Anatomy), General Pathology, General Therapeutics, Hygiene, Surgery, Medicine, Midwifery, Forensic Medicine. The examination is conducted in the following order:—First Week. By printed papers. Morning, 10 to 1: Monday, Physiology; Tuesday, Surgery; Wednesday, Midwifery. Afternoon, 3 to 6: Monday, General Pathology, General Therapeutics, and Hygiene; Tuesday, Medicine; Wednesday, Forensic Medicine.—Second Week. By *viva voce* interrogation. To commence on Monday morning at 10.

On the Monday morning in the following week, the examiners will arrange, in two divisions, each in alphabetical order, such of the candidates as have passed; and a certificate under the seal of the university, and signed by the chancellor, will be delivered to each candidate. Such candidates only as in the opinion of the examiners are admissible to the examination for honours, will be placed in the first division.

Examination for Honours.—Any candidate who has been placed in the first division at the second examination, and has produced a certificate showing that he has not completed his twenty-fifth year, may be examined for honours in any or all of the following subjects:—Physiology and Comparative Anatomy (candidates may illustrate their answers by sketching the parts they describe), Surgery, Medicine, Midwifery, Structural and Physiological Botany.

The examination for honours will take place in the week following the second examination. It will be conducted by means of printed papers; but the examiners are not precluded from putting *viva voce* questions upon the written answers of the candidates when they appear to require explanation. The examination is conducted in the following order:—Morning, 10 to 1: Tuesday, Physiology and Comparative Anatomy; Wednesday, Surgery; Thursday, Medicine; Friday, Midwifery. Afternoon, 3 to 6: Tuesday, Physiology and Comparative Anatomy; Wednesday, Surgery; Thursday, Medicine; Friday, Structural and Physiological Botany.

If in the opinion of the examiners sufficient merit be evinced, the candidate who shall distinguish himself the most in Physiology and Comparative Anatomy, the candidate who shall distinguish himself the most in Surgery, and the candidate who shall distinguish himself the most in Medicine, shall each receive an exhibition of fifty pounds per annum for the next two years, with the style of University Medical Scholar. Under the same circumstances, the first and second candidates in each of the preceding subjects shall each receive a gold medal of the value of five pounds. Under the same circumstances, the candidate who shall distinguish himself the most in Midwifery, and the candidate who shall distinguish himself the most in Structural and Physiological Botany, shall each receive a gold medal of the value of five pounds.

Examination for the Degree of Doctor of Medicine.—The examination for the Degree of Doctor of Medicine takes place once a year, and commences on the fourth Monday in November. No candidate can be admitted to this examination unless he have produced certificates to the following effect:—1. Of having taken the degree of Bachelor of Medicine in this university, or a degree in medicine or in surgery at a university, the degrees granted by which are recognised by the senate of this

university. Those candidates who have not taken the degree in this university shall produce a certificate of having completed their twenty-third year. 2. Of having attended, subsequently to having taken one of the above degrees in medicine, (*a*) to clinical or practical medicine during two years in a hospital or medical institution recognised by this university; (*b*) or, to clinical or practical medicine during one year in a hospital or medical institution recognised by this university, and of having been engaged during three years in the practice of his profession; (*c*) or, if he have taken the degree of Bachelor of Medicine in this university, of having been engaged during five years in the practice of his profession. (One year of attendance on clinical or practical medicine, or two years of practice, will be dispensed with in the case of those candidates who, at the second examination, have been placed in the first division.) 3. A moral character, signed by two persons of respectability.

These certificates must be transmitted to the registrar at least fourteen days before the examination begins. The fee for the degree of Bachelor of Medicine is ten pounds.

Candidates are examined in the following subjects:—Elements of Intellectual Philosophy, Logic, and Moral Philosophy; Medicine. The examinations are conducted in the following order:—By printed papers. Morning, 10 to 1. *Monday*, Elements of Intellectual Philosophy, Logic, and Moral Philosophy. (Candidates who have taken a degree in arts in this university, or in a university, the degrees granted by which are recognised by the senate of this university, are exempted from this part of the examination. The degrees in arts of all universities in the United Kingdom are recognised by the senate for this purpose.) *Tuesday*, Medicine. Afternoon, 3 to 6. *Monday*: A Commentary on a Case in Medicine, Surgery, or Midwifery, at the option of the candidate. *Tuesday*, Medicine. —By *viva voce* interrogation. *Friday* Morning, at 10. Examination on the answers to the Printed Papers, and on the Commentaries; and the examination for a certificate of Special Proficiency in Medicine, Surgery, or Midwifery, as determined by the candidate's choice of the case for commentary.

On the Monday morning in the following week, the examiners will arrange in two divisions, each in alphabetical order, such of the candidates as have passed; and a certificate under the seal of the university, and signed by the chancellor, will be delivered to each candidate. Such candidates only as, in the opinion of the examiners, are admissible to the examination for honours, will be placed in the first division. If, in the opinion of the examiners, sufficient merit be evinced, the author of the best Commentary on the Case in Medicine, the author of the best Commentary on the Case in Surgery, and the author of the best Commentary on the Case in Midwifery, will each receive a gold medal of the value of five pounds. Any candidate may present a thesis on a subject of his own choice. If in the opinion of the examiners, sufficient merit be evinced, a gold medal, of the value of ten pounds, will be given to the author of the best thesis. The examiners are not precluded from examining the author on the subject of his thesis.

Examination for Honours.—Any candidate who has been placed in the first division may be examined for honours in any or all of the following subjects:—Surgery, Medicine, Midwifery. The examinations take place in the week following. They are conducted by means of printed papers; but the examiners are not precluded from putting *viva voce* questions upon the written answers of the candidates when they appear to require explanation.

The examinations for honours are conducted in the following order:—Morning, 10 to 1: Tuesday, Surgery; Wednesday, Medicine; Thursday, Midwifery. Afternoon, 3 to 6: Tuesday, Surgery; Wednesday, Medicine; Thursday, Midwifery.

If, in the opinion of the examiners, sufficient merit be evinced, the first candidate in each subject will each receive a gold medal of the value of five pounds.

Institutions and Schools.—No medical institution or school is recognised by the senate of this university which does not possess ample means of illustrating the instruction given at it. *Forms of Certificates*: The teacher must certify for—*Lectures*,—That in the year 18 , the pupil attended . . . his course of instruction on which commenced on . . . . and terminated at . . . . . and which consisted of . . . . . lectures and . . . . examinations. *Practical Anatomy*,—That from . . . to . . . the pupil dissected . . . . . under his superintendence. *Practical Chemistry*,—That the pupil operated . . . . during his course of Practical Chemistry, which consisted of . . . . lessons. *Practical Pharmacy*,—That the pupil prepared . . . . . medicines under his superintendence from . . to . . . . *Clinical Instruction in Surgery*,—That the pupil attended . . . . . the surgical practice of this hospital, and the course of lectures on Clinical Surgery, consisting of . . . lectures, from . . . . to . . . . *Clinical Instruction in Medicine*,—That the pupil attended . . . . the medical practice of this hospital, and the course of lectures on Clinical Medicine, consisting of . . . . lectures from . . . . to . . . *Practical Medicine*,—That the pupil attended . . . . to Practical Medicine at . . . . and was intrusted with the treatment of patients under . . . . . superintendence, from . . . . to . . . (Certificates on this subject will be received from any legally-qualified practitioner, having the care of the poor of a parish.) *Practical Midwifery*,—That the pupil conducted . . . . labours under his superintendence. Any legally-qualified practitioner shall be competent to give this certificate.

Regulations relating to Students who commenced their Medical Studies in or before January, 1840.

Degree of Bachelor of Medicine.—Candidates who commenced their professional studies in or before Jan., 1840, are admitted to the first examination for the degree of Bachelor of Medicine on producing certificates to the following effect:—1. Of having been engaged during two years in their professional studies. 2. Of having attended a course of lectures on each of four of the subjects comprehended in the former list. 3. Of having dissected during nine months. 4. Of having attended to practical pharmacy during a sufficient length of time to enable them to acquire a practical knowledge in the preparation of medicines.

Candidates who commenced their professional studies in or before January, 1840, are admitted to the second examination for the degree of Bachelor of Medicine on producing certificates to the following effect:—1. Of having been engaged during four years in their professional studies. 2. Of having passed the First Examination. 3. Of having attended a course of lectures on each of two of the subjects comprehended in the former list. 4. Of having dissected during twelve months. 5. Of having attended to practical pharmacy during a sufficient length of time to enable the pupil to acquire a practical knowledge in the preparation of medicines. 6. Of having conducted at least six labours. 7. Of having attended the surgical practice of a recognised hospital or hospitals during twelve months. 8. Of having attended the medical practice of a recognised hospital or hospitals during other twelve months. 9. Of having completed the twenty-second year of their age. 10. Of moral character, from a teacher in the last school or institution at which they have studied, as far as the teacher's opportunity of knowledge has extended.

Candidates who have not taken a Degree in Arts, or passed the Matriculation Examination in this university, will be required to translate a portion of CELSUS *de Re Medicâ*.

Regulations relating to the Practitioners in Medicine or Surgery desirous of obtaining Degrees in Medicine.

Degree of Bachelor of Medicine.—Candidates are admitted to the two examination for the degree of Bachelor of Medicine on producing certificates to the following effect:—1. Of having been admitted, prior to the year 1840, members of one of the legally-constituted bodies in the United Kingdom for licensing practitioners in medicine or surgery, or of having served, previously to 1840, as surgeons, or assistant-surgeons, in her Majesty's Army, Ordnance, or Navy, or in the service of the Honourable the East India Company. 2. Of having received a part of their education at a recognised institution or school, as required by the charter of the university. 4. Of moral character, signed by two persons of respectability.

Candidates who have not taken a Degree in Arts, or passed the Matriculation Examination in this university, will be required to translate a portion of CELSUS *de Re Medicâ*.

Degree of Doctor of Medicine.—Candidates who have been engaged during five years in the practice of their profession, may be admitted to the examination for this degree on producing certificates to the following effect:—1. Of having been engaged during five years in the practice of their profession. 2. Of having taken the degree of Bachelor of Medicine in this university.

Candidates who have not taken a Degree in Arts or passed the Matriculation Examination in this university, will be required to translate a portion of CELSUS *de Re Medicâ*.

The regulations respecting the transmission of the certificates to the registrar, the fees, the periods, and the mode of conducting the examinations, and the arrangement of the candidates after examination, are the same for all candidates for the same degrees.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

According to the regulations of this College, no one will be admitted as a candidate for the license, unless he shall have attained the age of six-and-twenty, and shall present a certificate of good moral conduct. His medical education must comprise Anatomy, the Theory and Practice of Medicine, Forensic Medicine, Chemistry, Materia Medica, Natural History, principally Botany, Midwifery, and the principles of Surgery, and must extend over the period of five years. Practical Medicine must be studied for three years in a hospital containing at least 100 beds, and having a complete staff of physicians and surgeons. Those who have studied abroad, in addition to giving proof of five years' medical education according to the usual course of study, are required to present testimonials of a twelvemonth's medical practice at any hospital in Great Britain, having the qualifications as above.

No one will be admitted as a Licentiate (*Permissus*) who is accustomed to use any secret medicine or nostrum in the treatment of disease, unless, previously to his first examination, he make known to the president and censors its composition and the manner in which it is employed. Every Candidate must undergo three examinations, each conducted at different times, before the president and censors in *comitia minora*. The first examination comprises Physiology, the second Pathology, and the third Therapeutics. After the first examination, the president may inquire of the candidate where he studied polite literature and the principles of science, and what honours he has obtained, whether in Philosophy, Arts, or Medicine, in order that the answers may be recorded by the registrar. The candidate will also be examined in Greek works on medicine, to wit, Hippocrates, Galen, or Aretæus. Passages from the aphorisms of Hippocrates or Galen will be brought forward during the first examination; and during the second and third, passages from Hippocrates, Galen, or Aretæus, which must be translated into Latin, and illustrated with a brief commentary. If the candidate be deficient in his knowledge of Greek, he will be required to translate parts of Celsus or Sydenham, or some other Latin work on Medicine, into English. The examinations are conducted in Latin or English at the pleasure of the censors.

Whenever a candidate has passed the prescribed examinations, and has been approved, he will be proposed at the next *comitium majus* (a meeting of the Fellows at large) to be admitted as a licentiate; and, if the majority present consent, he will be admitted accordingly. If, however, the candidate be rejected, he cannot present himself for re-examination for a twelvemonth.

Before the licentiate is admitted, he is required to plight his faith to the College according to a formula, pronounced by the President before the Fellows assembled in *comitium majus*.

If any one holding the license of the College practise Pharmacy afterwards, or engage in merchandise, he is liable to expulsion; and any person practising medicine in London, or within seven miles thereof, without having previously obtained the collegiate license, is to be admonished by letter to cease his practice, until after he has passed the required examinations; and, if he continues to practise, despite this admonition, then *legibus regni obnoxius erit.*

Persons who have attained their fortieth year, seeking to become Licentiates of the College, but whose medical education is not altogether in accordance with the regulations already stated, must present testimonials of professional knowledge and good moral conduct, and if these are satisfactory, they will be admitted to examination, the same as for licentiates in general.

The old regulation restricting the fellowship, as a matter of right, to the graduates of Oxford, Cambridge, and Trinity College, was repealed in the latter part of 1835; and after Easter, 1836, all candidates were declared to be admissible as licentiates only, from which class, when duly qualified, a certain number are to be annually elected fellows in *comitia majora.* The advantages derived by graduates of the English universities, and by the Irish graduate who possesses an *ad eundem* degree from an English university, is, that they are eligible a year after they have obtained the licence; the Scotch graduate, being M.A. or B.A., five years later. If the latter does not possess any degree in arts, his eligibility for the fellowship does not occur until after the lapse of seven years. The Irish graduates who do not possess an *ad eundem* degree are not eligible for two years after they are licensed. The president and censors propose the candidates for the fellowship, but the *comitia majora* may reject the proposition, and choose their nominees. The election is by ballot.

The president of the college is *ex-officio* president of the Vaccine Board, a trustee of the British and Hunterian Museum, physician to the Queen, and an elector to the Tancred scholarships. The college has the power of recommending a physician to Christ Church, St. Thomas's, and St. Bartholomew's Hospitals; but if the recommendation succeed, it is then required to pay an annual stipend of £30 or £40 to the physician. The college also appoints the professor of botany to the University of Oxford.

The examinations for the license are conducted by the president and censors. The periods at which they take place are Michaelmas, Christmas, Easter, and in the month of June. The new censors are elected on the 24th of June, when the Harveian oration is delivered. The lectures are delivered in the early part of the year. There are about fifteen delivered; three Gulstonian, three Croonian, and three Lumleian, so called from the names of those who left endowments to the college for the purpose, and six lectures on Materia Medica. The museum and library are attached to the institution, to which the fellows, and, by permission, their friends, have access.

The president may each year propose one candidate for the license, he being an M.D., but not otherwise eligible; and he may also name annually a licentiate of ten years' standing for the fellowship. The fellows have also the power of proposing a licentiate of seven years' standing, who is thirty-six years of age, for the fellowship; but this has been done so rarely as to be, in fact, obsolete.

The college fees are £56 17s. for the license; the fellow pays in addition, £1 1s. annually to the collegiate fund.

If any fellow or licentiate can be proved, to the satisfaction of the president and censors, to have wilfully accused any other fellow or licentiate of professional ignorance, &c., unless it be before the legally-constituted judges, he shall be fined £4 for the first offence, and £8 for the second; if he offend a third time, if a fellow, he shall be expelled, and if a licentiate fined £10. This last fine is to be enforced every time afterwards the licentiate shall so offend. If any fellow or licentiate shall offer his professional assistance to any patient whom he shall know to be under the care of another physician, whether fellow or licentiate, without having been called in to see the patient professionally, he shall be fined 40s.

If any fellow be proved to have made any arrangement with a druggist, to share with him the proceeds in his prescriptions, he shall be expelled; if a licentiate have entered into a similar arrangement, he shall be fined £10 every time he shall so offend.

Every physician, whether fellow or licentiate, shall attach to each prescription which he writes the day of the month, the name of the sick man, and his own initials. When a consultation takes place, it is to be carried on with modesty, not in the presence of the sick; and if any difference of opinion occurs, it is to be stated with prudence and moderation, so that it may not be noticed by the patient or the friends, but, if requisite, should be mentioned by the ordinary medical attendant. Whoever infringes these regulations will be fined £5 by the president and censors.

No fellow or licentiate may consult, in London, or within seven miles thereof, with a physician who does not belong to the college, under a penalty of £5 fine.

All fines are to be paid immediately.

The president and court of the college have the power of committing individuals condemning their authority to Newgate. This power has been exercised by the court, but not of late years.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

New Regulations for Candidates for the Fellowship of the Royal College of Surgeons of England.

1. That every candidate for the fellowship, whether a member of the college or not, shall produce certificates satisfactory to the court of examiners,—

That he is twenty-five years of age.

That he is (if found qualified upon his examination) a fit and proper person to be admitted to the fellowship, and the certificate of which shall be signed by three fellows.

That he has attained a competent knowledge of the Greek, Latin, and French languages, and of the elements of mathematics.

That he has been engaged for six years in the acquirement of professional knowledge in recognised hospitals or schools of surgery and medicine within the United Kingdom of Great Britain and Ireland, or in foreign countries, and that three of such years at least have been passed in one or more of such recognised hospitals or schools in London.

That he has attended the surgical practice of a recognized hospital or hospitals during four years, and the medical practice of a recognised hospital or hospitals for one year.

That he has studied anatomy and physiology by attendance on lectures and demonstrations, and by dissections, during three winter sessions of not less than six months each, at one or more recognised school or schools.

That he has attended lectures on the theory and practice of medicine, and on clinical medicine, and also on the theory and practice of surgery, and on clinical surgery, during two sessions of six months each, at one or more recognised school or schools.

That he has attended one course of lectures on each of the following subjects, viz.: chemistry, materia medica, midwifery, medical jurisprudence, and comparative anatomy, at one or more recognised school or schools. And that he has served the office of house-surgeon or dresser in a recognised hospital in the United Kingdom. Every such candidate (except in the case and instances hereinafter provided for to the contrary) shall also present for examination clinical reports, with observations of six or more surgical cases taken by himself at a recognised hospital or recognised hospitals within the United Kingdom, with sufficient certificates of their authenticity and genuineness, and shall leave such reports at the college.

3. That as to any candidate, who shall have taken the degree of bachelor of arts in an English university, and shall produce satisfactory evidence thereof, it shall, instead of the certificate or certificates that he has been engaged for six years in the acquirement of the professional knowledge as before mentioned, be sufficient for him to produce a satisfactory certificate or certificates that he has been engaged for five years in the acquirement of professional knowledge in recognised hospitals and schools of surgery and medicine within the United Kingdom, or in foreign countries, and that three of such years at least have been passed in one or more of the recognised hospitals or schools of London; and that it shall not be necessary for any candidate having so taken the degree of bachelor of arts to produce any certificate of his having acquired a competent knowledge of the Greek, Latin, and French languages, and of the elements of mathematics.

4. That upon the 1st day of January, 1850, or at any earlier period which may be thought proper, the council shall, under such regulations, and for such time or period as to them shall seem proper (but always subject to removal at the pleasure of the council), appoint three persons, and being, or not being, and either all, or in part, members of the college, as the council shall think proper for the purpose of examining persons intending to become candidates for the fellowship, and required to be examined in the Greek, Latin, and French languages, and in the elements of mathematics; and the said council, from time to time after the first appointment of such persons for such purpose as aforesaid, and as often as shall be necessary, or to the said council shall seem proper in their behalf, shall appoint such other person and persons as to them shall seem fit and proper to succeed or supply the place or places of any person or persons previously appointed for such purpose; and that, from and after the first appointment of any such persons for the purpose of making such examination as aforesaid, no certificate of a candidate having competent knowledge of the Greek, Latin, and French languages, and of the elements of mathematics, shall be received or allowed by the court of examiners, except the certificate or certificates of the persons for the time being so appointed as aforesaid.

5. That all members of the college, future as well as present, shall be entitled to be admitted to the examination for the fellowship according to the foregoing by-laws and ordinances.

6. That any person who shall have been a member of the college on the 14th day of September, 1844, shall, after the expiration of eight years from the date of his diploma, also be entitled to be admitted to the examination for the fellowship upon the production of a certificate signed by three fellows that he has been eight years in the practice of the profession of surgery, and that he is a fit and proper person to be admitted a fellow, if upon examination he shall be found qualified.

7. That any person who shall have become a member of the college after the said 14th day of September, 1841, shall, after the expiration of twelve years from the date of the diploma, also be entitled to be admitted to the examination for the fellowship upon the production of a certificate signed by three fellows that he has been for twelve years in the practice of the profession of surgery, and that he is a fit and proper person to be admitted a fellow, if upon examination he shall be found qualified, and also if he have not taken the degree of Bachelor of Arts in an English university, of a certificate or certificates that he has a competent knowledge of the Greek, Latin, and French languages, and of the elements of mathematics.

EXAMINATION OF CANDIDATES FOR THE FELLOWSHIP.

1. The examination for the fellowship shall be held three times in the year, at or within such periods as the council shall from time to time determine.

2. Each candidate shall be examined on two days, either successive or at such an interval as the Court of Examiners may appoint.

3. The subjects for the first day's examination shall be anatomy and physiology; those of the second pathology, therapeutics, and surgery.

4. The time allowed for examination each day shall be from ten o'clock in the forenoon until five o'clock in the afternoon.

5. The examination shall be conducted in the following manner. Each candidate shall, upon going in for examination, have delivered to him a written or printed copy of such questions as shall have been previously determined upon by the Court of Examiners, and to which questions he shall give written answers, and which answers shall be considered by the Court of Examiners.

The court may, however, if they should think fit, interrogate any candidate on any matters connected with the questions or answers. In the anatomical examination, the candidate shall also perform dissections and operations on the dead body in the presence of the Court of Examiners, or of such members thereof as may be deputed by the court to superintend the same. Candidates whose qualification shall be found insufficient shall not be allowed to present themselves a second time until after the expiration of one year from their first examination.

The Court of Examiners shall report in writing to the council the names of such persons as they shall have found upon examination to be qualified for the fellowship.

‚ Members of the college will pay ten guineas besides charges for status, and non-members thirty guineas.

Regulations of the Council respecting the Professional Education of Candidates for the Diploma who commenced their Studies before the year 1838.

1. Candidates will be required to bring proof—1. Of being twenty-two years of age. 2. Of having been engaged five years in the acquirement of professional knowledge. 3. Of having studied anatomy and physiology, by attendance on lectures and demonstrations, and by dissections, during two anatomical seasons. 4. Of having attended at least two courses of lectures on surgery, delivered in two distinct periods or seasons; each course to comprise not less than sixty lectures. 5. Of having attended lectures on the practice of physic, on chemistry, and on midwifery, during six months, comprising not less than sixty lectures respectively, and on botany and materia medica, during three months. 6. Of having attended during twelve months the surgical practice of a recognised hospital in London, Dublin, Edinburgh, Glasgow, or Aberdeen; or, for six months, in any one of such hospitals, and twelve months in any recognised provincial hospital.

Regulations of the Council respecting the Professional Education of Candidates for the Diploma after the Termination of the Session 1839-1840.

1. Candidates will be required to bring proof—1. Of being not less than twenty-one years of age. 2. Of having been engaged in the acquirement of professional knowledge for not less than four years, three of which shall have been passed in a recognised school or schools of surgery; three months of vacation being allowed in each year, and in the event of absence or absences from such school or schools during the said term of three years (exclusive of the vacations), the full term being completed in a subsequent year. 3. Of having studied anatomy and physiology, by attendance on lectures and demonstrations, and by dissections, during two anatomical seasons. 4. Of having attended at least two courses of lectures on surgery, delivered in two distinct periods or winter seasons of six months, each course to comprise not less than seventy lectures. 5. Of having attended one course of lectures on the practice of physic, and one on chemistry, during six winter months, comprising not less than seventy lectures respectively; one course on materia medica with medical botany during six months, and one on midwifery during six months, each comprising not less than sixty lectures; and at least twenty-five lectures on medical jurisprudence. Certificates of attendance on these lectures during the summer season will be received, provided they are equally divided over a period of four months. The lectures on medical jurisprudence may be delivered three days in the week. 6. Of having attended, during twenty-one months, the surgical practice of a recognised hospital in London, Dublin, Edinburgh, Glasgow, or Aberdeen; or for twelve months in any one of such hospitals, and twelve months in any recognised provincial hospital. 7. Of having attended the medical practice of a hospital or dispensary during six months.

II. Members and licentiates in surgery of any legally constituted college of surgeons in the United Kingdom, and graduates in surgery of any university, requiring residence to obtain degrees, will be admitted for examination on producing their diploma, licence, or degree, together with proofs of being twenty-two years of age, and of having been occupied five years in the acquirement of professional knowledge.

N.B. Certificates will not be recognised from any hospital unless the surgeons thereto, or a majority of them, be members of one of the legally constituted colleges of surgeons in the United Kingdom; nor from any school of anatomy, physiology, or midwifery, unless the respective teachers be members of some legally constituted college of physicians or surgeons in the United Kingdom; nor from any school of surgery, unless the respective teachers be members of some legally constituted college of surgeons in the United Kingdom. Certificates will not be received on more than two branches of science, from one and the same lecturer; but anatomy and physiology—demonstrations and dissections—materia medica and botany—will be respectively considered as one branch of science.

Regulations of the Council respecting the Professional Education of Candidates for the Diploma. August 15, 1843.

1. Candidates will be required, in addition to a certificate of being not less than twenty-one years of age, to bring proof—1. Of having been engaged in the acquirement of professional knowledge for not less than four years; during which period they must have studied practical pharmacy for six months, and have attended one year on the practice of physic, and three years on the practice of surgery, at a recognised hospital or hospitals in the United Kingdom; —three months being allowed for a vacation in each year. (By a resolution of the council, on the 7th of November, 1839, no provincial hospital will, in future, be recognised by this college which contains fewer than 100 patients, and no metropolitan hospital which contains fewer than 150 patients.) 2. Of having studied anatomy and physiology, by attendance on lectures and demonstrations, and by dissections, during three winter sessions, of not less than six months each. 3. Of having attended at least two courses of lectures on the principles and practice of surgery, delivered in two distinct periods or seasons; and one course on each of the following subjects—viz., the practice of physic, chemistry, and materia medica, and midwifery with practical instruction.

Certificates will not be received unless the candidate have duly registered his tickets. The other regulations are virtually the same as before.

These three forms of regulations are in force respecting candidates for the diploma, according to the period when they commenced their studies.

Fee for the diploma (including stamp), £22; for an articled student (allowed in the diploma fee), £10 10s.; for a certificate of having had the diploma, £5 5s.; for being enfranchised, £10 10s.; a certificate for a surgeon in the Royal Navy, or East India Company's service (allowed in diploma fee), £5 5s.; for an assistant surgeon, £2 2s.; for a candidate calling a special court, £5 5s.

Studentships in Anatomy.—Three studentships in human and comparative anatomy have been instituted by the college, to be held by each student for the term of three years, at a salary of one hundred pounds per annum. And with the view of promoting the objects of the college, in the institution of these studentships, the commander-in-chief of the army, the lords commissioners of the admiralty, and the court of directors of the East India Company, have placed at the disposal of the president and the council an assistant surgeoncy in each service, once in three years, for such of the said students as may be considered worthy of these honourable distinctions. 2. Candidates to be members of the college, under twenty-six years of age. 3. The council will determine annually whether one or more of such appointments shall take place during the current year, and will notify its resolution by public advertisement. 4. The appointment is made in the month of June, or as soon after as possible. 5. The students are subject to such duties and restrictions as the council shall from time to time direct; and in case of misconduct are liable to dismissal. 6. Candidates are required to transmit to the secretary, on or before the 1st of May, their applications for the appointment, together with certificates of general good character, and of fair acquirements in general learning, signed by two qualified members of the medical profession. 7. A meeting of the museum committee will be held as soon after the 1st of May as conveniently may be, at which the applications of the persons offering themselves will be examined, and, if approved, the applicants will be admitted as candidates. 8. The museum committee will determine the merits of the several candidates, and report to the council which, in their opinion, possess the highest merit. 9. The students are required to attend in the museum daily (Sundays excepted), from ten till four o'clock, and are under the immediate direction of the museum committee.

JACKSONIAN prizes of twenty guineas. The prize for the year 1845 is Tumours of the Uterus and its Appendages, their Structure, Pathology, and Treatment.

Candidates to be members of the college, not of the council.

The dissertations to be in English; and the number and importance of *original facts* will be considered principal points of excellence. Recited cases to be placed in an appendix.

Each dissertation to be distinguished by a motto or device; and accompanied by a sealed paper, containing the name and address of the author, and having, on the outside, a motto or device corresponding with that on the dissertation.

The dissertations to be addressed to the secretary, and delivered at the college before Christmas-day, 1845.

The manuscript prize dissertations, and every accompanying drawing and preparation, will become the property of the college.

Those dissertations which shall not be approved, with their accompanying drawings and preparations and correspondent sealed papers, will be returned upon authenticated application within the period of three years; and those manuscripts which shall remain three years unclaimed, and every accompanying drawing and preparation, will become the property of the college; at which period their accompanying papers, containing the names of the respective authors, will be burned, unopened.

The subject of the COLLEGIAL Triennial Prize of Fifty Guineas is, the Anatomy of the Fibres of the Cerebrum, Cerebellum, and Spinal Cord in the Human Subject; together with the origin of the Cerebral, Spinal, and Sympathetic Nerves; specially illustrated by the Anatomy of the same Parts in the lower Vertebrate Animals.

Candidates to be members of the college, not of the council.

The dissertations to be in English, and to be distinguished by a motto or device, accompanied by a sealed paper, containing the name and residence of the author, and having on the outside a motto or device corresponding with that on the dissertation.

The dissertations to be addressed to the secretary, and delivered at the college before Christmas-day, 1845.

The manuscript prize essay, with every accompanying drawing and preparation, will become the property of the college; the other dissertations and their corresponding sealed papers will be returned, upon authenticated application within the period of three years; after which period, the papers containing the names of the respective authors will be burned, unopened, and the manuscripts will become the property of the college.

The *museum* is opened to visitors on Monday, Tuesday, Wednesday, and Thursday, from 12 till 4, except during the month of September; on Friday to gentlemen for studying in it; and on Saturday,

from 10 till 1, to gentlemen desirous of comparing specimens with those in the museum. The *library* is open to members and students of the college, and visitors having tickets of admission, daily (Sundays excepted), from the 1st of October to the 1st of April, from 10 till 4; and from the 1st of April to the 1st of September, from 10 till half-past 5.

The lectures at the college by the professors are delivered in the spring of the year, the Hunterian oration on the 14th of February.

APOTHECARIES' HALL.

Every candidate for a certificate of qualification to practise as an apothecary will be required to produce tessimonials:—1. Of having served an apprenticeship of not less than five years to an apothecary. 2. Of having attained the full age of twenty-one years. 3. Of good moral conduct. 4. And of having pursued a course of medical study, in conformity with the regulations of the court.

Course of Study.

Every candidate whose attendance on lectures commenced on or after the 1st of October, 1835, must have attended the following lectures and medical practice during not less than three winter and two summer sessions: each winter session to consist of not less than six months, and to commence not sooner than the 1st nor later than the 15th October; and each summer session to extend from the 1st of May to the 31st of July.

First Winter Session.—Chemistry; Anatomy and Physiology; Anatomical Demonstrations; Materia Medica and Therapeutics: this course may be divided into two parts of fifty Lectures, each one of which may be attended in the Summer.

First Summer Session.—Botany and Vegetable Physiology; either before or after the first Winter Session.

Second Winter Session.—Anatomy and Physiology; Anatomical Demonstrations; Dissections; Principles and Practice of Medicine.

Second Summer Session.—Forensic Medicine.

Third Winter Session.—Dissections; Principles and Practice of Medicine.

Midwifery, and the Diseases of Women and Children, two courses in separate sessions, and subsequent to the termination of the first Winter Session. Practical Midwifery, at any time after the conclusion of the first course of Midwifery Lectures.

Medical Practice during the full term of eighteen months, from or after the commencement of the second Winter Session; twelve months at a recognised hospital, and six months at a recognised hospital, or a recognised dispensary; in connection with the hospital attendance, a course of Clinical Lectures and instruction in Morbid Anatomy will be required.

The sessional course of instruction in each subject of study is to consist of not less than the following number of lectures:—One hundred on Chemistry—One hundred on Materia Medica and Therapeutics—One hundred on the Principles and Practice of Medicine—Sixty on Midwifery and the Diseases of Women and Children—Fifty on Botany and Vegetable Physiology.

Every examination of an hour's duration will be deemed equivalent to a lecture. The lectures required in each course must be given on separate days. The lectures on Anatomy and Physiology, and the Anatomical Demonstrations, must be in conformity with the regulations of the Royal College of Surgeons of London in every respect. Students must also produce testimonials of attendance on a course of Clinical Lectures; of instruction in Practical Chemistry and Morbid Anatomy; and of having dissected the whole of the human body once at least; without which testimonials the candidate cannot be admitted to examination.

The above course of study may be extended over a longer period than three winter and two summer sessions, provided the lectures and medical practice are attended in the prescribed order and in the required sessions.

Those gentlemen whose attendance on lectures commenced before the 1st of October, 1835, will be allowed to complete their studies in conformity with the previous regulations of the court.

No member of the court of examiners will be recognised as a lecturer on any branch of Medical Science. The court will not recognise any lecturer unless he lectures in connection with a recognised medical school; nor will they recognise a lecturer on more than *two* branches of medical science; nor until he has produced very satisfactory testimonials of his attainments in the science he purposes to teach, and of his ability as a teacher thereof, from at least two persons of acknowledged talents and distinguished acquirements in the particular branch of science in question; and also given a public course of lectures on the subject he purposes to teach; but if, after such preliminary course, the lecturer shall be recognised, certificates of attendance on that course will be received.

Satisfactory assurance must also be given that the teacher is in possession of the means requisite for the full illustration of his lectures, viz, that he has, if lecturing—On Chemistry, a laboratory and competent apparatus—On Materia Medica, a museum sufficiently extensive—On Botany, a hortus siccus, plates or drawings, and recent plants—On Midwifery, a museum, and such appointments in a public institution as may afford the means of practical instruction to the pupils.

No hospital will be recognised by the court unless: 1. It contain at least one hundred beds. 2. It be under the care of two or more physicians, members of the Royal College of Physicians of London, or graduated doctors of medicine of a British university. 3. The physicians give a regular course of clinical lectures and instruction in Morbid Anatomy. 4. The apothecary be legally qualified, either by having been in practice prior to the 1st of August, 1815, or by having received a certificate of qualification from this court. No dispensary will be recognised by the court unless it be situated in some town where there is a recognised medical school, and be under the care of at least two physicians and an apothecary legally qualified. No medical practice will be available unless it be attended in conformity with the course of study prescribed for pupils.

Names of Gentlemen having the Care of the Registers.

Birmingham: W. Sands Cox, Esq., Lecturer on Anatomy. Bristol: Dr. Wallis, and Henry Clark, Esq., Lecturers on Anatomy. Hull: Edward Wallis, Esq., Lecturer on Anatomy. Leeds: Thomas Nunneley, Esq., Lecturer on Anatomy. Liverpool: Dr. Malins, Medical Jurisprudence. Manchester: Thomas Turner, Esq., Anatomy. Newcastle: William Dawson, Esq., Midwifery. Sheffield: W. Jackson, Esq., Anatomy. York: John Hopps, Esq., Anatomy.

Registration of Testimonials.

All testimonials must be given on a printed schedule (a), with which students will be supplied at the time of their first registration:—

In London, at this hall.

In Edinburgh, Messrs. Mac Lachlan and Stewart's, booksellers.

In Dublin, at Messrs. Hodges and Smith's, booksellers.

In the provincial towns, from the gentlemen who keep the registers of the Medical Schools.

All students in London are required *personally* to register the several classes for which they have taken tickets; and those only will be considered as complying with the regulations of the court whose names and classes in the register correspond with their schedules.

Tickets of admission to Lectures and Medical Practice must be registered in the months of October and May; but no ticket will be registered unless it be dated within *seven* days of the commencement of the course; and certificates of attendance must be registered in the months of April and August. Due notice of the days and hours of such registration will be given from time to time.

(a) It is particularly requested that the lecturer himself will fill up the blanks in the schedule, specifying the mode of attendance.

The court also require students of the Provincial Medical Schols to register their names in their own handwriting, with the registrar of each respective school, within the first twenty-one days of October, and first fourteen days of May; and to register their certificates of having duly attended Lectures on Medical Practice within fourteen days of the completion of such attendance.

The registrars are requested to furnish the court of examiners with a copy of each registration *immediately* after its close, as those students only will be admitted to examination whose registrations have been *duly* communicated to the court.

Examination.

Every person intending to offer himself for examination must give notice in writing to the clerk of the society on or before the Monday previously to the day of examination, and must at the same time deposit all the required testimonials at the office of the beadle, where attendance is given every day, except Sunday, from ten until four o'clock.

The examination of the candidate for a certificate of qualification to practise as an apothecary will be as follows:—

(a) In translating portions of the first four books of Celsus de Medicinâ, and of the first twenty-three chapters of Gregory's Conspectus Medicinæ Theoreticæ.

In Physicians' Prescriptions, and the Pharmacopœia Londinensis.

In Chemistry.

In Materia Medica and Therapeutics.

In Botany.

In Anatomy and Physiology.

In the Principles and Practice of Medicine, including Midwifery and the Diseases of Children.

The examination of the candidate for a certificate of qualification to act as assistant to an apothecary, in compounding and dispensing medicines, will be as follows:

In translating Physicians' Prescriptions, and the Pharmacopœia Londinensis.

In Pharmacy and Materia Medica.

By the 22nd section of the Act of Parliament, no rejected candidate for a certificate to practise as an apothecary can be re-examined *until the expiration of six months* from his former examination: and no rejected candidate as an assistant *until the expiration of three months*.

The court meet in the hall *every Thursday*, where candidates are required to attend at a quarter before four o'clock.

The act directs the following sums to be paid for certificates.

For London, and within ten miles thereof, ten guineas.

For all other parts of England and Wales, six guineas.

Persons having paid the latter sum become entitled to practise in London, and within ten miles thereof, by paying four guineas in addition.

For an assistant's certificate, two guineas.

By an order of the Court,
HENRY BLATCH, Sec.

Apothecaries' Hall,
Aug. 1845.

UNIVERSITY OF OXFORD.

Full term is understood to begin on the first day of the week after the congregation has been held; so that, if the congregation be held on the Monday, the Sunday after is considered the first day of full term.

According to the lately altered statute respecting medical degrees, a candidate for the degree of Bachelor in Medicine, before he can be admitted to examination for that degree, must have kept four whole years, or sixteen terms, in the university, in like manner as is required by candidates for a degree in arts (b); must have passed the examination for the degree of bachelor in arts; and subsequently to that examination must have studied medicine

(a) By an order of the court, in future the Latin language will form part of the general examination.

(b) That is, he must be of sixteen terms' standing, and have actually *resided* in the university twelve terms.

during three whole years, or twelve terms; and must also have completed seven years, or twenty-eight terms, from his matriculation.

The medical examination takes place only once in the course of the year—namely, in the second week of full Trinity term, commencing usually on the *second Tuesday* after Trinity Sunday. The candidates are examined, principally "vivâ voce," but partly in writing, in the theory and practice of medicine, in anatomy, in physiology, pathology, and materia medica; and also in chemistry and botany, as far as they elucidate the art of medicine. He is required to be conversant with the entire works of Aretæus and Celsus, the aphorisms and epidemics of Hippocrates, and that portion of Galen's writings entitled "De usu Partium;" in two, at least, of which authors the statute directs that the ex[illegible] test the candidate's attainments [illegible] must [illegible] fourteen days before the day of examin[illegible] certificates of three years' attendance [illegible] ical practice of a hospital, with the [illegible] lectures.

Certificates are required for two courses of anatomy and physiology, each extending from October till the following April or May, two courses on the theory and practice of medicine, each course of the same extent; one course in materia medica, one course in botany, one course in chemistry, provided the course extend through the usual winter session, otherwise two courses will be required.

[illegible] candidate for the degree of doctor in medicine must have pursued the study of medicine during three years after he has graduated as bachelor in medicine, and must give at least a fortnight's previous notice of his intention to the professor of medicine, at the same time submitting to approbation a subject for a medical dissertation, which dissertation must be read in the public schools of the university within a few days of taking the degree of M.D., and delivered to the professor immediately after it has been read. No graduate in medicine from another university can be incorporated at Oxford unless he produce testimonials by which it may clearly appear that he has kept by residence terms equal to those required to be so kept in this university, he has completed all the exercises prescribed by the university from which he migrates for the degree of bachelor of arts, and shall have previously undergone the medical examination above described; and shall have fulfilled all the other con[illegible] of the present statute. The fees for a bachelor of medicine are £23; for a doctor in medicine £40.

The University of Oxford is in possession of the Bodleian library (librarian, B. Bandinel, M.A.); of the Radcliffe library (librarian, Dr Kidd); of the Ashmolean museum (keeper, P. B. Du[illegible]); and of [illegible] gardens, founded by the Earl of Danby in 1632. All these are open to students under cer[illegible] restrictions.

[illegible] Dr. Radcliffe left by will an endowment of £600 per annum, to be paid to two persons to be chosen out of the University of Oxford, so that they are M.A., entered on the study of [illegible], for their maintenance for ten years, and so [illegible] the half of which time, at least, they are to [illegible] in parts beyond sea, for their better improvement. In case of vacancy, by death, or at the expiration of the ten years, a new election is to take place within six months.

UNIVERSITY OF CAMBRIDGE.

Haviland delivers a course of fifty lectures on the principles of pathology and the practice of physic, £5 5s. first course, afterwards gratis. The professor of chemistry delivers thirty lectures, on the [illegible] principles of that science, during Lent term [illegible] lectures, principally on organic chemistry, during Easter term. Lectures on experimental philosophy, to illustrate the laws of hydrostatics, pneumatics, and optics, with particular reference to the mathematical theories of light and sound, are delivered in Easter term. Above fifty lectures on anatomy, by Dr. Clark, are delivered in Michaelmas and Lent terms. The terms of attendance are £5 5s. for each of two courses, afterwards gratis. The pupils have the opportunity of dissecting in private. Botanical lectures are given during the Easter term, with herborising excursions occasionally. Professor Willis's lectures on natural and experimental philosophy are during the Michaelmas term; the subjects being statics, dynamics, and mechanism, with their practical illustrations; first course, £3 3s.; second, £2 2s.; afterwards gratis. The Downing professor of physic delivers a course of fifty lectures on a medical subject. A certificate of attendance is required of persons proceeding to the degree of M.B. Lectures are also delivered on crystallography and mineralogy during the Lent term. Addenbrooke's hospital, which is connected with the university, is recognised by the Colleges of Physicians and Surgeons, and by Apothecaries' Hall. It contains 100 beds, and has a department reserved for cases of midwifery. The physicians are Dr. Thackeray, Dr. Bond, and Dr. Paget. Dr. Haviland [illegible] the consulting physician. The surgeons are Mr. Lestourgeon, Mr. Hammond, and Mr. Humphry. Mr Okes is the consulting surgeon.

A student, before he can become a bachelor of physic, must have entered on his sixth year, computed from the date of his first admission at the university, have resided nine terms, and have passed the previous examination.

A bachelor of arts may become a bachelor of physic after having entered on his sixth year, computed from the date of his first admission at the university, provided that one year at least has intervened between his final determination in arts and his admission to the degree of bachelor of [illegible]

The exercises for this degree are one act and one opponency.

Candidates for the degree of bachelor of physic must, in addition to the examination by the regius professor of physic, be examined by the professors of anatomy, chemistry, and botany, and by the Downing professor of medicine. This examination [illegible]st not take place before the fifth year after admission. They must have diligently att[illegible] the lectures of the regius professor of physic for two terms, and must bring to him certificates of examination by the above professors, and of attendance on their lectures, in case the course of lectures of the professor of botany consist of not less than twenty lectures, and the courses of lectures of the professors of anatomy and chemistry, and of the Downing professor of medicine, of not less than fifty lectures each. They must also deliver to the regius professor of physic certificates of having been diligently employed in attendance on medical lectures, and the practice of some well-known hospital, for two years, or for as long a time as they have been absent from the university [illegible] their undergraduateship. Fee, £10 16s.

A licence [illegible] granted to a bachelor of physic in the term subsequent to that in which he has taken the degree, or to a master of arts of two years' standing.

Candidates for a licence *ad practicandum in medicina*, being previously bachelors of physic, [illegible] required to produce to the regius professor of [illegible] certificates of their having attended hospital practice for three years, exclusive of the nine terms which they kept by residence for the degree of bachelor of physic, and of their having attended lectures on the following subjects: practice of physic and pathology, anatomy and physiology, chemistry, botany, medical jurisprudence, materia medica and pharmacy, principles of surgery, principles of midwifery, practical anatomy for two seasons.

Candidates for a licence *ad practicandum in medicina*, being previously masters of arts, are required to bring satisfactory evidence to the regius professor of physic of their having been employed in the study of physic for five years after they became bachelors of arts; and to produce to him certificates of their having attended on hospital practice for three of the said five years, and of their having attended lectures on the subjects before mentioned.

Every candidate for a licence *ad practicandum in* [illegible] is required to pass an examination to the satisfaction of the regius professor of physic, the professor of anatomy, the Downing professor of medicine, and a doctor of physic, to be nominated by the vice-chancellor, and approved by the senate, at the first congregation after the 10th of October in each year.

There are two such examinations in every year; one in the week immediately preceding that in which the division of the Michaelmas term falls; the other in the week immediately preceding that in which the division of the Easter term falls.

A candidate for a licence *ad practicandum in medicina*, being previously bachelor of physic, cannot be examined for the said licence until the examination which shall occur next but one after his having passed the examination required for the degree of bachelor of physic. Fee, £11 6s.

M.D.—The degree of doctor of physic is granted to a bachelor of physic of five years' or to a master of arts of seven years' standing.

The exercises for this degree are two acts and one opponency.

Every candidate for the degree of doctor of physic, who has not previously obtained a licence [illegible] *practicandum in medicina*, is required to produce to the regius professor of physic the same certificates, and pass the same examination, as are required in the case of candidates for a licence *ad practicandum in medicina*. Fee, £11 12s.

The university possesses an anatomical museum, to which has been added the valuable collection of the late Dr. Macartney, the Fitzwilliam, Mesman, Mineralogy, and Geological Museums, an extensive botanic garden, and the university library. To all these the students have access.

UNIVERSITY OF EDINBURGH. (1582.)

Matriculation.—Every student in the faculties of arts, law, and medicine, before entering with any professor, must produce a matriculation ticket for the ensuing session. Tickets will be issued at the matriculation office, in the college, every lawful day, from ten till three. Enrolment in the general album is the only legal record of attendance in the university.

Library. The library will be open for the purpose of giving out books to students, either on loan or for reference, in the hall appropriated for that purpose every lawful day during the winter session, from [illegible] a.m. till four p.m., except on Saturdays, when [illegible] will be shut at one precisely.

Every student applying for books must present to the librarian his matriculation ticket for the session, with the ticket of at least one professor.

Every book taken out must be returned within a fortnight, uninjured.

Fee for each course, £4 4s. For graduation, £25.

STATUTES OF THE UNIVERSITY OF EDINBURGH RELATIVE TO THE DEGREE OF M.D.

Sect. I. No one shall be admitted to the examinations for the degree of doctor of medicine who has not been engaged in medical study for four years, during at least six months of each, either in the University of Edinburgh, or in some other university where the degree of M.D. is given; unless in addition to three Anni Medici in an university, he has attended, during at least six winter [illegible], the medical or surgical practice of a general hospital, which accommodates at least eighty patients, and during the same period a course of practical economy, in which case three years of university study shall be admitted.

Sect. II. No one shall be admitted to the examinations for the degree of doctor who has not given sufficient evidence—1. That he has studied, once at least, each of the following departments of medical science, under professors of medicine, in this or some other university, as already defined—viz.:—

During Courses of Six Months.—Anatomy, chemistry, materia medica and pharmacy, institutes of medicine, practice of medicine, surgery, midwifery, and the diseases peculiar to women and children, general pathology, practical anatomy (unless it has been attended in the year of extra-academical study allowed by Sect. I.)

During Courses of Six Months, or Two Courses of Three Months.—Clinical medicine, that is, the treatment of patients in a public hospital, under a professor of medicine, by whom lectures on the cases are given.

During Courses of at least Three Months.—1. Clinical surgery, medical jurisprudence, botany, natural history, including zoology.

2. That in each year of his academical studies in medicine he has attended at least two of the six months' courses of lectures above specified, or one of these and two of the three months' courses. 3. That, besides the course of clinical medicine already prescribed, he has attended, for at least six months of another year, the medical or surgical practice of a general hospital, either at Edinburgh or elsewhere, which accommodates not fewer than eighty patients. 4. That he has attended, for at least six months, by apprenticeship or otherwise, the art of compounding and dispensing drugs at the laboratory of a hospital, dispensary, member of a surgical college or faculty, licentiate of the London or Dublin Society of Apothecaries, or a professional chemist or druggist. 5. That he has attended, for at least six months, by apprenticeship or otherwise, the out practice of a hospital, or the practice of a dispensary, or that of a physician, surgeon, or member of the London or Dublin Society of Apothecaries.

Sect. III. No one shall obtain the degree of doctor who has not studied, in the manner already prescribed, for at least one year previously to his graduation, in the University of Edinburgh.

Sect. IV. Every candidate for the degree in medicine must deliver, before the 24th of March of the year in which he proposes to graduate, to the Dean of the Faculty of Medicine—1. A declaration, in his own handwriting, that he is twenty-one years of age, or will be so before the day of graduation, and that he will not be then under articles of apprenticeship to any surgeon or other master. 2. A statement of his studies, as well in literature and philosophy as in medicine, accompanied with proper certificates. 3. A medical dissertation, composed by himself, in Latin or English, to be perused by a professor, and subject to his approval.

Sect. V. Before a candidate be examined in medicine, the medical faculty shall ascertain, by examination, that he possesses a competent knowledge of the Latin language.

Sect. VI. If the faculty be satisfied on this point, they shall proceed to examine him, either *viva voce*, or in writing,—1. On anatomy, chemistry, botany, institutes of medicine, and natural history bearing chiefly on zoology; and, 2. On materia medica, pathology, practice of medicine, surgery, midwifery, and medical jurisprudence.

Sect. VII. Students who profess themselves ready to submit to an examination on the first division of these subjects, at the end of the third year of their studies, shall be admitted to it at that time.

Sect. VIII. If any one, at these private examinations, be found unqualified for the degree, he must study, for another year, two of the subjects prescribed in Section II., under professors of medicine, in this or in some other university, as above defined, before he can be admitted to another examination.

Sect. IX. Should he be approved of, he will be allowed, but not required, to print his thesis; and, if printed, forty copies of it must be delivered, before the 25th day of July, to the Dean of the Medical Faculty.

Sect. X. If the candidate have satisfied the medical faculty, the dean shall lay the proceedings before the Senatus Academicus, by whose authority the candidate shall be summoned, on the 31st of July, to defend his thesis; and finally, if the senate think fit, he shall be admitted, on the first lawful day of August, to the degree of doctor.

Sect. XI. The Senatus Academicus, on the day here appointed, shall assemble, at ten o'clock a.m., for the purpose of conferring the degree; and no candidate, unless a sufficient reason be assigned, shall absent himself, on pain of being refused his degree for that year.

Sect. XII. Candidates for graduation shall be required to produce evidence of their having conformed to those regulations which were in force at the time they commenced their medical studies in an university.

JAMES SYME,
Professor of Clinical Surgery,
Dean of the Faculty of Medicine.
W. HAMILTON,
Secretary to the Senatus Academicus.

ROYAL COLLEGE OF PHYSICIANS, EDINBURGH.

The members of the college are respectively entitled Ordinary Fellows, Non-resident Ordinary Fellows, and Licenciates.

Ordinary Fellows.—No one shall be elected an ordinary fellow of the college till he has obtained the degree of doctor of medicine.

Every motion for the election of a fellow shall be made, at a quarterly meeting, by one of the fellows present, seconded by another, and determined by ballot—a majority of three-fourths being necessary to carry it in the affirmative.

No physician residing in Edinburgh shall be proposed for a resident fellowship till he has been a licentiate for nine months, or, in case of his not being a licentiate, till nine months after his petition to be admitted a resident fellow shall have been presented, unless an urgent reason be assigned; in this case, he may be proposed even on the same day on which he becomes a licentiate, or at any other quarterly meeting, or at a meeting specially called for the purpose, if this proposal shall be agreed to by every member present.

No fellow shall engage himself to any candidate before the ballot; nor shall he reveal to any person in what manner he did ballot, under the pain of being considered as one who has broken his faith and honour to the college.

No fellow shall take his seat in the college till the quarterly meeting after that on which he is elected, intimation to attend being then sent to him by the clerk.

The fellows shall be placed on the roll according to the dates of their admissions, and, when two or more fellows are admitted on the same day, they shall be entered on the roll according to the dates of their diplomas, and, if their diplomas be of the same date, they shall be enrolled according to their

Every fellow before taking his seat in the college must sign a promissory engagement.

It shall be in the power of any fellow of the college to move that a candidate having a foreign degree be admitted without a previous examination, and, if the motion shall be seconded, it shall be determined by ballot at next quarterly meeting, a majority of three-fourths of the fellows present being necessary to carry it.

If an examination shall take place, it shall consist of three trials: the first by two fellows appointed by the college, on any part of medicine; the second, by two other fellows, on two aphorisms of Hippocrates; and the third, by two other fellows, on two medical cases. All these trials shall be in the presence of the college, and in the Latin language.

Non-resident Fellows.—No physician residing in Edinburgh is eligible for a non-resident fellowship.

The mode of election of a non-resident fellow is the same as that of a resident-fellow; and the laws regarding examination, in the case of a foreign degree, also apply to him.

Fees.—The fee to be paid by a resident licentiate is £100.

The fee to be paid by a non-resident licentiate is £55.

The fees are exclusive of any tax payable to Government now existing, or which may hereafter be imposed.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.
(1505.)

Regulation for Fellows.—The candidate is required—To present an essay on some surgical subject, which, if approved of, he must print for circulation among the fellows. He must then undergo three examinations—1. On anatomy and surgery; 2. On chemistry, materia medica, &c.; 3. On the essay he has written. If these are satisfactorily passed, he is admitted to the fellowship. Fee, £250; to apprentices of fellows, £100.

School of Medicine.—Every candidate for a surgical diploma must have followed the course of study, to be specified afterwards, in a university; or at the seat of an established school of medicine, as defined below; or in a provincial school, specially recognised by the college.

Under the title, established school of medicine, are comprehended all places in this kingdom where diplomas in surgery are granted, and such foreign schools as are acknowledged by the constituted authorities of the countries in which they exist.

The extent and period of study allowed to be gone through at a provincial school will be regulated by the means and facility of study which the college receive evidence of its affording; but the lectures delivered at a provincial school will be held as qualifying for only one year's course of study, unless specially recognised for more.

Qualifications of Teachers.—The following classes of persons shall be entitled to give lectures, which may be attended as part of the course of study:—1. In the universities of Great Britain and Ireland, and in University College and King's College, London, the professors of these institutions. 2. In Edinburgh, resident fellows of the Royal College of Physicians of Edinburgh, and fellows of the Royal College of Surgeons of Edinburgh. 3. In London, fellows and licentiates of the Royal College of Physicians of London, and members of the Royal College of Surgeons of London, whose status as teachers has been admitted by that college. 4. In Dublin, fellows of King's and Queen's College of Physicians in Ireland, and members of the Royal College of Surgeons in Ireland. 5. In Glasgow, members of the Faculty of Physicians and Surgeons of that city. 6. In recognised provincial schools, teachers whose status as such has been admitted by the college, on special application. 7. In any of the above schools, teachers, who, having acquired a status as such in one of the four established schools, in conformity with the above regulations, shall have been subsequently admitted, on application to the college, to the enjoyment of the same privileges in another school. (a)

The following branches of instruction may be conjoined:—Anatomy and practical anatomy, chemistry and practical chemistry, practice of medicine and clinical medicine, practice of surgery and clinical surgery, mathematics and mechanical philosophy; and, for the present, clinical medicine or clinical surgery may be taught in conjunction with any one of the other courses of education prescribed in the curriculum, by a physician or surgeon qualified according to the regulations of the college, and attached to a public hospital of the size which these regulations prescribe.

Course of Study. Preliminary Instruction.—Every candidate for the diploma of the Royal College must, either previously to or during his medical education, have received regular instruction in the elements of mathematics; and must have subsequently attended a course of mechanical philosophy of at least three months' duration, and of not fewer than sixty lectures.

Professional Instruction. The candidate must have been engaged in attending the following separate and distinct courses of lectures during a period of not less than twenty-seven months, in which must have been included three winter sessions of six months' duration each. Anatomy, twelve months. Chemistry, one course of six months. Practical chemistry (the number of pupils in each class being limited to twenty-five), one course of three months. Materia medica and pharmacy, one course of six months. Practical pharmacy, one course of six months. Institutions of medicine, or physiology,

(a) The only lectures expected from this law are those on mechanical philosophy and on chemistry. The former may be professors in universities, lecturers in public institutions, or teachers specially recognised by the college; and the latter may be persons not medical, if recognised by the college on special application, in conformity with a resolution of the college on the 25th October, 1838. In all cases of special recognitions, proof of capability, and of the applicant possessing the requisite apparatus for illustrating his lectures, will be required.

one course of six months. Practice of medicine, one course of six months. Clinical medicine, one course of six months, or two courses of three months each, during the period of his attendance at the hospital where they are delivered. Principles and practice of surgery, two courses of six months each, or, principles and practice of surgery, and military surgery, one course of six months each. Clinical surgery, one course of six months, or two courses of three months each, during the period of his attendance at the hospital where they are delivered. Midwifery and diseases of women and children, one course of three months. Medical jurisprudence, one course of three months.

The six months' courses delivered in Edinburgh must consist of not fewer that 110 lectures, with the exception of clinical medicine, clinical surgery, and military surgery. The three months' courses must consist of not fewer than sixty lectures. Two London courses of three months each on any of the above subjects will be taken as equivalent to one six months' course.

The candidate must also have attended for twenty-one months a public general hospital containing at least eighty beds.

Fees payable by Candidates.—For a diploma, ordinary candidates pay the sum of £7 5s. (Apprentices of fellows of the Royal College, bound for the freedom, pay 25s.; their other apprentices pay £2 16s. 6d. Assistant-surgeons in the navy, having previously obtained certificates from the college, pay £2 11s. 6d. Surgeons in the navy, having obtained certificates from the college, pay 15s. 6d.)

For the certificate of qualification to act as assistant-surgeon in the navy, candidates not having paid for any previous qualification pay £4 19s. 6d.

For the certificate of qualification to act as full surgeon in the navy, assistant-surgeons who have already obtained certificates from the college pay £3 18s. 6d., and those who have previously obtained the diploma of the college pay £2 17s. 6d.

UNIVERSITY OF GLASGOW.—REGULATIONS REGARDING DEGREES IN MEDICINE AND SURGERY TO CANDIDATES ENTERING THE UNIVERSITY IN, OR SUBSEQUENT TO, 1839-40.

Medicine.—Every candidate for a medical degree must lodge with the clerk or senate—

1. A certificate of moral character, by two respectable persons, with evidence of having attained the age of twenty-one.

2. Evidence of having attended, for four years, a university in which medicine is regularly taught, or medical lectures delivered in London or Dublin; and at least one year of the four must be spent at the University of Glasgow. In each year he must have attended at least two courses of lectures of six months' duration; but if he shall spend one year only at the University of Glasgow, then he must attend three courses of lectures delivered there, two of them, at least, being of six months' duration.

3. Certificates of having attended one or more courses of lectures on the following subjects, each course, except forensic medicine and botany, being of six months' duration; if of less extent, then two courses shall be deemed equivalent to one of six months:—Anatomy and physiology; chemistry; the theory or institutes of medicine; practice of medicine; materia medica and pharmacy; midwifery; surgery; forensic medicine; botany (a); anatomical dissections; and two years' practice of a general hospital, containing eighty beds, and in which the student must spend at least one-half of the period of attendance in the physicians' wards. Neither hospital attendance nor anatomical dissections shall be considered as equivalent to a course of lectures.

4. Each candidate must lodge with the clerk of senate, with the above certificates, a schedule of his course of study, properly filled up, together with an English essay on some medical subject chosen by himself, two months before the time of graduation—that is, on or before the 1st of March, or the 10th of June, yearly, otherwise he cannot be admitted for examination till the following term. All tickets of attendance lodged by candidates must be certified, not excepting those of the current session; but the certified botanical tickets of the current session shall not be received until the 1st of April.

(a) No course of botany attended previously to 1839-40 is received, unless it shall have been delivered in a university.

No student entered in any medical class later than the 1st of December, without special permission of the senate. And it is strictly required of every candidate for graduation that he produce evidence of his name having been enrolled in the library-book, on or before that day, as well as an express certificate of his regular attendance by each professor on whose lectures he attends. In order, further, to ensure attendance, all students must inscribe their names, once a fortnight, in a register kept for the purpose, stating the lectures, &c., which they attend.

6. Every candidate shall prove that he has a competent knowledge of Latin, and shall undergo full examinations on all the subjects included in the curriculum.

Surgery.—The regulations respecting certificates of age and moral character are the same as those under the head of degrees in medicine.

Candidates for the degree of master of surgery shall produce evidence that they have attended medical lectures in one or other of the universities or schools already specified for four years, during which they must have attended one or more courses on the following subjects, the extent of each course, with the exception of forensic medicine, being six months, or the equivalent two courses of a shorter duration. The candidate must have attended not less than three courses of medical lectures in the University of Glasgow. In each year of his study he shall have attended at least two or more courses of lectures, of six months' duration, on anatomy, surgery, chemistry, theory or institutes of medicine, practice of medicine, midwifery, materia medica and pharmacy, forensic medicine, anatomical dissections, and two years' practice of a general hospital, in which the student must attend one-half of the prescribed period in the surgical wards, and the other half in the medical.

The regulations as to lodging certificates of attendance, and an essay in English, and as to the candidate's knowledge of Latin, are the same as under the head of medical degrees, only the essay is to be on a surgical subject. The days of graduation are the last Wednesday of April and the first Wednesday of August.

Fee to the library, &c., for the degree of M.D.	£15	0	0
Duty on stamp for ditto	10	3	0
	£25	3	0
Fee for the degree of Chirurgiæ Magister	£10	10	0

N.B. Candidates for degrees who attended classes in the University of Glasgow previously to 1839-40 admitted to examination, according to the regulations which existed at the time when they began to study medicine.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

Regulations for the Surgical Diploma.—The faculty recommend that candidates should attend elementary courses of study in mathematics and natural philosophy. These branches, however, are not imperative. Every candidate's knowledge in Latin should be tested at his examination, by being required to construe some part of Gregory's Conspectus Medicinæ Theoreticæ.

Curriculum.—Anatomy, two courses of six months. Practical anatomy, one course of six months; enacted 7th June, 1830. Surgery, two courses of six months. Chemistry, one course of six months. Practical chemistry, one course of three months; enacted 8th November, 1831. Theory of medicine, one course of six months. Practice of medicine, one course of six months. Materia medica, one course of six months. Midwifery, one course of six months. Clinical medicine, one course of six months; enacted 7th June, 1830. Clinical surgery, one course of six months; enacted 7th June, 1830. Medical jurisprudence and police, one course of six months; enacted 4th April, 1841. Botany, one course of three months; enacted 3rd February, 1834. A public hospital, eighteen months; enacted 3rd February, 1834. A surgeon's or apothecary's shop, six months; enacted 3rd February, 1834.

The above lectures must have been delivered by professors or lecturers in an university; or by resident members of the Royal Colleges of Physicians or Surgeons respectively of London, Edinburgh, or Dublin; or by means of the faculty. Every candidate must have been employed in the above course of studies for four winter sessions, or for three winter sessions and two summer sessions, so that the whole period of attendance shall not be less than three years complete. An essay, the subject to be fixed by the examiners, to be written by the candidate, in his own handwriting; and no essay to be submitted for a shorter period than 24 hours. Specimens of bones, or other anatomical or surgical preparations, or specimens from the materia medica, shall be used at the discretion of the examiners. The fee of seven guineas shall be deposited with the president previous to the examination, and at the same time satisfactory documents shall be produced that the above curriculum of education has been duly completed by certified attendance.

N.B. These branches, whose dates are specified, are not required by those students who commenced their studies anterior to these enactments. The commencement of education is ascertained by the date of the first ticket.

The fees for the diploma are £7 7s. The president, visitor, collector, box-masters, and seal-keeper, form, along with the assistant-examiners, the examining court. The diploma of the faculty is recognised by all the licensing bodies in the three kingdoms, and by the poor-law commissioners in England and Ireland.

KING'S COLLEGE, ABERDEEN.—REGULATIONS TO BE OBSERVED IN GRANTING DEGREES IN MEDICINE AT KING'S COLLEGE.

All candidates for the degree of M.D. must be of the age of twenty-one years, and must produce satisfactory certificates of moral character, and exhibit the diploma of A.M. from some university.

All candidates, with the exceptions mentioned below, must have been engaged in the study of medicine for at least four years, one of which must be passed in Aberdeen, and must produce evidence of having attended, in some recognised school of medicine, the following courses of lectures:—Six months' courses: anatomy, two courses; chemistry, one course; materia medica, one course; surgery, one course; institutes of medicine and physiology, one course; practice of medicine, one course; midwifery, one course. Three months' courses: dissections, two courses; practical chemistry, one course; medical jurisprudence, one course; clinical surgery, one course; botany, one course; clinical medicine, two courses.

In addition to the above, the candidate must have attended for two years the wards of a hospital containing 100 beds; and, during three months, a shop or dispensary for the compounding of medicine.

The preceding regulations are strictly enforced in the case of all students who shall commence their medical studies at a period subsequent to 1st October, 1840. But gentlemen who possess a licence or diploma from any of the royal colleges of physicians or surgeons, and who have been engaged for at least five years in the practice of medicine, may be admitted to examination on producing their licence or diploma, along with satisfactory evidence of sufficient preliminary education and of good moral character.

Previously to examination each candidate must lodge with the secretary £26 5s. 6d., the same to be returned to him should he not obtain his degree.

Degrees in medicine are conferred at two stated periods annually—viz., at the end of April, and at the end of July.

REGULATIONS FOR GRANTING MEDICAL DEGREES IN MARISCHAL COLLEGE AND UNIVERSITY, ABERDEEN.

Curriculum.—Four years of attendance on medical classes, of which one year may be passed at any recognised medical school; but three, at least, must be passed in a university, including one, at least in this university. The attendance, in each year,

to embrace not fewer than two medical classes of six months each; or one of six months, with two or three months each. But it will be held equivalent to *one* of four years of such attendance in a university—1st, in a master of arts, to have attended one medical class while passing through the curriculum of arts; or, 2ndly, in any student, to have attended a medical class, in each of two years, along with classes in the curriculum of arts. The university attendance to include the following eight classes, each for a course of six months:—Anatomy, practical anatomy, chemistry, materia medica, institutes of medicine, surgery, practice of medicine, midwifery, and the following three classes, each for a course of three months—botany, practical chemistry, medical jurisprudence.

Eighteen months of attendance on the medical and surgical practice of a hospital containing not fewer than eighty beds, along with attendance for six months on lectures on clinical medicine, and for three months on lectures on clinical surgery.

Six months of compounding and dispensing medicines in the laboratory of a hospital, or of a public dispensary, or of a licensed general practitioner, or of a regular dispensing druggist.

Exemption to Practitioners.—It will be held equivalent to the curriculum prescribed in the three foregoing regulations to have obtained, upon examination, a diploma or a licence, in medicine or in surgery, from a university or other authority established by law within the United Kingdom, and to have subsequently attended medical classes in this university during one winter session.

Examinations.—The examination terms to be two in each year—the *first* to commence on the 20th of April, if a Wednesday, but if not, on the first Wednesday thereafter; the *second* on the 13th of October, if a Wednesday, but if not, on the first Wednesday thereafter.

Every candidate to undergo at least three separate professional examinations—the first, pharmaceutical; the second, surgical; the third, medical; to be conducted partly in writing, as well as *vivâ voce*, and partly by demonstration. The *first* to include chemistry, botany, materia medica, pharmacy, and the doctrines of physics relating to specific gravities, to gases and vapours, and to climate. The *second* to include anatomy, institutes of medicine, surgery, and the doctrines of chemistry and physics illustrative of animal structure and function. The *third* to include the practice of medicine, midwifery, and medical jurisprudence.

Every candidate not a master of arts must undergo a preliminary examination on the Latin language (the book to be used being *Celsus de Medicina*), and on the etymology of such terms in the medical sciences as are derived from the Latin and the Greek.

Any candidate that so desires shall be admitted to each one, or to any two, of his three professional examinations, at different terms; but not to the first examination until the begining of his third year of medical classes; nor to the second until the end of his third year; nor to the third until the end of his fourth year, and until he be twenty-one years of age; nor shall a greater interval than eighteen months be allowed between two successive professional examinations without a full renewal of the previous one or two. The preliminary examination must be passed at the same term as the first professional examination.

In order to be received for examination, certificates must have been lodged with the professor of medicine on the first day of the month of the examination term, showing that the candidate is of the required age, that he is of good moral character, and that he has passed through the requisite course of professional education. Along with such certificates must be lodged a schedule, filled up in his own handwriting, containing a list of them, and specifying such additional branches of education, professional and general, as he may have studied.

UNIVERSITY OF ST. ANDREW'S. (1412.)—REGULATIONS FOR GRANTING MEDICAL DEGREES.

The candidate must produce evidence of unexceptionable moral character, and before being admitted to examination must subscribe a declaration that he is twenty-one years of age.

The candidate must have had a liberal and classical education, and, if he be not in the possession of the degree of A.M., must be ready to undergo an examination as to his proficiency in the Latin language.

The candidate must produce certificates that he has regularly attended lectures delivered by professors in some university, or by resident fellows of the Royal Colleges of Physicians or Surgeons of London, Edinburgh, Glasgow, Aberdeen, or Dublin, for at least four complete winter sessions, or three winter and three summer sessions, on the following branches:—1, anatomy, two courses of six months each; 2, practical anatomy, twelve months; 3, theory of medicine, or physiology, one course of six months; 4, chemistry, one course of six months; 5, practical chemistry, one course of three months; 6, materia medica and pharmacy, one course of six months; 7, surgery, one course of six months; 8, clinical medicine, one course of six months; 9, practice of medicine, one course of six months; 10, clinical surgery, one course of six months; 11, midwifery, and diseases of women and children, one course of three months; 12, an apprenticeship, or six months' attendance in the shop of an apothecary, or in the laboratory of a public hospital or dispensary; 13, attendance at a public hospital, containing not less than eighty beds, for at least eighteen months.

These regulations will be invariably observed, except when the candidates are possessed of a surgeon's diploma or licence from the Colleges of London, Edinburgh, or Dublin, or the Faculty of Physicians and Surgeons of Glasgow, or a licence from the Apothecaries' Company, in which case they have merely to present such diploma or licence previous to their examination for M.D.

UNIVERSITY OF DUBLIN (TRINITY COLLEGE). 1591

Chancellor, his Majesty the King of Hanover; *Vice-Chancellor*, his Grace the Lord Primate of Ireland; *Provost*, Dr. Sadleir.

The days of graduation are, Shrove Tuesday, and the first Tuesday in July. The degree of bachelor of medicine may be obtained in two modes:—

1. Graduates in arts can obtain the degree at any of the half-yearly periods of graduation, provided the requisite medical education and examination shall have been accomplished. Fee for entrance, £16; fees for study in arts during four years, £7 10s. each half year; fees for graduation in arts, £8 17s. 6d.

2. Candidates are admissible to the degree of M.B., without previous graduation in arts, at the end of five years from the July following the Hilary examination of the first undergraduate year, provided the usual education and examinations in arts of the first two years of the undergraduate course shall have been completed, as also the medical education and examinations, as in the case of other candidates. Fees for two years' study in arts (besides the usual entrance payment of £16) are £7 10s. each half year. The graduation fees for the degree of bachelor of medicine are £11 15s. The standing of the first undergraduate year may be obtained by attending the October examination of that year, if the student has entered not later than the first Monday of the July of the same year, and has completed the payments due since the ordinary period of entrance in the preceding November. The medical education of a bachelor of medicine comprises attendance on the following courses of lectures in the school of physic established by act of parliament, provided that one, and not more than three, of the courses which begin in November be attended during each of four sessions. Three of these courses, at the discretion of the candidate, may be attended at the University of Edinburgh. The courses are on—anatomy and surgery, chemistry, botany, materia medica and pharmacy, institutes of medicine, practice of medicine, midwifery (by the professor to the College of Physicians), clinical lectures at Sir Patrick Dun's Hospital, during at least one session (six months), as delivered by the professors in the school of physic; the attendance on such clinical lectures by the professors to be extended to three additional months of a summer session commencing in May. This regulation to affect all students commencing their medical studies after 17th July, 1841, and to be in lieu of attendance on the hospital from 1st May to the 1st November following. The fees for attendance on the clinical lectures are £3 3s. to the professors for each three months' attendance, and (provided the student be of two years' standing in the university) £3 3s. to the treasurer of the hospital for the first year, with a proportionate sum for any longer period. The fee for each of the other courses is £4 4s. The examinations are conducted by the regius professors of physic of the university, the six professors of the school of physic, and the professor of midwifery to the King and Queen's College of Physicians. No further examination is requisite for the degree of doctor of medicine, which may be taken at the expiration of three years from having taken the degree of M.B., provided the candidate shall have graduated in arts. The fees for the degree of doctor of medicine are £22. The degrees are publicly conferred by the vice-chancellor, in the senate or congregation of the university.

COLLEGE TERMS.

Hilary begins January 10, ends March 25.
Trinity " April 15, " June 30.
Michaelmas October 10, " December 20.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

Qualifications of Candidates for License.—Candidates must produce evidence of having been engaged in the study of medicine for four years, and of having attended two at least of the required courses in each year. Candidates, except those who have taken a medical degree prior to 1840, must produce certificates of attendance on one or more courses of lectures on the following subjects, each course being of six months' duration, with the exception of botany and forensic medicine, which must include at least fifty lectures:—Anatomy and physiology, chemistry, materia medica and pharmacy, botany, institutes of medicine, practice of medicine, principles and practice of surgery, midwifery, and forensic medicine. The lectures on anatomy, chemistry, botany, materia medica, institutes of medicine, and practice of medicine are required to have been delivered by the respective professors of the school of physic in Dublin, or in an university. The lectures on surgery are required to have been delivered on at least three days in the week, during four months, by a professor of surgery in an university or college of physicians or surgeons in the United Kingdom, or by the surgeon of a medico-chirurgical hospital recognised by the college. These lectures must not form a part of a course of lectures on anatomy. The lectures on midwifery are required to have been delivered by a professor of midwifery in the university or college of physicians or surgeons in the United Kingdom, or by the master of the lying-in hospital, Dublin. The lectures on medical jurisprudence are required to have been delivered by a professor in an university or college of physicians or surgeons in the United Kingdom. Certificates must also be produced of six months' attendance on anatomical demonstrations and dissections, and of at least two years' hospital practice; one year in the hospital of the school of physic in Dublin or Edinburgh, the other in any recognised medico-chirurgical hospital. The certificates must include attendance on the entire practice of the hospital, and on all the clinical lectures delivered in the hospital during such attendance. Candidates who have taken a medical degree in an university shall be admitted to examination upon such degree alone. Every candidate for licence, except those who have taken a medical degree prior to 1840, is examined on two separate days; on the first day on anatomy and physiology, chemistry, botany, materia medica, and pharmacy; and on the second day on acute and chronic diseases, midwifery, and non-naturals, and on the translating of one or more of the following books from the original Greek, viz.: Hippocrates, Aretæus, and Galen. Graduates in medicine are only required to undergo the second day's examination. The examinations, which are public, are conducted in the English language; but every candidate, except graduates in arts at Oxford, Cambridge, or Dublin, is required to translate medical cases from the English into the Latin language,

before he is admitted to examination as to his professional acquirements. Fee for license, £30.

The license of this college is equivalent to a medical degree, and it confers privileges which a degree does not.

The fellows are chosen from the licentiates of three years' standing; they are required by statute (40 Geo. III., cap. 84, sect. 42) to have taken the degree of M.D. in one of the universities of Dublin, Oxford, or Cambridge; or to have taken the degree of A.B. in one of these universities, and to have received the medical education requisite for obtaining the license, for which a degree in medicine is not necessary. Fee to the college, on election to the fellowship, £20, with an additional stamp duty of £25.

The act of parliament provides that these qualifications may be dispensed with whenever, at any time, the number of fellows is reduced to six.

The college has the power of conferring the honorary fellowship on any of its own licentiates who have not the statutable qualifications; on such of its fellows as resign or vacate the fellowship; and on such eminent medical men, not licentiates, as it may wish to distinguish by its approbation.

ROYAL COLLEGE OF SURGEONS IN IRELAND.
(1784- -1828.)

By-laws respecting the Registry of Pupils.—Every person requiring to be registered as a pupil on the college books shall be so registered, if he shall have laid before the court of censors the following documents, viz.:—

Provided he be an apprentice, and shall have paid any apprentice fee: 1. A receipt showing he has lodged, to the credit of the president, and for the use of the college, in the Bank of Ireland, the registry fee of te [illegible] 2. A receipt showing that the member or licentiate to whom he is indentured has lodged a similar sum of ten guineas. 3. A declaration, subscribed by the member or licentiate to whom he is indentured, stating that he has really and *bona fide* received the usual fee of one hundred and fifty guineas, or value to that amount. 4. His indenture of apprenticeship, duly executed, and bearing the requisite stamp.

Provided he be an apprentice, and shall not have paid an apprentice fee, he shall lay before the court: 1. A declaration, subscribed by the member or licentiate to whom he is indentured, that he has not received, or that he does not expect to receive, any apprentice fee. 2. A receipt, showing that he has lodged, to the credit of the president, and for the use of the college, in the Bank of Ireland, the sum of fifty guineas. 3. His indenture of apprenticeship, regularly executed and registered.

Provided he be an apprentice, and be the son, brothers or nephew of the member or licentiate to whom he is indentured, or the son of some other member or licentiate of the college, and shall not have paid an apprentice fee, he shall lay before the court: 1. A declaration, subscribed by the member or licentiate to whom he is indentured, that he has not received, or that he does not expect to receive, any apprentice fee. 2. A receipt, showing that he has lodged, to the credit of the president, and for the use of the college, in the Bank of Ireland, the sum of ten guineas.

Provided he shall not be an apprentice to a member or licentiate of the college. 1. A receipt, showing that he has lodged, to the credit of the president, and for the use of the college, in the Bank of Ireland, the registry fee of ten guineas.

By-laws relating to Education and the Qualification of Candidates for Letters Testimonial.—Every registered pupil or apprentice shall be admitted to an examination for letters testimonial, if he shall have proved and showed that his professional education has been, in all respects, comformable and agreeable to the provisions and enactments of the by-laws and rules of the college, and shall have laid before the court the following documents:—1. A receipt, showing that he has lodged, as a registry-fee, the sum of ten guineas in the Bank of Ireland, to the credit of the president, and for the use of the college, previously to his being admitted to any examination. 2. A receipt, showing that he has lodged a sum of twenty guineas in the Bank of Ireland to the credit of the president, and for the use of the college, previous to his final examination for letters testimonial. 3. A certificate, signed by the president or vice-president, and two of the court of censors, that he has passed an examination as to his acquaintance with the Greek and Latin languages. 4. Certificates, showing that he has been engaged in the study of his profession for not less than four years, three of which shall have been passed in attendance on lectures or hospitals, during the winter sessions, in Dublin, London, Edinburgh, or Glasgow. 5. Certificates of attendance on a surgical hospital where clinical instruction is constantly given, containing fifty patients at least, for a period of not less than twenty-four months. 6. Certificates of attendance on the medical practice of a recognised hospital or dispensary, where clinical instruction is constantly given during twelve months. 7. Certificates of attendance on three courses of lectures on anatomy and physiology, three courses of lectures on the theory and practice of surgery, and of the performance of three courses of dissections, accompanied by demonstrations; also certificates of attendance on two courses of lectures on chemistry, or one course of lectures on general, and one on practical, chemistry; one course of lectures on materia medica; one course of lectures on the practice of medicine; one course of lectures on midwifery, and one course of lectures on medical jurisprudence. 8. A thesis, essay, or dissertation, in Latin or English, on any of the following subjects:—Anatomy, physiology, surgery, the practice of medicine, chemistry, materia medica, midwifery, or medical jurisprudence; or, in the place of such dissertation, a series of cases collected in the hospital in which the candidate has attended, illustrated by comments or observations.

A candidate, being a registered pupil, shall be allowed to pass the first of the two days' examination above mentioned, on anatomy and physiology, on laying before the court of censors the following documents:—1. A receipt, showing that he has lodged a sum of ten guineas in the Bank of Ireland, to the credit of the president, and for the use of the college. 2. Certificates, showing that he has been engaged in the study of his profession for not less than three winter sessions in Dublin, London, Edinburgh, or Glasgow. 3. Certificates of attendance on three courses of lectures on anatomy and physiology, and of the performance of three courses of dissections, accompanied by demonstrations, such candidate not being admissible to the second day's, or the final, examination, on the other subjects above specified, until he shall have lodged a further sum of ten guineas in the Bank of Ireland, to the credit of the president, and for the use of the college, and shall have laid before the court of censors all the documents enumerated in the by-laws relative to "qualifications for the letters testimonial." Notice of every examination for letters testimonial is posted in the hall, and the secretary also, by regular summonses, gives notice of such examination to the members resident in Dublin. The examination takes place in the presence of such members and licentiates as choose to attend. The candidate is examined on two several days in anatomy and physiology, on the practice of medicine and surgery, and on any other branch of medical science, and shall perform such surgical operations or dissections, and explain such anatomical preparations, as the court may require.

Fee for letters testimonial or diploma, £31 10s.; and for admission as member (which takes place by ballot after three years' standing as a licentiate, and confers corporate rights), £31 10s.

APOTHECARIES' HALL OF IRELAND. 1791.

Laws regarding the Education of Apothecaries.—Every candidate must undergo two separate examinations—one for the certificate of apprentice, the other for the licence to practise.

Every candidate for the certificate of apprentice must have attained the age of fifteen years, and will be examined in the following books:—The works of Sallust; the first six books of the Æneid of Virgil; the Satires and Epistles of Horace; the Greek Testament; the dialogues of Lucian; the first four books of Homer's Iliad; the first six books of Telemachus, or the history of Charles the Twelfth (in French); the first two books of Euclid; and algebra—to simple equations.

Every candidate for the licence to practise as an apothecary must lay before the court the following documents:—1. The certificate of apprentice. 2. The indenture of apprenticeship, enrolled according to the act of parliament and bearing the certificate of the licentiate apothecary to whom he has been indented, that he is of good moral character, and has fulfilled the period of his apprenticeship. 3. Certificates duly signed that he has diligently attended at least one course of lectures on each of the following subjects, delivered at the school of Apothecaries' Hall, or at some other school of medicine recognised by the court (the order of the study here laid down is recommended for the guidance of students):—Chemistry, anatomy and physiology, six months; practical chemistry and botany, three months; materia medica, demonstrations, and dissections, theory and practice of physic, surgery, midwifery, and the diseases of women and children, six months; medical jurisprudence, three months.

A certificate of twelve months' attendance on the entire practice of a medico-chirurgical hospital, recognised by the court, containing not less than fifty beds, and where clinical instruction is regularly given.

Also, a certificate of having assisted in at least thirty cases of midwifery practice, twenty of which must be attended in a recognised hospital.

The examination for the licence to practise as an apothecary will be as follows:—In translating and explaining the process of the British pharmacopœias and extemporaneous prescriptions; in chemistry and general physics; in materia medica and therapeutics; in natural history and medical botany; in anatomy and physiology; in the theory and practice of medicine; in midwifery; in medical jurisprudence.

The examination for the licence to act as assistant to an apothecary in compounding and dispensing medicine will be confined to the following subjects:—To translate the Dublin pharmacopœia, and extemporaneous prescriptions; pharmacy, botany, materia medica, and mechanical philosophy.

The candidate for the assistant's licence may present himself for examination at the termination of five years' apprenticeship.

The court of examiners sit every Friday, at two o'clock, and proceeds with the examination of candidates, in the order in which their names appear on the list.

A rejected candidate cannot be re-admitted to examination until the expiration of six months, and, after a second rejection, can appeal to be examined by the King and Queen's College of Physicians.

All lecturers are required to furnish the court of examiners with a list of such gentlemen as have taken out admission tickets on or before the first day of January; also a similar list of those who have obtained certificates of having attended their respective courses, with the number of lectures in each course, on or before the 10th May, annually.

REGULATIONS OF THE ARMY MEDICAL DEPARTMENT, 13, ST. JAMES'S-PLACE.

Director-General, Sir James M'Grigor, Bart., M.D. (1815). Deputy Inspectors-General of Hospitals, Dr. Gordon (1836), and Dr. Clarke, assistant staff-surgeon. Apothecary, Francis Bassano (1825). Commissioned for Ireland only: Director-General, Dr. Renny (1795). Deputy Inspectors-General, Dr. Peile, Dublin (1803); Sir James Pitcairn, M.D., Cork, 1803.

A candidate for an assistant-surgeoncy in the army is required to fill up a blank form of certificate, which may be obtained at the office by written application to the director-general, specifying by whom he is recommended, his Christian and surname at full length, with the course of study he has pursued. The candidate is, in addition, to sign and forward the following declaration:—

"I [Christian and surname at full length],...... years of age, a candidate for employment in the medical department of the army, do hereby attest my readiness to engage for general service, whether at home or abroad, and to proceed on duty immediately on being gazetted. I declare my age not to exceed twenty six years, that I am unmarried, and that I labour under no mental or constitutional

disease, nor physical disability, that can interfere with the most efficient discharge of the duties of a medical officer in any climate." [Signature] . . .

In selecting from among the candidates for the medical department of the army, a preference is given to those who can fill up all the blanks in the printed form; but the name of no gentleman can be placed on the list who does not possess the diploma of either of the colleges of surgeons of London, Edinburgh, or Dublin, and who cannot produce the following testimonials:—Eighteen months' attendance at an hospital of celebrity, where the average number of in-patients is not less than one hundred; twenty-four months' anatomy; twelve months' practical anatomy; twelve months' surgery, or (what is preferred) six months' surgery, and six months military surgery; eight months' clinical surgery, a complete course of two or three lectures during the week; twelve months' practice of physic, or six months of practice of physic, and six months of general pathology; eight months' clinical lectures on ditto, the same as required in surgery; twelve months' chemistry; six months' practical chemistry; three months' botany; four months' materia medica; three months' practical pharmacy, or apprenticeship; five months' natural history; five months' midwifery; five months' natural philosophy.

The candidates must be unmarried, not beyond twenty-six years of age, nor under twenty-one years.

Candidates who have had an university education, and have the degree of A.B. or A.M., as well as that of M.D., will be preferred; but a liberal education, and a competent knowledge of the Greek and Latin languages, are indispensably requisite in every candidate; and the greater the attainments of the candidates in various branches of science, in addition to competent professional knowledge, the more eligible will they subsequently be deemed for promotion in the service; for selections to fill up vacancies will be guided more by reference to such acquirements than to mere seniority. Before promotion from the rank of assistant-surgeon to any higher rank, every gentleman must be prepared for such other examination as may be ordered before a board of medical officers.

Although the British schools are specified, it is to be understood that candidates who have received regular education in approved foreign universities or schools will be admitted to examination.

With the exception of practice of physic and clinical medicine by one teacher, candidates must have attended separate lectures for each branch of the science. The certificate of the teacher of practical anatomy must state the number of subjects or parts dissected by the pupil. Certificates of lectures and attendance must be from physicians or surgeons of the recognised colleges of physicians and surgeons of the United Kingdom, or of foreign universities. A certificate that the candidate is acquainted with the art of cupping is required.

Diplomas, tickets of attendance on lectures, and certificates of regular attendance by each professor or lecturer, must be lodged at this office for examination and registry at least one week before the candidate appears for examination, and likewise certificates of moral conduct and character, one of them by a clergyman, and that of the parochial minister is desirable. Baptismal certificates are required at the same time; if the parish register cannot be resorted to, an affidavit from one of the parents, or some person who can attest the fact, will be accepted.

All communications to be forwarded "unsealed," under cover, to "the Right Honourable the Secretary at War," with the words "Army Medical Department" at the corner.

Although, in the examination of candidates, gentlemen are expected to be qualified in every branch of study required, they are requested to be particularly coversant in the knowledge of—1. Tropical diseases, and the diseases to which soldiers are most liable. 2. Military surgery, and works on the habits of soldiers and rules of the service. 3. Cullen's Nosology, being that adopted in all returns and reports. 4. Willan's Classification of Cutaneous Diseases. 5. The latest authors on the diseases of the eye. They are expected readily to translate a passage from a Greek or Latin author; to be conversant with Baillie and the later author morbid anatomy; with Cullen's, Mason Good's, and Gregory's Practice of Physic, the latter giving an account of tropical diseases, and those most commonly met with in the army; with the works of Hunter, Hennen, Dr. John Thomson, Guthrie, Samuel Cooper, Millengen, Ballingall, Marshall, and Baron Larrey, on Military Surgery; with the works of Chisholm, Bancroft, Lind, Blane, Burnet, Johnstone, and Annesley, on the Diseases of Warm Climates; but Baillie's Morbid Anatomy, Hennen's and Ballingall's Military Surgery, 3rd edition, with his valuable work on Medical Topography, Guthrie on gun-shot wounds and on the eye, and Gregory's Practice of Physic, should form part of the baggage of every military surgeon.

Candidates, after passing their examination, will not have any leave of absence granted, but will be stationed at Chatham for two or three months, previously to being gazetted; and on their conduct there will depend their obtaining their commissions. The appointment of army-assistant surgeons rests with the director-general, Sir James M'Grigor, Bart., by whom the examinations are generally conducted.

NAVAL MEDICAL DEPARTMENT.—ADMIRALTY OFFICE, SOMERSET HOUSE.

Director-General of the Medical Department of the Navy, Sir William Burnett, M.D., Knt., K.C.H., F.R.S.

Qualifications.—The Right Hon. the Lords Commissioners of the Admiralty having been pleased to direct "that no person be admitted as an assistant-surgeon in the Royal Navy who shall not produce a certificate from one of the Royal Colleges of Surgeons of London, Edinburgh, or Dublin, of his fitness for that office; nor as a surgeon unless he shall produce a diploma or certificate from one of the said royal colleges, founded on an examination to be passed subsequently to his appointment of assistant-surgeon, as to the candidate's fitness for the situation of surgeon in the navy; and, in every case, the candidate producing such certificate or diploma shall also undergo a further examination before the director-general of the medical department of the navy, touching his qualifications in all the necessary branches and points of medicine and surgery for each of the steps in the naval medical service," the inspector-general doth hereby signify, for the information of those persons to whom it may relate, that these regulations and directions will be strictly adhered to; and further, that, previously to the admission of assistant-surgeons into the navy, it will be required that they produce proof of having received a preliminary classical education, and that they possess, in particular, a competent knowledge of Latin; also, that they are of good moral character, the certificate of which must be signed by the clergyman of the parish, or by a magistrate of the district. That they have served an apprenticeship, or have been engaged for not less than six months in practical pharmacy. That their age be not less than twenty years, nor more than twenty-four, and that they are unmarried. That they have actually attended a hospital London, Edinburgh, Dublin, Glasgow, or Aberdeen, for two years, after the age of eighteen, in which the average number of patients is not less than 150. That they have been engaged in actual dissections of the human body twelve months; the certificates of which, from the teacher, must state the number of subjects or parts dissected by the candidate. That they have attended lectures, &c., on the following subjects, at established schools of eminence, by physicians or surgeons of the recognised colleges of physicians or surgeons in the United Kingdom, for periods not less than hereunder stated, observing, however, that such lectures will not be admitted if the teacher shall lecture on more than one branch of science, or if the lectures on anatomy, surgery, and medicine, be not attended during three distinct winter sessions of six months each.

Anatomy (or general anatomy, twelve months; and comparative anatomy, six months), eighteen months.
months
months. Theory of medicine, six months. Practice of medicine, twelve months. If the lectures on the theory and practice of medicine are given in conjunction, then the period required is eighteen months (six months' lecture on pathology, if given at a university where there may be a professorship on that branch of science, will be admitted in lieu of six months' lectures on the practice of medicine). Clinical lectures, at a hospital as above (or the practice of medicine, six months; and the practice of surgery, six months), twelve months. Chemistry (or lectures on chemistry, three months, and practical chemistry, three months), six months. Materia medica, six months. Midwifery (accompanied by certificates stating the number of midwifery cases personally attended), six months. Botany (or general botany, three months; and medical botany, three months), six months.

In addition to the tickets for the lectures, certificates must be produced from the professors, &c., by whom the lectures were given, stating the periods (in months) *actually* attended by the candidates. The time, also, of actual attendance at a hospital or infirmary must be certified, and the tickets as well as certificates of attendance, age, moral character, &c., must be produced by the candidate immediately on his being desired to appear for examination.

Although the above are the only qualifications which are absolutely required in candidates for the appointment of assistant-surgeon, a favourable consideration will be given to the cases of those who have obtained the degree of M.D. at either of the universities of Oxford, Cambridge, Edinburgh, Dublin, Glasgow, or London, or who, by possessing a knowledge of the diseases of the eye, and of any branch of science connected with the profession, such as medical jurisprudence, natural history, natural philosophy, &c., appear to be more peculiarly eligible for admission into the service, observing, however, that lectures on these or any other subjects cannot be admitted as compensating for any deficiency in those required by the regulations.

By the rules of the service, no assistant-surgeon can be promoted to the rank of surgeon until he shall have served three years in the former capacity, one year of which must be in a ship actually employed at sea; and it is resolved that not any diploma or certificate of examination from either of the aforesaid royal colleg shall be admitted toward the qualification to surgeon unless the diploma or certificate shall obtained on an examination passed after od of not less than three years' actual servi ng that no one can be admitted to an nation for surgeon unless he be a member o of the above-named royal colleges; and wh assistant-surgeons, already in the service (wh e professional education may not be in accordan with the above), obtain leave to study previously to their passing for surgeon, they will be required. their examination, to produce testimonials of their having availed themselves of the period of leave to complete their education, agreeably to these regulations.

It is also to be observed, that candidates who may be admitted into the naval medical service must serve in whatever ships, &c., they may be appointed to, and that, in the event of their being unable to do so from sea-sickness, their names cannot be continued on the naval medical list, nor can they, of course, be allowed half-pay.

ORDNANCE MEDICAL DEPARTMENT.—63, PALL-MALL.

Regulations for the Admission of Candidates.—*Provisional List.*—Medical students who have completed their twentieth year, who have been well instructed in the Latin and Greek languages, the elements of mathematics and natural philosophy, and who can produce satisfactory proofs of being of good moral character, and diligent in the study of their profession and the sciences connected with it, may be entered in the provisional list of gentlemen desirous to be admitted candidates for employment in the Ordnance medical department. A knowledge also of modern languages, though not indispensable at the time of provisional reception,

the list of candidates

retained on it after he is twenty-five, years of age.

The age of every individual must be verified by a certificate of his baptism, if it can be procured. He must be also unmarried, and in the full enjoyment of health, both bodily and mental.

Qualifications. Every candidate must produce a diploma from one of the colleges of surgeons of London, Edinburgh, or Dublin; and a certificate of qualification from the Society of Apothecaries in London. He must also bring proof of having diligently gone through the following branches of professional education, nearly all of which are required to enable him to take out the above-mentioned diploma and certificate—viz., of having served an apprenticeship of five years to a surgeon and apothecary, if educated in England; but if

Bright, Addison, Babington, Barlow Hughes, Owen Rees, and Golding Bird. *Pupil*, for eighteen months, £15 15s.; for longer period, £24 4s.—*Surgeons:* Messrs. B. Cooper, Key, Morgan, Callaway, Cock, and Hilton. *Practice*, 50 Guineas.

not, qualification in the practice of medicine and pharmacy equivalent thereto;—of having attended the practice of surgery in a recognised hospital or hospitals, where clinical instruction is constantly given for three years, three months being allowed for a vacation in each year;—of having attended the undermentioned lectures, &c.:—

Anatomical lectures. Ditto—demonstrations. Ditto—dissections	Three anatomical seasons or sessions.
Morbid anatomy and pathology	one course.
Lectures on the principles and practice of surgery, delivered in two distinct periods or sessions	two courses, each comprising seventy lectures, on one course of surgery, and one of military surgery.
Natural history, or comparative anatomy	one course.
Chemistry	one course of a hundred lectures.
Botany	one course.
Materia medica and therapeutics	one course of a hundred lectures.
Lectures on the principles and practice of medicine	two courses, each a hundred lectures; second and third winters.

Medical practice, with clinical lectures, eighteen months, commencing the second session, viz., twelve months in a recognised hospital, and the remaining six months either in a recognised hospital or a dispensary.

Medical jurisprudence, with toxicology	one course of fifty lectures.
Midwifery	two courses each of lectures, second and third sessions.
Practical midwifery (not less than thirty cases)	After the conclusion of the first course of midwifery lectures, a certificate of having passed the usual examination is to be produced.
Diseases of the eye (with attendance on patients of that class)	one course.

He must produce a diploma from either of the colleges in London, Edinburgh, or Dublin, and, if not a graduated M.D. of Scotland or Ireland, after having actually passed an examination in the university where he has obtained his degree, a certificate of qualification also from the Society of Apothecaries in London. It is likewise expected that candidates shall have attended establishments for the cure of diseases of the ear and skin, and for the treatment of patients affected with mental derangement. Certificates will not be received on more than two branches of science, from one and the same lecturer; but anatomy and physiology, demonstrations and dissections, materia medica and botany, will be respectively considered one branch of science. In the certificates of attendance on hospital practice, and on lectures, the dates of commencement and termination are to be inserted in words at full length. The moral conduct and character of each individual must be certified by the gentleman to whose care his education was confided; and also by a clergyman, who, if practicable, should be the incumbent or officiating minister of the parish in which the applicant usually resides. The documents above detailed are to be inspected by a board, to consist of not less than five medical officers, after which they are to examine the candidate as to his professional acquirements. If his education has been chiefly medical, the examination will be principally in practical surgery; but if surgical, in the theory and practice of physic, including pharmacy. The full qualification being required on admission, a second examination is deemed unnecessary.

EAST INDIA COMPANY'S SERVICE.—REGULATIONS FOR THE ADMISSION OF MEDICAL GENTLEMEN INTO THE EAST INDIA COMPANY'S SERVICE AS ASSISTANT-SURGEONS FOR INDIA.

Age.—The assistant-surgeon must not be under twenty-two years, in proof of which he must produce an extract from the register of the parish in which he was born.

Qualifications in Surgery.—The assistant-surgeon, upon receiving a nomination, will be furnished with a letter to the Court of Examiners of the Royal College of Surgeons, to be examined in surgery, and their certificate will be deemed a satisfactory testimonial of his qualification; but should the assistant-surgeon be previously in possession of a diploma from the Royal College of Surgeons of London, or of the College of Surgeons of Dublin or Edinburgh, or of the College and University of Glasgow, or of the Faculty of Physicians and Surgeons of Glasgow, either of them will be deemed satisfactory as to his knowledge of surgery, without any further examination. He is also required to produce a certificate from the cupper of a public hospital in London, of having acquired and being capable of practising with proper dexterity the art of cupping.

Qualifications in Physic.—The assistant-surgeon will also be required to pass an examination by the Company's examining physician in the practice of physic, and to produce satisfactory proof of his having attended at least two courses of lectures on the practice of physic; and, above all, that he should produce a certificate of having attended diligently the practice of the physicians at some general hospital in London for six months.

The assistant-surgeon is also required, as a condition to his appointment, to subscribe to the Military or Medical and Medical Retiring Fund at his respective presidency, and also to the Military Orphan Society, if appointed to Bengal.

The assistant-surgeon is required, by a resolution of court of the 21st of May, 1828, to apply at the office for cadets and assistant-surgeons for his orders for embarkation, and actually proceed under such orders within three months from the date of being passed and sworn before the committee for passing military appointments; he will then be furnished with an order to obtain the certificate of his appointment, signed by the secretary, for which he will pay a fee of £5 in the secretary's office.

Assistant-surgeons who shall fail to apply at the cadet apartment for their orders within three months from the date of their being passed and sworn before the committee, or shall not actually proceed under such orders, are considered to have forfeited their appointments, unless special circumstances justify the court's departure from this regulation.

APOTHECARIES' HALL.—Gentlemen admitted members on Thursday, September 17:—Robert Thomas Martland, Francis Barlow, William Fancourt Tomkins, Joseph Clegg, Charles Sturges, and James Hunter Blair Sandon.

WAR-OFFICE, Sept. 18.—44th Foot: To be Assist.-Surg., Edward Robertson, M.D., from the 69th Foot, to be Surg., vice Murray, promoted on the Staff. To be Assistant-Surgeon: Assist.-Surgeon, Robert Villiers George, M.D., from the 3rd West India Regiment, vice Robertson, promoted in the 44th Foot. Hospital Staff: Surg. Denis Murray, M.D., from the 44th Foot, to be Staff Surg. of the First Class, vice Charles Quarterly Palmer, who retires upon half-pay.

HOSPITAL STAFF.—Surgeon William Carson, M.D., from the 1st Foot, to be Staff Surgeon of the Second Class, vice Knox, who exchanges; Dowell O'Reilly Clayton, M.D., to be Assistant Staff Surgeon, vice Traquair, who resigns.

NAVAL APPOINTMENT.—Dr. Thomas Graham, Assistant-Surgeon to the Madagascar.

NAVAL INTELLIGENCE—PROMOTION.—Oliver Thomas Miller, Assistant-Surgeon, Vindictive, to be Surgeon to the Vesuvius.

Mr. O. Smee, F.R.S., surgeon to the Bank, is about to bring out, in an octavo volume, some important observations on the potato disease. Mr. Smee's views extend not only to the theory of the question, but to the practical application of remedies in every case—in Mr. Smee's opinion, efficacious.

The first case of cholera at Teheran appeared in that part of the town which is nearest to the direction followed by the miasma.

TO CORRESPONDENTS.

A Subscriber.—*The appointment took place in 1838. Mr. Stirling was the person succeeded.*

Mr. Brown.—*The petition against the registration bill has been received. We are unable to notice it this week, on account of the press of matter inseparable from our publishing the index and students' number.*

Many gentlemen who have written volunteering further information, in answer to our application for the prospectus of the schools with which they are connected, are thanked for their attentive politeness.

A Charing-Cross Student *has attended the lectures required by the College of Surgeons, with the addition of medical practice, which they do not require. He can try the effect of petitioning the Society of Apothecaries, however, although we do not think he should be sanguine respecting the result.*

A Constant Subscriber *has sent us the handbill of an institution at Pimlico, which professes to provide the labourer and mechanic with every attention his case may demand without any fee being required, unless medicine be necessary, in which case the retail price of the drugs only will be charged. We regret to see such an establishment disgracing the neighbourhood of Pimlico.*

A Student.—*The work named is a very good one. We have already recorded our opinion of "Chelius' Surgery."*

Mr. Sabben.—*The work was reviewed from the French.*

An Experienced Surgeon's *communication has been received.*

Numerous communications have been received. We are precluded from noticing the greater number by press of matter.

Several gentlemen whose advertisements are unavoidably omitted this week, *in consequence of our publication of the Students' Number, are requested to accept our excuses.*

H. P.—*The abuse stigmatised at the University College Hospital deserves and shall receive attention.*

Vindex.—*The committee of inquiry at St. Pancras have decided, after patient investigation, that the charges were groundless.*

The "Ten Towns' Messenger" *has been received.*

The "Leicester Journal" *contains an account of a meeting held at the Leicester Infirmary, at which the following resolution was, after considerable discussion, carried by a small majority.—"That a committee be appointed to examine into the whole question of the medical arrangements of the Leicester Infirmary; to compare the existing rules with the prevailing practice, and to consider whether any and what alterations may be made to increase the efficiency of the charity, and to promote the ends of medical and surgical science; that they be requested to report the result of their proceedings to the next annual meeting, and to give such notices at the preceding Quarterly Board as shall enable the Governors to carry their recommendations into effect."*

THE MEDICAL TIMES.

SATURDAY, SEPTEMBER 26, 1846.

THE NATIONAL INSTITUTE.

THE political prospects of our profession were never more auspicious than at this moment. When an enemy grows abusive we may begin to believe in our own prosperity, since it is in the nature of envy to sicken at the triumphs in foes itself has vainly attempted to achieve. The National Institute is no sooner established, and gaining the confidence and support of all men of public spirit, when an eccentric individual who has, for months past, lain concealed like a baffled beast of prey, suddenly starts into the daylight, and exhausts his foolish fury in personal vituperation and polemical rancour. This very odd person has, on his old plan, sought to disparage the National Institute by wilful perversions of the truth, gratuitous assumptions, and dishonest arguments. Like the bush-fighters in Southern Africa, he lies in ambush for his antagonist, to strike a blow at a critical moment, under any temporary advantage; his weapon the poisoned arrow; his strategy the instinct of cowardice; his counsel the instigation of falsehood.

It is scarcely necessary to warn our readers against approaching the desolate shrine of moral pollution, the scene of these frantic ravings. Who knows not that its influence has a magic power of blighting all of character that advances within the unclean circle? That nothing prospers within its unholy limits; that its praises are calumnies which undo a man; that its support is certain ruin; its proximity, moral disease and desolation?

We are impudently told (*thence !*) that the *New Institute* is on precisely the same plan as the *British Medical Association*, the *Association of Surgeons*, and the *Medical Protection Assembly*. "A living dog is better than a dead lion," we are told; but with this person our living lion is no better than his dead dogs.

Having made this notable discovery, he coolly informs us that the *New Institute* can do no more good than these dead ones have done; and he goes on to imply that no political or scientific association (for he has identified the Institute also with the Medico-Chirurgical Society) can ever benefit the profession. What, then! does this man deliberately confess himself to have been the most unprincipled hypocrite that ever bartered character for public notoriety? Was this man not a true member of the British Medical, the Protection, and the other Associations his connection killed; and has he not vaunted their merits and their utility just as surely as he destroyed them? He *discovers* (!) the National Institute to be upon the same plan (Heaven forefend it !), and with modest assurance he informs the profession that this body can effect nothing beneficial for the profession! What an amusing person!

Are all associations for political purposes valueless, then? Oh, no! He would *like*—very much like—to have a snug little coterie of his own, to whom he could prescribe laws, and dictate plans of operation. Fifty shameless attempts *are unsuccessful*—only suggest the fifty-first! There is a Medical Registration Bill to be passed, and there must be a little machinery organized to give a countenance to the scheme; for he is yet not tired of forcing himself on the profession, after a thousand rebuffs. Then, as money is the sinews of war, a subscription must be entered on, and the munificent sum of half-a-crown per head is requested to be forwarded to a central board *in nubibus*. It is by such a peddling affair as this—equalled only by the penny subscription got up by five innkeepers in Camden-town to meet the same worthy's political necessities—that the profession are to be seduced from their noble enterprise.

We suggest that the innkeepers forming the penny-subscription committee will unite with their half-crown brethren in mendicancy, and thus save the unnecessary expense of divided labours. This individual's operations must ever revolve in a circle of which an intense selfishness is the centre of motion. Let him pursue his own ambiguous career, but let him not dare to asperse the motives or impede the movements of worthier men. If he attempt to cast a shadow upon the brightest prospect the expectant eyes of the profession ever viewed—to damp the purest enthusiasm, or belie the noblest aims, that ever distinguished an honourable society—WE WILL REVEAL! Is a society,—a whole profession—to be trifled with, bearded, and insulted, because a political adventurer is shut out from the enjoyment of that influence to which his previous conduct has entirely disentitled him? Is the destroyer of every society with which he had been connected to be welcomed into the new brotherhood? Is the snake, who has shot his envenomed tongue into the heart of his once blinded friends and most devoted coadjutors, to be again foolishly taken to the bosom? Such folly would indeed receive its own reward.

The National Institute, however, is *not* similar to any of the previous medical associations, in two or three essential particulars: the character of its development, the respectability of its leading members, and the large resources which it will be enabled to command. We do not wish to say a single syllable against the character or respectability of any member of our profession. It is a mean propensity to calumniate individuals, and we scorn it. We denounce the despot of public opinion--arrogant in mien, and low and unscrupulous in means—not because we fear him, but because it is a public duty. We will not breathe a suspicion upon men who, in accordance with the dictates of their intelligence, have been seeking for the acquisition of some public good. If, then, we say that previous associations were not composed of the same elements of respectabilty, we, to a great extent, state a fact which accounts for their failure. The best men temporarily connected with those associations have already joined the Institute, and of course their opinion, derived from experience, is, that the Institute *can* do some good. That it can do it, and will do it, we have no doubt. It must be remembered that the Institute, although framed upon the most liberal principles, is, essentially and associatively, a body of general practitioners. Herein consists its strength, and the promise of its success. The other societies were heterogeneous, cosmopolite masses, that tumbled to pieces at the first shock from without, or the first division within. There was no identity of interest, none of feeling, none of habit, none of end. The unity of the National Institute is its political characteristic.

The Institute has, hitherto also, been, in a pecuniary point of view, eminently successful—far more so, as respects the number of subscribing members, than the association from which it originated ever was; and five times more so than any other association established for similar purposes. An attempt has been made to rouse the fears of the profession, and to pander to the most sordid propensities of our nature, by holding out suspicions that a large call will be made upon the pockets of the members for the erection of a building and the formation of a museum and library, and all other appendages of a scientific body. Let not the members be alarmed. It will be their pride to form their own museum, by contributions of preparations in anatomy, pathology, and natural history, without, at all events, immediately raising a fund for these purposes. There are thousands of preparations scattered throughout the country in the surgeries, museums, and consulting rooms of the general practitioners. These will, doubtless, be placed upon the shelves of the *National Institute*. The same may be said of books. Duplicate copies of volumes will be deposited in the library of the new Institute, larger donations will follow, and a collection will soon be amassed that will redound to the high honour of our profession. Offers both of preparations and books have already been made from numerous quarters, and we have no doubt that a very few months will see the National Institute in the possession of a good library and museum, raised by the individual exertions, the untaxed donations, of its members.

It is self-evident, however, that a large success must depend upon an extensive support. Numbers are wanted, and with numbers funds will come. Let every man impress the importance of the success of this undertaking on his brother practitioner; let him make the business of the Institute his own; let him earnestly inculcate the expediency of the noble objects which the Institute is founded to embrace and achieve; let him go to his work in a proselytizing spirit—as a man convinced of the truth of his own opinions, and burning for the welfare and honour of his profession We saw an account a few days since of the London Trades' Unions, containing seventy-five members, established two years only, and already with £100 in the funds. Lectures are given, discussions held, the periodicals are taken in, a library is formed, and essays on the most important commercial and civil relations of the subject are read; and, notwithstanding the outlay required for these objects, a hoard is gradually accumulating for the accomplishment of yet more permanent advantages. Let us learn

a lesson from the humble, and show ourselves worthy of that enlightened and emulous spirit that characterizes our age. Independence of thought is a necessary step to this end; and let us fortify that spirit of boldness and truth that will not hesitate to pursue the Marplot to his chamber of intrigue, and rebuke the reviler in the moment of his wrath.

The professive calumniator is clearly smarting under some hidden wound; his galled spirit winces, although he is unwilling to acknowledge the torture. The Registration Bill was rejected; *hinc illæ lachrymæ!* He is sunk in shame and vexed by defeat, and he would fain revive his disconsolate spirit. It is a remarkable thing that a man who has possessed so many opportunities of gaining experience, should so rashly place himself in ridiculous situations. Drunk with self-love, he reels to the ground before the reproving eye of the world, and, like a bloated Bacchus, writhes, foams, and roars for some friendly hand to lift him out of the mire in which he wallows. A most unhappy fatality tracks his progress; at each step he slips aside; and, with each attempt at recovery, his fall becomes more imminent. Are we severe? We intend to be so. An irreconcileable public enemy deserves no quarter. An insidious, daring, and revengeful opponent requires a keen blade dealt with a heavy hand for his chastisement. But let him go; we have already spent too much time in lowering a man who has already lowered himself far deeper than we could ever precipitate him.

Although an exposure of baseness is sometimes necessary to prevent virtue suffering contamination and *defeat*, yet it is not by such means that any great advance has ever been made in promoting the welfare of society and elevating the character of its institutions. Reproof is a reluctant duty; the expression of liberal sentiments is the natural evolution of the heart. It is only as we seek to establish the truth in its more amiable, ennobling, and sympathetic tendencies and manifestations, that we succeed in making any real progress in public amelioration, or consolidate any permanent benefits. This is our mission, and the mission of all who, engaging in the great cause of professional emancipation and of social elevation, expect to be honoured with success, and to be rewarded with the approbation of their brethren for their labours. We would teach forbearance, amenity, good faith, freedom from prejudice, a delicate sense of honour, mutual services, and a love of the profession which, by our membership, we are called upon to honour and dignify in ourselves. This is our duty, as doubtless it is our desire. Let these ethical principles be well established, and we shall deride the seductions of a political mercenary, and regard with scorn the machinations of a self-seeking Marplot.

"Impurus aer spiritus dejecit, infecto corde gigni morbos."—PAULUS.

"Qualis aer, talis spiritus; et cujusmodi spiritus humores."—ÆLIANUS MONTALTUS.

THE actual meaning of these mottoes is to some extent wide of the truth; but there is still a great deal of reality about them. Meteorology, despite all that has been done for it, is yet in its infancy, at least in so far as it relates to the living world. The conditions of the atmosphere, as regards density, dryness, humidity, and impregnation with foreign matters, are as demonstrable as a rule in arithmetic—there is even a law of storms; and whilst the mariner can predict wind and rain—the quarter and the quality of them—the philosopher, in his study, is not altogether ignorant of the forthcoming operations of atmospheric electricity. Our intercourse with the invisible fluid surrounding us is little short of the definiteness and certainty with which we can investigate the nature and properties of other more tangible bodies. We can decompose and recompose it, confine it in a given space, make it lighter or heavier, moist or dry, hot or cold, noxious or innocuous, at will; in fine, we have as much power over, and as much knowledge of, any selected portion of it as of almost any other ingredient of the inorganic world. And yet there is a vast something about it of which we know nothing at all.

Take an easterly wind, differing in no appreciable particular from its neighbours, and what a nuisance it is! All creation feels it, as it sweeps like a pestilence along! Flowers droop, and lose their brightness, and leaves shrivel, when it touches them. Let it glide ever so gently over the surface of a lake, and the cold-blooded fish avoids the shallows, and sinks into the depths of its native element, as though death floated on the water. In vain the angler tries his every artifice—the fish have lost their appetite, activity, and merriment—they will hide until the enemy shall have passed by. All animals have a horror of it; even a donkey is delicate enough to turn his back upon it; cows, horses, sheep, and even pigs, give it their posteriors to ply against. Man abhors it as he would a demon. Who ever heard of anybody being happy in an easterly wind? We should like to know whether any disciple of Momus ever fairly laughed in its face? We don't believe that the old founder of fun himself could have done such a thing. It broods like a nightmare upon one's spirits. Next to an evil conscience, there is no curse like it. It might have been sent on purpose "to make our bosom's lord sit heavily on his throne." Ask the hypochondriac how he feels under its fostering influence? He would answer in some such phrase as this:—

"Soluta mihi sunt omnia membra—
A capite ad calcem, sensusque omnisperiit
De pectore, tam immensus stupor animum invasit mihi."

It is in vain to ply your remedies against gout and rheumatism in an easterly wind. Patients respond to it like barometers. Try colchicum, calomel, opium, hot baths, no matter what—you have your trouble for nothing. Does anybody know what an easterly-wind headache is? We do; and only wish we knew how to describe it. It is one of those real, unmistakeable, downright tortures, compared with which most others are mere copies. It is equal to bowel complaint, tic douloureux, and toothache, all crammed into one! Moreover, it admits of no cure. It may condescend to go away, *sua sponte*, when the wind changes; but croton oil, of the very strongest, could not carry it off till then. Ask the old lady with the corns, what she thinks of an easterly wind? Depend upon it, she'll soon tell you where the shoe pinches. Ask the same question of the young lady with the taper waist, and, if she tell the truth—which, if you are a man of the world you will wonder at—she will delicately hint of a pain in her side. Don't venture the same interrogatory to an old maid turned of forty, unless you are her medical attendant. Such a query, in such a quarter, should be considered strictly *professional*.

We are not aware whether suicides and other crimes are more common when the wind is in the east, but we could readily believe it. Moreover, this nondescript Eurus occasionally brings with it a bane, quite equivalent in mischief to itself.

"Miramur quis sit tantus, et unde vapor!"

Nobody knows what it is, but in England we call it *blight*. It is a terrible something to the vegetable world, upon which it never alights but to leave death as a memento of its visitation. Husbandmen can tell of its approach, and can always trace its ravages; but beyond this, they have no knowledge whence it comes, or whither it goes, or how it carries on its career of destruction. But they are as wise as the philosopher, for he is as ignorant of it as the hind. Chemistry and pneumatics have nothing to say concerning it—it reveals none of its secrets to them—they have investigated, but all in vain.

Why is it that the east is so unlike every other wind that blows? Its opposite neighbour, is a goodly sort of breeze, that is acceptable to all folks, except such as owe their personal safety to the shortness of their passage across the Atlantic. Except with these, the gentle, genial zephyr is a favourite with everybody. It is the physician's sheet-anchor for the dissipation of coughs, colds, hoarseness, and headache. The south, again, with all its hydropathic tendencies, and an occasional bluster that has something of the bully in it, is yet far from disagreeable; and dangerous to nothing, except ships that are not seaworthy.

From the north, an atmospheric current may come, and, if single-handed, with impunity. It may redden one's nose, and pinch one's fingers, cause a little all-overishness, and suggest the desirableness of "comforters," thick-soled shoes, worsted stockings, and something stronger than cold water—but what of all this? A fine, clear, sharp, frosty day, is always acknowledged to be a "bracer" of animal spirits. To our taste, there is nothing like it for begetting an honest appetite and an easy digestion. It is an opportunity for merriment, good humour, and good health, all the world over.

But only let our northern visitant ally himself, as he comes along, with his left-hand neighbour, and he is directly contaminated by the contact. "Tell me what company you keep, and I will tell you what you are," never applied more truly to humanity, than it is capable of applying to sundry of our pneumatic visitants. A north-wester will do; but a north-easter is little better than a *simoon*. A current from the opposite hemisphere is as bad, if accompanied by its neighbour on the right. Only let that eastern sinner join issue with it, and then, farewell to all salubrity!

Not always, however, is the unhealthiness of climate, or season, due to the prevalence of east wind, or of its compounds. Take the present autumn, and the past summer, in illustration. Easterly winds have visited us not more commonly than usual, and yet, what sickness and mortality we have had! The farmer, on the whole, has fared tolerably well, if we except his potatoes and turnips. The former have early lost their vitality, as they lost it last year; and, as we said of them then, have *gone rotten*. It has been asked, what we mean by rotten? We mean, simply, that *decomposition, or play of chemical affinities*, which occurs in every vegetable or animal substance when its vital properties have left it, and it is placed in a certain atmosphere, and in a certain range of temperature! Nothing rots that has life in it; and living things are not easily preyed upon, to their total destruction, by parasites. The growths that are seen upon the so-called diseased potato, are a *consequence* of the death of the whole or part of it, and not the *cause* thereof. The mischief will be found in a *certain atmospheric condition*; and not in the idle parasite that is as common on logs of wood that have been exposed for years, as in the potato sprung from the seed of last spring. The *blight* and the *fly* have attacked the turnip—these are different from the "potato-disease," but they have a common origin with it. The great dearth of fruit, this season, is no doubt referable to the same cause. Nothing, in fact, has been up to the standard of health. A "taint" seems to have pervaded everything. Fish, flesh, and fowl—all have been complained of for their inferior quality. For the same reason, nothing would "keep," as butchers say. No matter what the temperature, an animal was no sooner dead than it began to decompose. Venison, instead of slowly acquiring a flavour by a few weeks' exposure, has regularly gone rotten, though placed in a draught and kept cool by artificial means! Gastronomists have been sad sufferers by this tendency to decomposition. Beer and ale, for the same reason, have been unfermentable, undrinkable, and as flat as ditch-water. Even milk, *properly so called*, has partaken of the same tendency to corruption, as batter puddings and baby's food have abundantly testified.

Has not this strange atmospheric condition had a share in producing the diarrhœa and dysentery that prevailed two months ago, and the low fever that prevails now? Our readers will recollect that, when Asiatic cholera was in London some years back, dead substances had a remarkable tendency to putrefaction. A piece of meat was sent up higher than St. Paul's, and yet it became offensive in a few hours. The atmospheric condition was, therefore, not confined to localities, but seemed to be general. It consists with our own experience to believe that there is the same prevalence now. We have occasionally observed that the inhabitants of ill-ventilated, ill-drained districts, who have been insufficiently clothed and fed, have suffered more fatally from diarrhœa and fever, than others better circumstanced; but they have not suffered singly. Amongst the best families, and in the best situations, we have seen the disease creep, and the rich and the poor have been made alike its victims! Nothing that domestic care and professional skill could do, to save those who were competent to pay any amount of money for either, served to secure them, in too many instances, from the ravages of the epidemic. Poverty might hasten its work of destruction—but affluence, with its concomitant privileges, purchased without scruple, furnished no exemption. As we have said, it is our belief that the *cause* is in some peculiarity of the atmosphere. We throw out the hint of investigation to those who have time and opportunity for the task. There is a secret something that is worth finding out.

MISCELLANEOUS CORRESPONDENCE.

THE GOWER-STREET SCHOOL.

[To the Editor of the Medical Times.]

SIR,—If you will have the goodness to give me your valuable advice, I shall feel truly obliged.

I came as a student to London, intending to enter at University College, but I hear accounts of the bad system which prevails there, and of the jobbing which takes place in several things. I find, too, that there are no regular demonstrations of anatomy, but that the papers are filled up irregularly, Mr. Quain refusing to sign them, but writing something at the end, at which the registrars laugh,—"he being a professor and not a demonstrator."

Would you advise me, then, to enter there, or to go to King's College, or Guy's, or St. Thomas's?

I am, Sir, yours most obediently,

JUNIUS.

PRACTICES AT THE UNIVERSITY COLLEGE HOSPITAL.

[To the Editor of the Medical Times.]

SIR,—Knowing the readiness with which, on all occasions, you exert your powerful influence in the correction of abuses, wherever existing, I beg leave to draw your attention to one in particular, as relating to a public charity, which has long required notice and severe animadversion. I allude to the very indiscriminate admission of persons to the Patients' Department of University College Hospital, so very many being received whose circumstances and situations in life by no means warrant any claim to assistance from such an Institution, and which a due sense of propriety should dictate. But I am sorry to say there are those who, governed by a sordid meanness, will resort to all manner of unbecoming schemes and paltry artifices, to obtain advice and assistance gratis; a practice which, in my opinion, cannot be too promptly or sternly checked. Is it consistent or proper with the purport and spirit of such an Institution, that patients should be hanging about the waiting-rooms in their silks and satins, with rings on their fingers, and other expensive ornaments of dress, receiving gratuitous medical advice and medicines? Such, however, is daily the case, and is a glaring and monstrous abuse of this or any similar charity, intended only for the relief of the needy and necessitous. Moreover, it is also used as a means of domestic economy to the families of *noblemen*, gentlemen, and wealthy tradesmen, with large establishments, who, for a trifling subscription of one guinea per annum, claim the privilege of inundating the hospital with their servants, assistants, and dependants; and not unfrequently branches of their own family. Added to this the frequent admissions, *and very marked attentions*, paid to the servants of private patients of the medical officers. Chronic cases, which are well known to be perfectly incurable, and persons with mere imaginary complaints, are prescribed for regularly, many months in succession, thus taking up much valuable time, which could be better given in attending to more worthy objects. And the waiting-room of the hospital is made a sort of lounge, by numerous young women, where they may gossip and make assignations with thoughtless and idle young students, of whom there are always plenty in a large medical school.

I am, Sir, your most obedient humble servant,

Sept. 21. AN OLD STUDENT.

GOSSIP OF THE WEEK.

Dr. W. B. Waterman, of Buffalo, has been sentenced to three years' imprisonment in the New York State Prison for disinterring bodies for anatomical purposes.

The root of the dahlia contains a bitter principle of so acrid a nature that its employment as food has always hitherto been despaired of. The "Journal de Chambery" states, however, that this bitter principle is removed by boiling much in the same manner as the potato is cooked. The dahlia root may therefore, it would appear, in some measure be substituted for the potato during the present scarcity.

The latest news from India brings reports up to the 2nd of August from Calcutta, and the 9th from Madras. It is stated by the Indian journals that the cholera rages with great violence at Kurratchee, and that 226 had died in two days; half of this number are said to have belonged to her Majesty's 86th Regiment of the line. No officers are reported to have died, but the natives have been cut off by hundreds. During the ten days, from the 14th to the 24th of June, 922 European and 600 native troops, and 7,000 inhabitants, are said to have died at Kurratchee. Burying and burning the bodies could not be proceeded with fast enough, so that mephitic exhalations had already begun to add to the causes of disease.

OBITUARY.—At Clay-cross, on the 16th inst., Mr. Charles Brown, surgeon, in his 77th year. On the 17th inst., at Worthing, C. F. Favell, M.D., of Sheffield. On the 9th inst., in his 27th year, Thomas Hugh Hesketh Davies, Esq., surgeon, Liverpool. At Corstorphine, on the 11th inst., Dr. William Henderson, in the 40th year of his age; much and deeply regretted. At Govan, on the 12th inst., Robert Austin, surgeon, Royal Navy. At Sheerness, on the 2nd inst., James Potter, M.D.

Mr. Samuel Barnes has resigned his office of Senior Surgeon to the Devon and Exeter Hospital.

MORTALITY TABLE.

For the Week ending Saturday, Sept. 26, 1846.

Causes of Death.	Total.	Average of 5 summers.	Average of 5 years.
ALL CAUSES........	863	898	968
SPECIFIED CAUSES...	861	892	961
Zymotic (or Epidemic, Endemic, and Contagious) Diseases..............	191	201	188
SPORADIC DISEASES.			
Dropsy, Cancer, and other Diseases of uncertain or variable Seat...........	101	99	104
Diseases of the Brain, Spinal Marrow, Nerves, and Senses................	124	155	157
Diseases of the Lungs, and of the other Organs of Respiration	214	227	204
Diseases of the Heart and Blood-vessels...........	20	23	27
Diseases of the Stomach, Liver, and other organs of Digestion	80	87	72
Diseases of the Kidneys, &c.	13	6	7
Childbirth, Diseases of the Uterus, &c.	9	9	10
Rheumatism, Diseases of the Bones, Joints, &c. ...	12	6	7
Diseases of the Skin, Cellular Tissue, &c.	2	1	2
Old Age.................	45	52	67
Violence, Privation, Cold, and Intemperance........	41	26	26
